b) UF scenario, under condition set #2, with alfuzosin as the one uroselective agent on the UF and BCF without Step Therapy was the next most cost effective UF scenario considered. However, under this UF scenario, without Step Therapy, the weighted average cost per day of therapy increased by 53% over the most cost effective UF scenario.

c) Any condition set that included tamsulosin on the UF was more costly compared to the baseline (what DoD pays today) weighted average cost per day of therapy.

A. COMMITTEE ACTION: UF RECOMMENDATION – In view of the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of the ABs, and other relevant factors, the P&T Committee, based upon its collective professional judgment, voted (15 for, 0 opposed, 1 abstained, and 2 absent) to recommend that: 1) alfuzosin be maintained as the uroselective formulary AB, and that terazosin and doxazosin be maintained as the non-uroselective formulary ABs; and; and 2) tamsulosin be classified as non-formulary under the UF with a PA requiring a trial of alfuzosin for new patients. (See paragraphs 7A, 7B and 7C on pages 37-43 of the P&T Committee minutes.)

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

B. COMMITTEE ACTION: PA CRITERIA – The P&T Committee voted (15 for, 0 opposed, 1 abstained, 1 absent) that the following PA criteria should apply for tamsulosin. Coverage would be approved if a patient met any of the following criteria (See paragraph 7D on pages 43-44 of the P&T Committee minutes):

1) Automated PA criteria:

   a) The patient has received a prescription for either tamsulosin or alfuzosin at any MHS pharmacy point of service (MTFs, retail network pharmacies, or mail order) during the previous 180 days.

2) PA criteria if automated criteria are not met:

   a) The patient has tried alfuzosin and had an inadequate response or was unable to tolerate treatment due to adverse effects.

   b) Treatment with alfuzosin is contraindicated.

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

C. COMMITTEE ACTION: MN CRITERIA – Based on the clinical evaluation for tamsulosin and the conditions for establishing medical necessity for a non-formulary

medication provided for in the UF rule, the P&T Committee recommended (15 for, 0 opposed, 1 abstained, 1 absent) MN criteria for tamsulosin. (See paragraph 7E on page 44 of the P&T Committee minutes.)

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

D. COMMITTEE ACTION: IMPLEMENTATION PERIOD –The P&T Committee recommended (14 for, 1 opposed, 1 abstained, 1 absent) 1) an effective date of the first Wednesday following a 60-day implementation period in the TMOP and TRRx, and at the MTFs no later than a 60-day implementation period. The implementation period will begin immediately following the approval by the Director, TMA. (See paragraph 7F on page 44 of the P&T Committee minutes.)

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

E. COMMITTEE ACTION: BCF RECOMMENDATION – The P&T Committee considered the BCF status of the AB agents. Based on the results of the clinical and economic evaluations presented, the P&T Committee voted (15 for, 0 opposed, 1 abstained, and 1 absent) to recommend that the current BCF listing for this class be maintained, requiring each MTF to carry terazosin and alfuzosin. (See paragraph 7G on page 44 of the P&T Committee minutes.)

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

8) DRUG CLASS REVIEW – TARGETED IMMUNOMODULATORY BIOLOGICS (TIBs)

The P&T Committee evaluated the relative clinical effectiveness of the targeted immunomodulatory biologics (TIBs) currently marketed in the United States. The TIB class comprises five medications covered as part of the TRICARE pharmacy benefit: adalimumab (Humira), anakinra (Kineret), etanercept (Enbrel), efalizumab (Raptiva), and alefacept (Amevive). Three similar biologic agents are not part of the pharmacy benefit due to their intravenous (IV) route of administration. Abatacept (Orencia), infliximab (Remicade), and rituximab (Rituxan). Like adalimumab and etanercept, infliximab is approved for multiple indications and in many respects directly competes with these two self-administered multiple indication agents. The IV agents were included in the review for comparative purposes only.

Since the FDA lacks regulatory authority to approve generic versions of biologic medications, generic formulations for the TIBs are not likely to appear in the near future. The TIB class accounted for approximately $136 million dollars in MHS expenditures in

FY 2007, primarily at the retail point of service (66%), followed by MTFs (19%) and mail order (15%). This estimate does not accurately represent utilization of the IV agents (e.g., infliximab), since these medications are commonly administered in clinic or office settings and are included on outpatient pharmacy profiles only in MTFs that choose to maintain such a record. The cost of treatment with these agents is high (on the order of $10,000 to $20,000 annually). There were approximately 11,500 unique TIB utilizers in the MHS in the most recent quarter (June to August 2007), not including patients receiving IV agents.

The majority of use of TIBs in DoD is for the two multi-indication agents (adalimumab and etanercept), not including patients receiving IV agents. Fewer than 4% of DoD TIB utilizers are receiving other TIBs. Over the entire patient population, adalimumab and etanercept are consistently used in about a 2:1 ratio, although utilization in the last quarter (June to August 2007) shows increased uptake of adalimumab among new users (new users only: 44% use of adalimumab vs. 54% use of etanercept, 2% other TIBs).

Relative Clinical Effectiveness Conclusion: The P&T Committee voted (16 for, 0 opposed, 0 abstained, 1 absent) to accept that

a) Across all disease states reviewed, all of the TIBs FDA-indicated for a particular condition have sufficient evidence from placebo-controlled randomized controlled trials (RCTs) to demonstrate efficacy. TIBs are typically added to standard therapy in patients with moderate to severe disease. In general, combination treatment of rheumatologic conditions with TIBs plus methotrexate (MTX) offers better efficacy than TIBs or MTX alone. Beneficial effects on quality of life and productivity are associated with improvements in clinical response.

b) There is a lack of direct comparative evidence (head-to-head RCTs) across all disease states. In all disease states except rheumatoid arthritis (RA), trials were too small in number or too heterogeneous to make indirect comparisons based on meta-analysis of placebo-controlled trials feasible. With two exceptions, treatment effect across agents appeared similar.

c) In RA, anakinra appears to be less efficacious than the TNF inhibitors (adalimumab, etanercept, and infliximab) with respect to effects on symptoms (American College of Rheumatology response), based on indirect comparison of data from placebo-controlled trials.

d) In psoriasis, PASI 75 scores for infliximab appeared consistently higher than with other TIBs used for psoriasis (etanercept, alefacept, and efalizumab), although there is insufficient comparative evidence to draw a definitive conclusion. Some evidence suggests diminishing effect with infliximab as continuous use approaches 1 year. PASI 75 response rates for alefacept, efalizumab, and etanercept appear similar in 12- to 24-week trials. An indication for adalimumab for the treatment of plaque psoriasis is under consideration by the FDA; one published trial and additional unpublished data available from the manufacturer support its efficacy for this condition.

e) The multi-indication self-administered TIBs (adalimumab and etanercept) compare favorably to one another. Etanercept did not appear to be efficacious in

Crohn's disease, for which adalimumab is indicated. Adalimumab lacks published evidence in juvenile rheumatoid arthritis (JRA) and has limited published evidence in psoriasis; however, the manufacturer has unpublished data suggesting efficacy in both disease states and both are under consideration by the FDA. For disease states in which both are indicated, there is little evidence to suggest any clinically relevant difference in treatment effect.

f) Alefacept and efalizumab are FDA-indicated only for psoriasis; they appear to compare favorably to etanercept in terms of treatment effect. Their place in therapy relative to etanercept and infliximab (and potentially adalimumab) in the treatment of psoriasis is probably dependent on factors such as intramuscular administration of alefacept, recommended lab monitoring with both agents, and greater familiarity of providers with the TNF inhibitors.

g) Overall, TIBs were well-tolerated during clinical trials; the most common and consistently reported AEs are injection site or infusion reactions (depending on route). Anakinra may cause more injection reactions than adalimumab and etanercept based on the mean crude incidence of injection reactions calculated by Oregon Health & Science University's Drug Effectiveness Review Program reviewers from clinical trials included in that review: 17.5% for adalimumab (95% CI 7.1-27.9); 22.4% for etanercept (95% CI 8.5-36.3); but 67.2% for anakinra (95% CI 38.7-95.7). In addition, anakinra is given once daily, as opposed to weekly or every other week dosing for adalimumab and etanercept.

h) The primary safety concerns with TIBs are related to the potential for increased risk of serious adverse events (e.g., infections, malignancies, autoimmune disorders, etc), most of which are associated with the drugs' effects on the immune system. These effects are rare and cannot be assessed reliably during clinical trials, although the overall incidence of serious adverse events tends to be higher with TIBs compared to placebo, and trends in large RCTs approach statistical significance. There is insufficient evidence to draw conclusions about comparative risk of any of these serious adverse events.

   i) There is fair evidence of an increased risk of serious infections (including tuberculosis) for TIBs compared to placebo.

   ii) Observational evidence indicates a higher risk of lymphoma for patients treated with infliximab or etanercept. Results of studies addressing other malignancies are mixed.

   iii) Evidence concerning the safety of TIBs in patients with chronic HF and the effects of TIBs on the development of chronic HF is mixed. Data from etanercept and infliximab RCTs evaluating these TIBs for the treatment of chronic HF suggested higher rates of mortality compared to placebo. However, observational studies have reported lower rates of cardiovascular events in RA patients on TNF inhibitors compared to those on conventional therapy.

   iv) All TNF inhibitors appear to cause the development of autoantibodies to some extent. Cases of drug-induced lupus, lupus-like syndromes and other

autoimmune disorders have been reported with etanercept, adalimumab, and infliximab.

v) Adalimumab, etanercept, and infliximab may be associated with demyelination. Hepatotoxicity has been reported with infliximab and alefacept.

vi) Laboratory monitoring is required or recommended for anakinra (neutrophil counts), alefacept (CD4+ T lymphocyte counts), and efalizumab (platelet counts) due to reports of hematologic abnormalities.

i) There is little substantive information concerning potential drug interactions with the TIBs, which are in general considered safe for use with the large number of drugs used concomitantly in clinical trials. Based on two combination trials (one with anakinra plus etanercept and one with abatacept plus etanercept), additive effects on the immune system appear to preclude concomitant treatment with more than one TIB.

j) Overall, TIBs do not appear to have major differences in terms of efficacy or safety/tolerability in specific subsets of patients (e.g., based on age, gender, race, or comorbid conditions), with the exception of a reported higher risk of mortality among chronic HF patients treated with etanercept or infliximab. Potential differences include varying pregnancy categories (B vs. C) across drugs (alefacept, abatacept, and rituximab are Category C); the need for dose reduction of anakinra in patients with impaired renal function; and availability of data in pediatric patients (etanercept for JRA; infliximab for pediatric Crohn's disease).

Relative Cost Effectiveness Conclusion: the P&T Committee concluded (16 for, 0 opposed, 0 abstained, 1 absent) that:

a) For RA, the clinical effectiveness evaluation concluded that anakinra appears to be less effective for the treatment of RA than the multi-indication TIBs. A cost effectiveness analysis comparing the expected cost per year of treatment across all three points of service for etanercept, adalimumab, and anakinra showed that adalimumab was the most cost effective TIB for treatment of RA. Etanercept was more costly than adalimumab with similar effectiveness, while anakinra was both more costly and less effective.

b) For psoriasis, there was insufficient evidence to definitely conclude that treatment effectiveness differed among agents. A cost analysis comparing the expected cost per year of treatment across all three points of service for efalizumab, etanercept, and alefacept showed similar cost effectiveness profiles for all three agents.

c) The UF scenario that placed adalimumab as the sole multi-indication TIB on the UF was the most cost effective scenario.

A. COMMITTEE ACTION: UF RECOMMENDATION – Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of the TIBs, and other relevant factors, the P&T Committee, based upon its collective professional judgment, voted (13 for, 2 opposed, 1 abstained, 1 absent) to recommend that adalimumab, alefacept, and efalizumab be maintained as formulary on the UF and that etanercept and anakinra be classified as non-formulary

under the UF. (See paragraphs 8A, 8B, and 8C on pages 45-59 of the P&T Committee minutes.)

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

B. COMMITTEE ACTION: MN CRITERIA – Based on the clinical evaluation and the conditions for establishing MN for a non-formulary medication provided for in the UF rule, the P&T Committee recommended (14 for, 0 opposed, 1 abstained, 2 absent) MN criteria for etanercept and anakinra. (See paragraph 8D on page 60 of the P&T Committee minutes.)

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

C. COMMITTEE ACTION: IMPLEMENTATION PERIOD – The P&T Committee recommended (15 for, 0 opposed, 1abstained, 1 absent): 1) an effective date of the first Wednesday following a 90-day implementation period at the TMOP and TRRx, and at the MTFs no later than a 90-day implementation period; and 2) TMA send a letter to beneficiaries affected by this UF decision.. The implementation period will begin immediately following the approval by the Director, TMA. (See paragraph 8E on pages 60-61 of the P&T Committee minutes.)

Director, TMA, Decision: □ Approved □ Disapproved

Approved, but modified as follows: *Approved as 120 days.*

D. COMMITTEE ACTION: PA REQUIREMENTS AND CRITERIA – Currently, PA criteria apply to four of the five TIBs: adalimumab, anakinra, efalizumab, and etanercept. The P&T Committee recommended (14 for, 0 opposed, 1 abstained, 2 absent) that 1) no changes be made to the PA criteria for etanercept, adalimumab, anakinra, and efalizumab, as outlined in Appendix C; 2) that a PA be required for alefacept under the PA criteria outline above; and 3) that the effective date for the alefacept PA be timed to coincide with that established for the UF decision in this class. (See paragraph 8F on page 61 and Appendix C on page 76 of the P&T Committee minutes.)

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

E. COMMITTEE ACTION: QLs – Currently, QLs apply to three of the five TIBs. adalimumab, anakinra, and etanercept. The P&T Committee recommended (14 for, 0 opposed, 1 abstained, 2 absent) that 1) no changes be made to existing QL/days

supply limits for etanercept, adalimumab, and anakinra. (See paragraph 8G on page 61 and Appendix C on page 74 of the P&T Commit\tee minutes.)

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

F. COMMITTEE ACTION: EXTENDED CORE FORMULARY (ECF) RECOMMENDATION – Based on the results of the clinical and economic evaluations presented, the P&T Committee voted (15 for, 0 opposed, 1 abstained, 1 absent) to recommend that adalimumab be added to the ECF. (See paragraph 8H on page 62 of the P&T Committee minutes.)

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

9) BCF STATUS OF ROSIGLITAZONE

The Pharmacoeconomic Center (PEC) updated the P&T Committee on the latest news/ evidence regarding the safety of the thiazolidinediones (TZD), particularly that of rosiglitazone, the DoD's BCF TZD. The P&T Committee discussed the advantages and disadvantages of removing rosiglitazone and rosiglitazone/metformin from the BCF. Ultimately, the P&T Committee determined that there was sufficient clinical evidence to justify removal of rosiglitazone and rosiglitazone/metformin from the BCF. (See paragraph 9 on page 62 of the P&T Committee minutes).

COMMITTEE ACTION: The Committee voted (13 for, 0 opposed, 1 abstained, 3 absent) to remove rosiglitazone and rosiglitazone/metformin from the BCF.

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

10) BCF / ECF REVIEW

As part of an ongoing plan to systematically review drug classes represented on the BCF, the P&T Committee made recommendations for clarifying BCF listings in two current BCF drug classes, analgesics (meloxicam, cyclobenzaprine, and oxycodone/ acetaminophen) and ADHD and narcolepsy agents (methylphenidate IR).

COMMITTEE ACTION: The P&T Committee recommended (14 for, 0 opposed, 1 abstained, 2 absent) the following changes to BCF / ECF listings. (See paragraph 10 on page 62 of the P&T Committee minutes and Appendix D on page 75):

Drug class or potential drug class	Current BCF/ECF listing	Recommendation	Vote			
			For	Opposed	Abstained	Absent
Analgesics	BCF – Meloxicam (Mobic) oral	Clarify BCF listing to "meloxicam tablets only"	14	0	1	2
	BCF – Cyclobenzaprine (Flexeril) oral; does not include 5 mg strength	Clarify BCF listing to "cyclobenzaprine IR tablets, 5 and 10 mg"	14	0	1	2
	BCF – Oxycodone 5 mg / acetaminophen 325 mg	Clarify BCF listing to "oxycodone 5 mg / acetaminophen 325 mg tablets"	14	0	1	2
ADHD and Narcolepsy Agents	BCF – methylphenidate IR; methylphenidate ER (specific brand is Concerta); mixed amphetamine salts ER (Adderall XR)	Clarify BCF listing to "methylphenidate IR (excludes Methylin oral solution and chewable tablets), methylphenidate ER (specific brand name is Concerta); mixed amphetamine salts ER (Adderall XR)"	14	0	1	2

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

11) STATUS OF AMLODIPINE ON THE UF

On an ongoing basis, the DoD PEC monitors changes in the clinical information, current costs, and utilization trends to evaluate whether the UF status of agents designated as non-formulary needs to be readdressed. At this meeting, the UF status of amlodipine (Norvasc, generics) was re-evaluated due to a significant decrease in cost across all three points of service.

Clinical Effectiveness Conclusion - At the August 2005 P&T Committee meeting, the Committee concluded that, in general, amlodipine had similar clinical effectiveness relative to other DHP CCBs in regards to efficacy, safety, and tolerability.

Cost Effectiveness Conclusion – The Committee voted (16 for, 0 opposed, 0 abstained, 1 absent) that amlodipine was the most cost effectiveness DHP CCB.

A. COMMITTEE ACTION: UF RECOMMENDATION – In view of the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of the DHP CCB, and other relevant factors, the P&T Committee, based upon its collective professional judgment, voted (15 for, 0 opposed, 1 abstained, and 1 absent) to recommend that amlodipine be reclassified as generic on the UF. (See paragraph 11A on page 63 of the P&T Committee minutes).

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

B. COMMITTEE ACTION: UF IMPLEMENTATION PERIOD – The P&T Committee recommend immediate implementation upon signing of the November 2007 DoD P&T Committee minutes by the Director, TMA. (See paragraph 11B on page 63 of the P&T Committee minutes).

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

C. COMMITTEE ACTION: BCF REVIEW AND IMPLEMENTATION - The P&T Committee considered the BCF status of the DHP CCB agents. Based on the results of the clinical and economic evaluations presented, the Committee voted (15 for, 0 opposed, 1 abstained and 1 absent) to add amlodipine to the BCF. (See paragraph 11C on page 63 of the P&T Committee minutes).

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

12) RE-EVALUATION OF NON-FORMULARY AGENTS

The P&T Committee's process for the re-evaluation of non-formulary agents established at the May 2007 meeting was approved by the Director, TMA on 24 June 2007. For this meeting, the PEC applied the appropriate criteria and defined a list of non-formulary drugs for re-evaluation of UF status (Table 3) for the P&T Committee's consideration. Accordingly, the P&T Committee reviewed a list of non-formulary drug agents identified that were: 1) from drug classes in which UF status was NOT awarded based on condition sets that specified the number of similar agents on the UF (i.e., agents in the same class or subclass); and 2) determined to have similar relative clinical effectiveness (i.e., similar efficacy, safety, and tolerability) compared to similar agents on the UF and not excluded from the UF based on clinical issues alone.

Accordingly, the PEC recommended that the following pre-established criteria be applied to each non-formulary agent for re-evaluation of UF status.

1) The non-formulary agent becomes generically available and:
   a) The generic product is "A-rated" as therapeutically equivalent to the brand name product according to the FDA's classification system
   b) The generic market supply is stable and sufficient to meet DoD MHS supply demands.
2) The non-formulary agent is cost effective relative to similar agents on the UF. A non-formulary agent becomes cost effective when:
   a) The non-formulary agent's total weighted average cost per day of treatment is less than or equal to the total weighted average cost per day of treatment for the UF class to which they were compared.
   b) The non-formulary agent's total weighted average cost based on an alternate measure used during the previous review is less than or equal to that for the UF class to which they were compared. For example, antibiotics may be compared on the cost per course of therapy used to treat a particular condition.

The PEC reminded the DoD P&T Committee that when the pre-established criteria for reclassification are met, the Chairperson of the P&T Committee will call for an electronic vote by the members of the P&T Committee on the matter.

1) Upon a majority vote affirming that the non-formulary drug should be reclassified as generic, that agent will be changed from non-formulary status to formulary status as a generic.

2) Committee members will be briefed on any reclassification of a non-formulary agent at the next meeting of the P&T Committee. This information will be recorded as an information-only item in the meeting minutes. The item will be included in information provided for the BAP's next meeting; however, since the BAP will have already made any comments on the subject, the item will normally not be subject to further BAP comment.

COMMITTEE ACTION: The P&T Committee voted (15 for, 1 against, 0 abstained, 1 absent) to recommend that the following list of non-formulary drug agents be re-evaluated for UF status when pre-established criteria are met. (See paragraph 12 on pages 63-65 of the P&T Committee minutes).

Generic Name	Brand Name	UF Class	Generics Shipping?
EE 30 mcg; 0.15 mg levonorgestrel	Seasonale	BCs (M30)	Y
EE 30/10 mcg; 0.15 mg levonorgestrel	Seasonique	BCs (M20)	N
EE 35 mcg; 0.4 mg norethindrone	Ovcon-35	BCs (M35)	Y
EE 50 mcg; 1 mg norethindrone	Ovcon-50	BCs (M50)	N
EE 20 mcg; 0.1 mg norethindrone	Loestrin 24 FE	BCs (M20)	N
ciclopirox	Loprox	AF-DERMs	Y
econazole	Spectazole	AF-DERMs	Y
moexipril	Univasc	ACEs	Y
quinapril	Accupril	ACEs	Y

S. Ward Casscells, M.D.

Department of Defense
Pharmacy and Therapeutics Committee Minutes
November 2007

1. CONVENING

The Department of Defense (DoD) Pharmacy and Therapeutics (P&T) Committee convened at 0800 hours on 14-15 Nov 2007 at the DoD Pharmacoeconomic Center (PEC), Fort Sam Houston, Texas.

2. ATTENDANCE

A. Voting Members Present

CAPT Patricia Buss, MC, USN	DoD P&T Committee Chair
LTC Brett Kelly, MSC, USA	DoD P&T Committee Recorder
CAPT William Blanche, MSC, USN	DoD Pharmacy Programs, TMA
Capt Jeremy King, MC	Air Force, OB/GYN Physician
Lt Col Brian Crownover, MC	Air Force, Physician at Large
Lt Col Charlene Reith, BSC *for* Col Everett McAllister, BSC	Air Force, Pharmacy Officer
CDR Walter Downs, MC *for* LCDR Michelle Perelló, MC	Navy, Internal Medicine Physician
LCDR Ronnie Garcia, MC *for* LCDR Scott Akins, MC	Navy, Pediatrics Physician
CDR David Tanen, MC	Navy, Physician at Large
CAPT David Price, MSC	Navy, Pharmacy Officer
COL Doreen Lounsbery, MC	Army, Internal Medicine Physician
MAJ Roger Brockbank, MC	Army, Family Practice Physician
COL Ted Cieslak, MC	Army, Physician at Large
LTC (P) Peter Bulatao, MSC *for* COL Isiah Harper, MSC	Army, Pharmacy Officer
CAPT Vernon Lew, USPHS	Coast Guard, Pharmacy Officer
Mr. Joe Canzolino, RPh.	Department of Veterans Affairs

B. Voting Members Absent

To be determined	Air Force, Internal Medicine Physician

C. Non-Voting Members Present

COL Kent Maneval, MSC, USA	Defense Medical Standardization Board
Lt Col Paul Hoerner, BSC, USAF	Deputy Director, DoD Patient Safety Center
CDR Kim Lefebvre, MSC	Defense Supply Center Philadelphia
Mr. Howard Altschwager	Deputy General Counsel, TMA
LT Thomas Jenkins, MSC, USN	TMA Aurora

D. Non-Voting Members Absent

Martha Taft	Health Plan Operations, TMA

E. Others Present

CDR Matthew Carlberg, MC, USN	DoD Pharmacoeconomic Center
Lt Col James McCrary, MC, USAF	DoD Pharmacoeconomic Center
LTC Chris Conrad, MC, USA	DoD Pharmacoeconomic Center
Maj Wade Tiller, BSC, USAF	DoD Pharmacoeconomic Center
Maj Josh Devine, BSC, USAF	DoD Pharmacoeconomic Center
CPT Josh Napier, MC, USA	DoD Pharmacoeconomic Center
Angela Allerman, Pharm.D.	DoD Pharmacoeconomic Center
Julie Liss, Pharm.D.	DoD Pharmacoeconomic Center
David Meade, Pharm.D.	DoD Pharmacoeconomic Center
Harsha Mistry, Pharm.D.	DoD Pharmacoeconomic Center
Eugene Moore, Pharm.D.	DoD Pharmacoeconomic Center
Shana Trice, Pharm.D.	DoD Pharmacoeconomic Center
Nancy Misel, RPh	Director, Air Force High Dollar Program
LCDR James Ellzy, MC, USN	Prospective DoD P&T Committee Chair
Lt Col Thom Bacon	TMA Pharmaceutical Operations Directorate
CDR Rob Hayes	USPHS/IHS
Melinda Neuhauser	VA PBM

3. REVIEW MINUTES OF LAST MEETING

A. Corrections to the Minutes – August 2007 DoD P&T Committee meeting minutes were approved as written, with no corrections noted.

B. Approval of August Minutes – Dr. Samuel Ward Casscells, III., M.D., approved the minutes of the August 2007 DoD P&T Committee meeting on October 17, 2007.

4. ITEMS FOR INFORMATION

TRICARE Management Activity (TMA) and DoD PEC staff members briefed the P&T Committee on the following:

A. Beneficiary Advisory Panel (BAP) Briefing – CAPT Buss, CAPT Blanche and LTC Kelly briefed the members of the P&T Committee regarding the August 2007 BAP meeting. The P&T Committee was briefed on BAP comments regarding the DoD P&T Committee's Uniform Formulary (UF) and implementation recommendations.

B. Implementation Status of UF Decisions – The PEC briefed the members of the P&T Committee on the progress of implementation for drug classes reviewed for UF status since February 2005.

5. REVIEW OF RECENTLY APPROVED AGENTS

A. Recently Approved Agents in Classes Not Yet Reviewed for the UF

The P&T Committee was briefed on one new drug which was approved by the FDA (see Appendix B). The P&T Committee determined that this new drug fell into a drug class that has not yet been reviewed for UF status; therefore, UF consideration was deferred until the drug class review is completed. The P&T Committee discussed the need for a quantity limit (QL) for formoterol fumarate inhalation solution (Perforomist), based on existing QLs for other oral inhalation products and recommendations for use in product labeling.

COMMITTEE ACTION: QL – The P&T Committee voted (15 for, 0 opposed, 1 abstained, 1absent) to recommend a QL for formoterol fumarate inhalation solution of 60 unit dose vials per 30 days, 180 unit dose vials per 90 days**.**

B. Renin Angiotensin Antihypertensive (RAA) – Valsartan/Amlodipine (Exforge)

1) Valsartan/Amlodipine Relative Clinical Effectiveness –The proprietary product Exforge contains the combination of valsartan (Diovan) with amlodipine (Norvasc). It is the first fixed-dose combination product containing an angiotensin receptor blocker (ARB) with a dihydropyridine (DHP) calcium channel blocker (CCB). Generic formulations of amlodipine are now commercially available.

The DoD P&T Committee previously reviewed several subclasses of the RAA drug class, including the angiotensin converting enzyme (ACE) inhibitors and ACE/diuretic combinations in August 2005, the ACE/CCB combinations in February 2006, the ARBs and ARB/diuretic combinations in February 2005 and May 2007, and the direct renin inhibitor aliskiren (Tekturna) in August 2007.

Fixed-dose combination RAA agents designated as UF are benazepril/amlodipine (Lotrel, generics), telmisartan/ hydrochlorothiazide (HCTZ) (Micardis HCT), candesartan/HCTZ (Atacand HCT), losartan/HCTZ (Hyzaar), lisinopril/HCTZ (Prinzide, Zestoretic, generics), captopril/HCTZ (Capozide, generics), benazepril/ HCTZ (Lotensin HCT, generics), enalapril/ HCTZ (Vaseretic, generics), and fosinopril/HCTZ (Monopril HCT, generics).

Valsartan/amlodipine is approved for treating hypertension in patients whose blood pressure (BP) is not adequately controlled with an ARB or DHP CCB administered as monotherapy. Although Exforge is not approved for the initial treatment of hypertension, there is no evidence to suggest that it would not be effective when used in that manner clinically.

With regard to efficacy, combining an ARB with a DHP CCB provides two differing mechanisms to reduce BP. Two randomized controlled trials (RCTs) in over 2,000 patients showed superior BP reduction and control with Exforge compared to valsartan and amlodipine administered as monotherapy, and compared to placebo. A trial in 130 patients with Stage 2 hypertension (>160/>100 mm Hg) found similar BP reductions when valsartan/amlodipine was compared to the fixed dose combination of lisinopril/HCTZ.

There are no clinical trials with valsartan/amlodipine that have evaluated clinical outcomes of reducing mortality, stroke, heart failure (HF) hospitalization, or need for renal dialysis/transplantation. However, valsartan and amlodipine individually have shown benefits in these areas, and there is no evidence to suggest that valsartan/amlodipine would not be beneficial here.

With regard to safety, the package labeling for Exforge reflects that of the individual components for adverse events, drug interactions, and black box warnings (e.g., teratogenicity concerns with ARBs). In clinical trials, the incidence of peripheral edema with valsartan/amlodipine was lower than that observed with amlodipine monotherapy.

Although not specifically evaluated in a controlled clinical trial with valsartan/ amlodipine, potential benefits to fixed dose combination drugs include reduced tablet burden, simplified drug regimens, increased patient convenience, and improved adherence to therapy.

Relative Clinical Effectiveness Conclusion – The P&T Committee concluded that, while valsartan/amlodipine offers a slight convenience to the patient in terms of decreased tablet burden and simplified medication regimen, it does not have a significant, clinically meaningful therapeutic advantage in terms of safety, effectiveness, or clinical outcomes over other antihypertensive agents included on the UF.

COMMITTEE ACTION: The P&T Committee voted (15 for, 0 opposed, 0 abstained, 2 absent) to accept the clinical effectiveness conclusion stated above.

2) *Valsartan/Amlodipine Relative Cost Effectiveness* – The P&T Committee evaluated the relative cost effectiveness of valsartan/amlodipine in relation to efficacy, safety, tolerability, and clinical outcomes of the other agents in the class, particularly the ARBs. Information considered by the P&T Committee included, but was not limited to sources of information listed in 32 CFR 199.21 (e)(2).

   A cost minimization analysis (CMA) was employed to evaluate the cost effectiveness of valsartan/amlodipine. The cost effectiveness of Exforge was evaluated relative to the following pairings of single ingredient agents (ARB plus amlodipine): telmisartan (the most cost effective UF ARB) plus amlodipine; candesartan (chronic HF indication UF ARB) plus amlodipine; valsartan plus amlodipine (single ingredient agents of Exforge).

   The results of the CMA showed that the projected weighted average daily cost of Exforge was significantly higher than the weighted average daily cost of the pairings of UF ARBs with amlodipine.

Cost Effectiveness Conclusion – The P&T Committee concluded that valsartan/ amlodipine is not cost effective relative to the other agents in the RAA class. The weighted average cost of combined individual agents (UF ARBs and generic amlodipine) is more cost effective relative to Exforge.

COMMITTEE ACTION: The P&T Committee voted (13 for, 0 opposed, 3 abstained, 1 absent) to accept the valsartan/amlodipine relative cost effectiveness analysis as presented by the PEC.

3) *Valsartan/Amlodipine UF Recommendation*

COMMITTEE ACTION: Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of valsartan/amlodipine, and other relevant factors, the P&T Committee, based upon its collective professional judgment, voted (12 for, 0 opposed, 3 abstained, 2 absent) to recommend that Exforge be designated as non-formulary on the UF.

4) *Valsartan/Amlodipine MN Criteria* - Based on the clinical evaluation of valsartan/amlodipine, and the conditions for establishing medical necessity (MN) for a non-formulary medication provided for in the UF rule, the P&T Committee recommended the following general MN criteria for Exforge:

   1) Use of the formulary alternatives is contraindicated.
   2) The patient has experienced significant adverse effects from formulary alternatives.
   3) The patient previously responded to the non-formulary agent, and changing to the formulary alternatives would incur unacceptable risk.

   The P&T Committee specifically noted circumstances under which criterion #3 might be considered: 1) post-myocardial infarction (MI) patients with previous angioedema or other intolerance to ACE inhibitors who are stabilized on valsartan/amlodipine and in whom changes in therapy to a formulary ARB plus amlodipine might result in destabilization or 2) chronic HF patients who are stabilized on valsartan/ amlodipine and in whom changes in therapy to a formulary ARB plus amlodipine might result in destabilization.

   COMMITTEE ACTION: The P&T Committee voted (14 for, 0 opposed, 1 abstained, 2 absent) to approve the MN criteria outlined above.

5) *Valsartan/Amlodipine Implementation Plan* – The P&T Committee recommended an effective date of the first Wednesday following a 60-day implementation period in the TRICARE Mail Order Pharmacy (TMOP) program and TRICARE Retail Pharmacy Network (TRRx), and no later than a 60-day implementation period at military treatment facilities (MTFs). The implementation period will begin immediately following approval by the Director, TMA.

   As part of the implementation plan, the P&T Committee also recommended that the TRICARE Management Activity (TMA) send a letter to beneficiaries affected by this UF decision to inform them about the change in formulary status for valsartan/amlodipine. A retrospective pharmacy claims analysis revealed that

approximately 2,400 DoD beneficiaries have filled a prescription for valsartan/ amlodipine in the previous quarter.

MTFs will not be allowed to have valsartan/amlodipine on their local formularies. MTFs will be able to fill non-formulary requests for this agent only if both of the following conditions are met: 1) the prescription must be written by a MTF provider; MTFs may (but are not required to) fill a prescription for valsartan/amlodipine written by a non-MTF provider to whom the patient was referred, and 2) MN is established.

COMMITTEE ACTION: The P&T Committee recommended (14 for, 0 opposed, 1 abstained, 2 absent): 1) an effective date of the first Wednesday following a 60-day implementation period in the TMOP and TRRx, and at the MTFs no later than a 60-day implementation period; and 2) TMA send a letter to beneficiaries affected by this UF decision. The implementation period will begin immediately following the approval by the Director, TMA.

C. Attention Deficit Hyperactivity Disorder/Narcolepsy Agent – Lisdexamfetamine dimesylate (Vyvanse)

1) *Lisdexamfetamine Relative Clinical Effectiveness* –Lisdexamfetamine (Vyvanse) is a new stimulant drug approved for treating attention deficit/hyperactivity disorder (ADHD) in children 6 to 12 years of age. In contrast to methylphenidate extended release (ER) (Concerta), mixed amphetamine salts ER (Adderall XR), and atomoxetine (Strattera), lisdexamfetamine is not currently indicated for treating adolescents and adults. Vyvanse and Adderall XR are manufactured by the same company; generic formulations of Adderall XR are anticipated in 2009.

   The ADHD and narcolepsy drugs were evaluated at the November 2006 DoD P&T Committee meeting. The UF designated ADHD drugs include the non-stimulant atomoxetine, and the stimulants dextroamphetamine (Dexedrine, generics), methamphetamine (Desoxyn), mixed amphetamines salts (Adderall, and generics; Adderall XR), and all oral formulations of methylphenidate (Concerta, all Metadate products, all Methylin products, all Ritalin products, and generics). Methylphenidate transdermal system (Daytrana) and dexmethyl-phenidate (Focalin and Focalin XR) were classified as non-formulary.

   With regard to efficacy, there is insufficient evidence to suggest that clinically relevant differences exist between lisdexamfetamine and other ADHD stimulant products. One randomized published trial in 290 children showed significant improvements in ADHD rating scales with lisdexamfetamine compared to placebo. A double-blind, placebo-controlled crossover study available only in abstract form showed significant reductions in observer ratings of ADHD behaviors (e.g., improved ADHD control) with either lisdexamfetamine or mixed amphetamine salts (Adderall XR) in 52 children compared to placebo; outcomes with Vyvanse were not directly compared to Adderall XR.

   With regard to safety, there is no evidence to suggest that the adverse event profile of lisdexamfetamine differs clinically from other amphetamine formulations, although no comparative trials are available. Up to 33% of patients

report appetite suppression. The package labeling for lisdexamfetamine carries the same black box warning as the other stimulants for tolerance, dependence, abuse potential and sudden cardiac death in children with pre-existing structural cardiovascular abnormalities. The drug interaction profile is the same as other ADHD stimulants, and lisdexamfetamine should not be used concurrently with monoamine oxidase inhibitors, due to the risk of hypertensive crisis.

With regard to abuse potential, lisdexamfetamine is a Schedule II controlled substance, as are the other ADHD stimulants (e.g., methylphenidate and amphetamines). Lisdexamfetamine is a pro-drug that is hydrolyzed in the gastrointestinal tract to dextroamphetamine and the amino acid l-lysine, and was thus designed to have less potential for abuse, diversion and overdose toxicity than amphetamine. Two unpublished studies reported the preference of lisdexamfetamine in a total of 50 drug abusers. At lisdexamfetamine doses less than 100 mg "likeability" scores on a Drug Rating Questionnaire scale were similar to placebo, while doses exceeding 100 mg showed similar likeability as with dextroamphetamine (the maximum recommended lisdexamfetamine dose currently marketed is 70 mg).

Relative Clinical Effectiveness Conclusion – The P&T Committee concluded that lisdexamfetamine does not have a significant, clinically meaningful therapeutic advantage in terms of safety, effectiveness, or clinical outcomes over other ADHD agents included on the UF.

COMMITTEE ACTION: The P&T Committee voted (16 for, 0 opposed, 0 abstained, 1 absent) to accept the clinical effectiveness conclusion stated above.

2) *Lisdexamfetamine Relative Cost Effectiveness* – The P&T Committee evaluated the relative cost effectiveness of lisdexamfetamine in relation to efficacy, safety, tolerability, and clinical outcomes of the other agents in the class, particularly the other once-daily ADHD stimulant medications. Information considered by the P&T Committee included, but was not limited to sources of information listed in 32 CFR 199.21 (e)(2).

   The ADHD stimulants include methylphenidate immediate release (IR) and ER and various immediate and ER formulations of amphetamines (dextroamphetamine, methamphetamine, mixed salts of amphetamine, and lisdexamfetamine). The comparators for the cost effectiveness analysis of lisdexamfetamine included the UF once daily formulations ADHD stimulants: methylphenidate (Concerta, Metadate CD, Ritalin LA), and mixed salts of amphetamine ER (Adderall XR).

   The relative clinical effectiveness evaluation concluded that there is insufficient evidence of a clinically meaningful difference between once daily stimulants for the treatment of ADHD. As a result, a CMA was employed to determine the cost effectiveness of lisdexamfetamine relative to the UF once daily ADHD stimulants.

   Results from the CMA revealed that the weighted average cost per day of therapy for lisdexamfetamine was similar to the other UF once daily ADHD stimulants.

Cost Effectiveness Conclusion – The P&T Committee concluded that lisdexamfetamine had similar relative cost effectiveness compared to the other UF once daily ADHD stimulants.

COMMITTEE ACTION: The P&T Committee voted (14 for, 0 opposed, 1 abstained, 2 absent) to accept the lisdexamfetamine relative cost effectiveness analysis as presented by the PEC.

3) *Lisdexamfetamine UF Recommendation*

COMMITTEE ACTION: Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of lisdexamfetamine, and other relevant factors, the P&T Committee, based upon its collective professional judgment, voted (13 for, 1 opposed, 1 abstained, 2 absent) to recommend that lisdexamfetamine be designated as non-formulary on the UF. This recommendation was primarily based upon the determination that lisdexamfetamine offers no significant, clinically meaningful therapeutic advantage over other once daily ADHD stimulants.

4) *Lisdexamfetamine MN Criteria* – Based on the clinical evaluation of lisdexamfetamine and the conditions for establishing medical necessity for a non-formulary medication provided for in the UF rule, the P&T Committee recommended the following general MN criteria for lisdexamfetamine.

   1) Use of the formulary alternatives is contraindicated.
   2) The patient has experienced significant adverse events from formulary alternatives.
   3) Use of formulary alternatives has resulted in therapeutic failure.

   COMMITTEE ACTION: The P&T Committee voted (14 for, 0 opposed, 1 abstained, 2 absent) to approve the MN criteria outlined above.

5) *Lisdexamfetamine Implementation Plan* – The P&T Committee recommended an effective date of the first Wednesday following a 60-day implementation period in the TMOP and TRRx, and at MTFs no later than a 60-day implementation period.

   As part of the implementation plan, the P&T Committee also recommended that TMA send a letter to beneficiaries affected by this UF decision to inform them about the change in formulary status for lisdexamfetamine. A retrospective pharmacy claims analysis revealed that approximately 2,800 DoD beneficiaries have filled a prescription for lisdexamfetamine in the previous quarter.

   MTFs will not be allowed to have lisdexamfetamine on their local formularies. MTFs will be able to fill non-formulary requests for this agent only if both of the following conditions are met: 1) the prescription must be written by a MTF provider; MTFs may (but are not required to) fill a prescription for lisdexamfetamine written by a non-MTF provider to whom the patient was referred, and 2) MN is established.

   COMMITTEE ACTION: The P&T Committee recommended (14 for, 0 opposed, 1 abstained, 2 absent): 1) an effective date of the first Wednesday

following a 60-day implementation period in the TMOP and TRRx, and at the MTFs no later than a 60-day implementation period; and 2) TMA send a letter to beneficiaries affected by this UF decision. The implementation period will begin immediately following the approval by the Director, TMA.

D. Contraceptive – Ethinyl estradiol 20 mcg/levonorgestrel 0.09 mg (Lybrel)

1) *Lybrel Relative Clinical Effectiveness* – The contraceptive drug class was reviewed in May 2006. Lybrel is a new contraceptive marketed in July 2007 that contains 20 mcg of ethinyl estradiol (EE) and 90 mcg of levonorgestrel. It is the first FDA-approved contraceptive formulation specifically packaged for continuous use. Active tablets are taken 365 days a year, with the intent of eliminating cyclical bleeding periods.

   Contraceptives containing 20 mcg of EE with 100 mcg of levonorgestrel (Lutera, Levlite or equivalent) are included on the Basic Core Formulary (BCF). The Lybrel product cannot be exactly duplicated by using conventional packages of Lutera or its equivalents, due to the 10 mcg difference in the levonorgestrel component; however this difference in the progestin content is of questionable clinical relevance.

   Contraceptives are traditionally available in conventional 28-day packaging containing 21 days of active tablets followed by seven days of placebo tablets, which leads to 13 cycles of withdrawal bleeding yearly. Some recently introduced oral contraceptives reduce the number of placebo tablets to four (Yaz, Loestrin-24 Fe), thus shorting the bleeding period, or extend the number of active tablets to 84, resulting in only four withdrawal bleeding periods per year (e.g., Seasonique, Seasonale). Continuous use of oral contraceptives may be beneficial in women with symptoms related to fluctuations in hormone levels (e.g., endometriosis or menstrual migraines) and in women desiring cessation of cyclical bleeding. Conventionally packaged contraceptives are commonly used on a continuous or extended cycle basis. Four conventional contraceptive packs are dispensed every 90 days, and the patient is instructed to discard the unneeded placebo tablets. This practice also provides access to the full array of oral contraceptive products, with varying estrogen levels and types of progestins.

   With respect to efficacy, there is no evidence to suggest that Lybrel would differ from other similar contraceptives. One head-to-head, open-label trial in 641 women that compared Lybrel with a traditional regimen of 20 mcg EE/100 mg levonorgestrel (Lutera, Levlite or equivalents) reported no difference in pregnancy rates after one year (zero vs. three, respectively). A non-comparative trial in over 2,000 women reported 23 pregnancies after one year (a rate of 1.55 per 100 user years), which is similar to pregnancy rates reported with other contraceptives containing 20 mcg EE.

   With respect to safety, breakthrough bleeding/spotting is common with all extended-cycle or continuous regimens, particularly in the first few months of use. In the non-comparative trial, 18.6% of women discontinued therapy because of uterine bleeding. However, this decreased over time (48% incidence of breakthrough bleeding at pack 3 vs. 21% at pack 13), and approximately 60% of

women achieved amenorrhea after one year. In the head-to-head trial mentioned previously, the incidence of common adverse effects (dysmenorrhea, nausea, and headache) was similar between Lybrel and the comparator (Lutera, Levlite or equivalents). The safety profile of Lybrel has not been evaluated for longer than two years.

Relative Clinical Effectiveness Conclusion: The Committee concluded that Lybrel did not have a significant, clinically meaningful therapeutic advantage in terms of safety, effectiveness or clinical outcome over other oral contraceptives included on the UF.

COMMITTEE ACTION: The P&T Committee voted (15 for, 0 opposed, 0 abstained, 2 absent) to accept the clinical effectiveness conclusion stated above.

2) *Lybrel Relative Cost Effectiveness* – The P&T Committee evaluated the relative cost effectiveness of ethinyl estradiol 20/levonorgestrel 0.09 (Lybrel) in relation to efficacy, safety, tolerability, and clinical outcomes of the other agents in the class, particularly other monophasic ethinyl estradiol 20 mcg (M20 EE) contraceptives. Information considered by the P&T Committee included, but was not limited to sources of information listed in 32 CFR 199.21 (e)(2).

   The relative clinical effectiveness evaluation concluded that Lybrel does not show compelling clinical superiority over currently available contraceptives on the UF in the M20 EE subclass. As a result, a CMA was employed to determine the cost effectiveness of Lybrel relative to other UF M20 EE agents (Sronyx, Lutera, Levlite-28, Aviane, and Lessina-28) used on a continuous cycle basis.

   The results from the CMA revealed that the weighted average cost per day for treatment for Lybrel is significantly higher than other UF M20 EE agents used on a continuous cycle basis.

   Cost Effectiveness Conclusion. The P&T Committee concluded that Lybrel is not cost effective relative to other UF M20 EE agents used on a continuous cycle basis.

   COMMITTEE ACTION: The P&T Committee voted (14 for, 1 opposed, 1 abstained, 2 absent) to accept the ethinyl estradiol 20/levonorgestrel 0.09 (Lybrel) relative cost effectiveness analysis as presented by the PEC.

3) *Lybrel UF Recommendation*

   COMMITTEE ACTION: Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of the M20 EE contraceptive agents, and other relevant factors, the P&T Committee, based upon its collective professional judgment, voted (14 for, 0 opposed, 1 abstained, 2 absent) to recommend that. Lybrel be designated non-formulary on the UF.

4) *Lybrel MN Criteria* – Based on the clinical evaluation of Lybrel, and the conditions for establishing medical necessity for a non-formulary medication provided for in the UF rule, the P&T Committee recommended the following general MN criteria for Lybrel:

1) The patient has experienced significant adverse effects from formulary alternatives.

2) Use of formulary alternatives has resulted in therapeutic failure.

The P&T Committee commented that these MN criteria could be expected to apply to Lybrel only rarely, given the wide variety of formulary oral contraceptives—including oral contraceptives containing 20 mcg of EE and 100 mcg of levonorgestrel—all of which can be used on a continuous basis by discarding unneeded placebo tablets. Both criteria would likely only apply to patients who have encountered difficulty with the process of discarding unneeded placebo tablets. The P&T Committee did not expect that the difference between 100 and 90 mcg of levonorgestrel was likely to result in any clinically predictable reduction in adverse effects.

COMMITTEE ACTION: The P&T Committee voted (14 for, 0 opposed, 1 abstained, 2 absent) to approve the MN criteria outlined above.

5) *Lybrel Implementation Plan* – The P&T Committee recommended an effective date of the first Wednesday following a 60-day implementation period in TMOP and TRRx, and no longer than a 60-day implementation period at MTFs. The implementation period will begin immediately following approval by the Director, TMA.

As part of the implementation plan, the P&T Committee also recommended that TMA send a letter to beneficiaries affected by this UF decision to inform them about the change in formulary status for Lybrel. A retrospective pharmacy claims analysis revealed that approximately 273 DoD beneficiaries have filled a prescription for Lybrel in the previous quarter.

MTFs will not be allowed to have ethinyl estradiol 20/levonorgestrel 0.09 (Lybrel) on their local formularies. MTFs will be able to fill non-formulary requests for this agent only if both of the following conditions are met: 1) the prescription must be written by a MTF provider; MTFs may (but are not required to) fill a prescription for Lybrel written by a non-MTF provider to whom the patient was referred, and 2) MN is established.

COMMITTEE ACTION: The P&T Committee recommended (12 for, 2 opposed, 1 abstained, 2 absent): 1) an effective date of the first Wednesday following a 60-day implementation period in the TMOP and TRRx, and at the MTFs no later than a 60-day implementation period; and 2) TMA send a letter to beneficiaries affected by this UF decision. The implementation period will begin immediately following the approval by the Director, TMA.

6. DRUG CLASS REVIEW – ADRENERGIC BETA-BLOCKING AGENTS (ABAs)

The P&T Committee evaluated the relative clinical effectiveness of the 22 adrenergic beta-blocking agents (ABA) marketed in the US (see Table 1). The ABA drug class was subdivided into three categories; ABAs evaluated (but not necessarily FDA-approved) for treating chronic HF; ABAs not evaluated for HF (older ABAs used primarily for hypertension), and ABA/diuretic combinations (one combination product, timolol/HCTZ

(Timozide) has now been discontinued). The current BCF ABAs are metoprolol tartrate (Lopressor, generics) and atenolol (Tenormin, generics).

The ABAs are all available in generic formulations, with the exception of carvedilol extended/controlled release (Coreg CR), which was introduced to the market in March 2007. Generic formulations of carvedilol IR (Coreg) and metoprolol succinate ER (Toprol XL) were launched in mid- to late-2007.

Table 1 ABAs evaluated by the DoD P&T Committee

Generic	Brand	Generic	Brand
ABAs evaluated for chronic heart failure (but not necessarily FDA-approved)		**Older Adrenergic Blocking Agents not evaluated for chronic heart failure; used primarily for hypertension**	
bisoprolol	Zebeta	acebutolol	Sectral
carvedilol	Coreg CR (controlled release) (GlaxoSmithKline)	atenolol	Tenormin
	Coreg (immediate release)	betaxolol	Kerlone
metoprolol tartrate	Lopressor	labetalol	Trandate (Prometheus) Normodyne (Schering; D/C'd)
metoprolol succinate	Toprol XL (Astra Zeneca)	nadolol	Corgard
ABA/ diuretic combinations		penbutolol	Levatol
atenolol / chlorthalidone	Tenoretic	pindolol	Visken
bisoprolol /HCTZ	Ziac	propranolol	Inderal
metoprolol / HCTZ	Lopressor HCT	propranolol extended release	Inderal LA
nadolol / bendroflumethiazide	Corzide	sotalol	Betapace
propranolol / HCTZ	Inderide	sotalol for atrial fibrillation	Betapace AF
timolol / HCTZ	Timozide (discontinued)	timolol	Blockadren

Expenditures for the ABAs exceeded $140 million in FY 07, ranking them in the top 15 drug class expenditures for the Military Health System (MHS). In terms of 30-day equivalent prescriptions dispensed in FY 07, atenolol (Tenormin, generics) is the highest utilized ABA in the MHS (~225,000/month), followed by branded metoprolol succinate (Toprol XL; ~150,000/month), and metoprolol tartrate (Lopressor, generics; ~100,000/ month). Generic formulations of metoprolol succinate (Toprol XL) have exceeded 50,000 30-day equivalent prescriptions since August 2007. Since market introduction, carvedilol ER (Coreg CR) has seen a steady increase in utilization, which exceeded 12,000 30-day equivalent prescriptions dispensed in October 2007.

A. ABAs – Relative Clinical Effectiveness

The P&T Committee evaluated the relative clinical effectiveness of the ABAs marketed in the U.S. by considering information regarding their safety, effectiveness, and clinical outcomes. The clinical review included consideration of pertinent information from a variety of sources determined by the P&T Committee to be relevant and reliable, including but not limited to sources of information listed in 32 CFR 199.21(e)(1).

The P&T Committee focused on the clinical effectiveness of the ABAs for treating cardiovascular disorders, in particular chronic HF; non-cardiovascular uses were not

evaluated. Use of the ABAs for hypertension and acute MI was only briefly discussed, since all of the older ABAs are available in generic formulations and have been commercially available for decades. Additionally other antihypertensive drug classes are now available that are widely used (e.g., ACE inhibitors, ARBs, calcium channel blockers).

1) *Pharmacology* - With respect to pharmacology, the ABAs differ in their selectivity for the beta (β) and alpha (α) receptors. ABAs with β1-selectivity include atenolol (Tenormin, generics), metoprolol succinate (Toprol XL, generics), metoprolol tartrate (Lopressor, generics) and bisoprolol (Zebeta). Cardioselectivity is postulated to reduce adverse pulmonary effects, however selectivity is dose dependent. Carvedilol (Coreg IR and generics; Coreg CR) and labetolol (Trandate, generics) are non-selective ABAs that have equal affinity for β1 and β2 receptor, and also exhibit α-blocking properties, which decreases peripheral vascular resistance via vasodilation.

2) *FDA-Approved Indications* – All of the ABAs and the ABA/diuretic combinations are approved for treating hypertension, with the exception of sotalol (Betapace, Betapace AF, generics). Both metoprolol tartrate and metoprolol succinate are approved for angina. With regards to chronic HF, carvedilol (Coreg, Coreg CR) and metoprolol succinate are indicated for use to reduce the risk of death; however, there are slight differences in the package labeling. Both Coreg IR and Coreg CR are approved for use in patients with mild to severe HF and to reduce the risk of death following MI in patients with left ventricular systolic dysfunction (LVSD). Metoprolol succinate is approved for treating patients with mild to moderately severe HF. Bisoprolol (Zebeta) is not approved for treating HF, but has evidence of a mortality benefit from one clinical trial (see efficacy section).

3) *Labetolol* – Labetolol is similar to carvedilol in that it is a non-selective ABA that also exhibits α receptor blocking properties. However the Committee agreed that clinical comparisons to carvedilol (Coreg, Coreg CR) would not be considered, since labetolol has not been evaluated in the treatment of chronic HF. Niche uses for labetolol include intravenous use for hypertensive urgency/emergency, and use for pregnancy.

4) *Sotalol* – Unlike the other ABAs, sotalol is the only ABA that is not approved for treating hypertension. Two branded formulations are available; Betapace is FDA-approved for treating ventricular arrhythmias, while Betapace AF is specifically labeled for use in maintaining normal sinus rhythm (NSR) in atrial fibrillation and contains instructions for initiating therapy. The Committee did not further evaluate sotalol, as both Betapace and Betapace AF are available in generic formulations.

5) *Carvedilol ER* – The Committee evaluated the pharmacokinetic and pharmacodynamic differences between carvedilol ER and carvedilol IR. Coreg CR is a capsule containing beads with differing release mechanisms. The Committee agreed that with the exception of the time to max concentration (which is delayed with carvedilol extended release), Coreg CR and carvedilol IR show similar kinetic profiles.

6) *Efficacy for hypertension* – The Oregon Health & Science University's Drug Effectiveness Review Program (DERP) first reviewed the beta blockers in 2005, with an update published in 2007. DERP concluded that the ABAs are equally effective at controlling BP in patients with hypertension. No ABA has been shown to be more efficacious than another, either as initial therapy or when added on to a diuretic, ACE inhibitor or ARB.

7) *Efficacy for chronic HF* – The P&T Committee focused on the use of metoprolol succinate, metoprolol tartrate, carvedilol (Coreg, Coreg CR) and bisoprolol for chronic HF. Both formulations of carvedilol are FDA-approved for HF, but the Coreg CR indication was granted solely based on data from carvedilol IR clinical trials.

   a) *Placebo controlled trials* – Placebo controlled trials conducted with bisoprolol (CIBIS-II, metoprolol succinate (MERIT-HF), and carvedilol IR (US Carvedilol Trial) showed reductions in mortality of approximately 30%. Treatment with carvedilol IR showed a 35% reduction in mortality in patients with severe HF (left ventricular ejection fraction <20%) in the COPERNICUS trial. The CAPRICORN trial supported the use of carvedilol IR as it reduced the risk of death by 23% in post-MI patients with LVSD. FDA-approval for carvedilol ER was based on the clinical trial data with carvedilol IR; Coreg CR has not been evaluated in a clinical trial for HF.

   b) *Head-to-head trials* – Clinical outcomes were evaluated with carvedilol IR vs. metoprolol tartrate in the COMET trial, which enrolled over 3,000 patients with mild to moderate HF. After 58 months, treatment with carvedilol resulted in a significant 17% reduction in mortality and a significant 29% reduction in fatal and non-fatal MI. The superiority of carvedilol over metoprolol tartrate seen in this trial has generated controversy, due to concerns of potential non-equivalent dosage comparisons. Metoprolol succinate was not available to the COMET investigators, and has not been evaluated directly with carvedilol.

   c) *National Guidelines* – The 2005 American College of Cardiology/American Heart Association guidelines specifically mention that three ABAs, metoprolol succinate, carvedilol (Coreg, Coreg CR), and bisoprolol, have shown a benefit in reducing mortality in patient with chronic HF. Patients with Stage C HF should receive one of these three ABAs.

8) *Safety and tolerability* - With respect to safety and tolerability, the adverse event profile of the ABAs is well known, and generally recognized as a class effect. In a retrospective study conducted in 268 patients enrolled in a HF clinic, no difference was seen in the percentage of patients started on either carvedilol IR or metoprolol succinate who were switched to the other drug due to tolerability problems with dizziness, fatigue, or dyspnea.

   With respect to safety differences between carvedilol IR and carvedilol ER, conflicting results have been seen. In one comparative trial in patients with hypertension, the overall incidence of adverse events was lower with carvedilol ER than carvedilol IR. However a higher incidence of adverse events with

carvedilol ER was seen at the 80 mg dose vs. 25 mg carvedilol IR in patients with HF.

9) *Other Factors* – Differences in adherence between carvedilol IR and carvedilol ER were evaluated by the P&T Committee. Carvedilol IR requires twice daily (BID) dosing, while carvedilol ER is dosed once daily (QD), which theoretically should improve patient adherence. Systematic reviews conduced with several drug classes other than the ABAs report adherence rates of 79% +/- 14% with QD dosing, vs. 69% +/- 15% with BID dosing. Whether this increase in adherence translates into improved outcomes for the ABAs used for chronic HF remains unclear.

   One manufacturer-sponsored study evaluating differences in compliance rates between carvedilol ER and carvedilol IR found no difference between the two drugs in 269 patients with HF after 5 months of therapy (Coreg CR: 89.3% +/- 20.8 vs. Coreg: 88.1% +/- 24.1%). The clinical applicability of these results is difficult to determine, due to the open-label design of the Coreg CR arm, and the supervised setting of a HF clinic.

10) *Clinical Coverage* – In order to meet the needs of the majority of patients in DoD, the P&T Committee agreed that an ABA with evidence of a mortality benefit in chronic HF must be included on the BCF. The DoD P&T Committee also agreed that an ABA/diuretic combination need not be included on the BCF.

11) *Therapeutic Interchangeability* – With respect to treating hypertension, the ABAs have a high degree of therapeutic interchangeability. With respect to treating chronic HF, there is a high degree of therapeutic interchangeability between carvedilol, metoprolol succinate, and bisoprolol, which have been shown to reduce mortality.

12) *ABA overall clinical effectiveness conclusion* - The DoD P&T Committee concluded that:

   a) Labetolol was not clinically comparable to carvedilol (Coreg; Coreg CR) despite exhibiting alpha blocking properties, as it has not been evaluated for chronic HF.

   b) Sotalol (Betapace, Betapace AF) was not clinically comparable to the other ABAs, as it is not FDA-approved for treating chronic HF.

   c) For treating hypertension, there is no evidence of clinically relevant differences in efficacy between the ABAs, when titrated to effect.

   d) For treating chronic HF, metoprolol succinate, carvedilol (Coreg, Coreg CR), and bisoprolol have been shown to reduce mortality. Bisoprolol is not FDA-approved for this indication. Based on the available evidence, there is no data to suggest that there are differences in the reduction in mortality between carvedilol, metoprolol succinate, or bisoprolol.

   e) Clinically relevant differences in the safety and tolerability profile of the ABAs are not apparent. There is insufficient evidence to determine if there

are clinically relevant differences in the adverse event profile between carvedilol IR and carvedilol extended release.

f) Despite the convenience of once daily dosing of carvedilol ER, there is no compelling clinical evidence to suggest a benefit of Coreg CR over carvedilol IR.

g) Based on clinical issues alone, there are no compelling reasons to classify any of the ARBs as non-formulary on the UF.

COMMITTEE ACTION: The P&T Committee voted (16 for, 0 opposed, 0 abstained, 1 absent) to accept the conclusions stated above.

B. ABAs – Relative Cost Effectiveness - The P&T Committee evaluated the relative cost effectiveness of the ABAs in relation to efficacy, safety, tolerability, and clinical outcomes of the other agents in the class. Information considered by the P&T Committee included, but was not limited to, sources of information listed in 32 CFR 199.21(e)(2).

For the economic evaluation, the ABAs were functionally divided into three groups, based on predominant use: 1) ABAs for hypertension, 2) ABAs for chronic HF, and 3) ABAs used for other conditions (e.g., severe hypertension; arrhythmias).

The ABAs for hypertension include acebutolol, atenolol, betaxolol, metoprolol tartrate, nadolol, penbutolol, pindolol, propranolol IR and ER, timolol, and their diuretic combinations of atenolol chlorthalidone, bisoprolol/HCTZ, metoprolol tartrate/HCTZ, nadolol/bendroflumethiazide, propranolol/HCTZ, and timolol/HCTZ (which has now been discontinued).

The ABAs for heart failure include bisoprolol, metoprolol succinate, carvedilol IR, and carvedilol ER.

Lastly, the ABA group for other conditions includes sotalol (Betapace, Betapace AF) for ventricular arrhythmias and maintenance of normal science rhythm in patients with atrial fibrillation/flutter and labetolol for hypertension and severe hypertension.

The relative clinical effectiveness evaluation concluded that: 1) for hypertension, ABAs are highly clinically interchangeable when titrated to effect, and 2) for chronic HF, there is insufficient evidence to suggest clinically significant differences between agents [e.g. metoprolol succinate vs. carvedilol (Coreg, Coreg CR) vs. bisoprolol] or between different dosage forms approved for chronic HF (e.g. carvedilol IR vs. carvedilol CR). As a result, CMAs were conducted for each subgroup to compare the relative cost effectiveness of these agents.

Results from the cost effectiveness analyses revealed:

For hypertension,

1) The three most cost effective agents are atenolol, metoprolol tartrate, and propranolol IR, which account for 90% of the hypertensive ABA utilization.

2) The other agents are more costly and have lower utilization relative to the top three, but all of these agents are generically available and are considered to be cost-effective.

For heart failure,

1) Carvedilol IR is the most cost effective ABA followed closely by (ranked from most to least cost effective) bisoprolol, metoprolol succinate, and carvedilol ER.
2) The system-wide weighted average cost per day for carvedilol ER was only slightly higher than that of carvedilol IR, and thus was determined to be cost effective relative to the other ABAs for chronic HF.

For other conditions,

1) Sotalol, sotalol AF, and labetalol are all available in generic formulations and are cost-effective.

A budget impact analysis (BIA) was performed to examine the potential budget impact of a UF scenario with carvedilol ER designated as formulary on the UF versus a one with carvedilol ER designated as non-formulary under the UF. The BIA showed that the scenario that designated carvedilol ER as formulary on the UF resulted in significantly lower MHS expenditures versus the scenario that designated carvedilol ER as non-formulary under the UF.

Cost Effectiveness Conclusion – The P&T Committee concluded for consideration of UF status that:

1) All ABAs used primarily to treat hypertension are cost-effective, with atenolol, metoprolol tartrate, and propranolol IR being the most cost-effective.
2) All of the ABAs with clinical evidence for heart failure are cost-effective, with carvedilol IR being the most effective agent.
3) The ABAs for other indications, sotalol, sotalol AF, and labetalol are cost-effective.

COMMITTEE ACTION: The P&T Committee voted (16 for, 0 opposed, 0 abstained, 1 absent) to accept the cost effectiveness conclusion stated above.

C. ABAs – UF Recommendations

COMMITTEE ACTION – In view of the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of the ABAs, and other relevant factors, the P&T Committee, based upon its collective professional judgment, voted (15 for, 0 opposed, 1 abstained, and 1 absent) to recommend that. atenolol, atenolol-chlorthalidone, metoprolol tartrate, metoprolol succinate, propranolol, propranolol/HCTZ, propranolol ER, timolol, timolol/HCTZ, bisoprolol, bisoprolol/HCTZ, nadolol, nadolol/bendroflumethiazide, acebutolol, betaxolol, penbutolol, carvedilol IR, and carvedilol ER be designated formulary on the UF.

D. ABAs – BCF Review and Recommendations

COMMITTEE ACTION– The P&T Committee considered the BCF status of the ABA agents. Based on the results of the clinical and economic evaluations presented, the P&T Committee voted (15 for, 0 opposed, 1 abstained, and 1 absent) to

recommend that atenolol and metoprolol tartrate be maintained and to add generic formulations of carvedilol IR and metoprolol succinate to the BCF.

7. DRUG CLASS REVIEW – ALPHA BLOCKERS (ABs) FOR BENIGN PROSTATIC HYPERTROPHY (BPH)

A. BPH Alpha Blockers – Relative Clinical Effectiveness

The P&T Committee evaluated the relative clinical effectiveness of the ABs used for BPH that are currently marketed in the US. The BPH ABs comprises the non-uroselective agents terazosin (Hytrin, generics) and (Cardura, Cardura XL, generics), and the uroselective agents alfuzosin (Uroxatral) and tamsulosin (Flomax). The BPH AB class was first reviewed by the DoD P&T Committee in August 2005. Information regarding the safety, effectiveness, and clinical outcomes of these drugs was considered. The clinical review included, but was not limited to, the requirements stated in the UF Rule, 32 CFR 199.21(e)(1). The P&T Committee was advised that there is a statutory presumption that pharmaceutical agents in a therapeutic class are clinically effective and should be included on the UF, unless the P&T Committee finds by a majority vote that a pharmaceutical agent does not have a significant, clinically meaningful therapeutic advantage in terms of safety, effectiveness, or clinical outcome over the other pharmaceutical agents included on the UF in that therapeutic class.

1) *FDA-approved indications* – Terazosin, doxazosin, alfuzosin, and tamsulosin are FDA-approved for treating the signs and symptoms of BPH.

2) *Efficacy measures* - The primary outcome measures used to assess BPH AB efficacy are changes in symptom scores [e.g., American Urological Association Symptom Index (AUA-SI) or international prostate symptom score (IPSS)], and urinary flow rate (Qmax). In clinical trials, a decrease in symptom score of three or more points is generally considered clinically significant, although men self-rate decreases of one to two points as slightly improved symptoms. A change in urinary flow rate of 2 to 3 mL/sec is considered clinically significant.

3) *Efficacy*

   a) *Meta-analyses/systematic reviews* – A meta-analysis [AUA 2003], systematic reviews [Djavan 1999, Clifford & Farmer 2000, Wilt 2002,2003], and pooled analysis concluded that the ABs were effective, and consistently improved lower urinary tract symptoms (LUTS) and Qmax compared to placebo. The ABs produced comparable improvements in LUTS and Qmax.

   b) *Placebo-controlled studies* - Placebo-controlled studies have demonstrated improvements in total symptom score from baseline of about 30% to 50% for the ABs vs. about 10% to 30% for placebo. On average, terazosin reduced AUA-SI score by 3 points; tamsulosin by 3 points [Wilt 2002, 2003]; doxazosin by 3 points at 1 year [Kirby 2003] and 2 points at 4 years, [McConnell 2003]; and alfuzosin by 2 points short-term [MacDonald 2005], more than placebo. Improvements in Qmax for the ABs were about 5% to 15% greater than placebo [Djavan 1999, Clifford & Farmer 2000, Wilt 2002, 2003, Roehrborn 2001].

A rapid response (within 2 weeks) was seen with most ABs. Improvement with tamsulosin has been observed after the first dose, with peak effects occurring after one week [Djavan 1999, 2004]. Alfuzosin has also demonstrated improvement after the first-dose [Djavan 1999, Roehrborn 2001].

c) *Head-to-head trials* - Head-to-head trials and indirect comparative studies (e.g., meta-analysis and systematic reviews) between ABs when used at equivalent doses do not show clinically relevant difference in efficacy, in terms of symptom relief and urodynamic improvements. Overall, for the ABs, total symptom score improved by 30% to 40% relative to baseline and Qmax by 16% to 29%.

d) *Newly published clinical trials* - Since the prior August 2005 DoD P&T Committee review, only two randomized controlled trials and three quality of life (QoL) studies were identified.

- *Nordling 2005* – The first trial was a double-blind, placebo-controlled trial that indirectly compared alfuzosin10 mg or 15 mg or tamsulosin 0.4 mg to placebo. Although alfuzosin and tamsulosin were not directly compared to each other, significant symptoms improvement occurred when both treatments were administered at the recommended doses (i.e., alfuzosin 10 mg, tamsulosin 0.4 mg) compared to placebo. The IPSS change from baseline was similar with both agents.
- *Roehrborn 2006* - The second double-blinded, placebo-controlled study demonstrated that alfuzosin prevented/slowed the overall clinical progression of BPH after 2 years, but did not reduce the risk of acute urinary retention or need for surgery. Alfuzosin reduced AUA-SI score by 1 point, and improved QoL compared to placebo.
- *Elhilali 2006, Flannery 2006, Hartung 2006* - Three non controlled open-labeled studies conducted in the primary care setting suggested that both alfuzosin and tamsulosin improved QoL measures in addition to improving LUTS.
- *Conclusion for new information since 2005* - No newly published U.S. head-to-head trials were identified since the 2005 review was conducted. Review of the clinical literature since 2005 does not add substantial new information or support changes in current clinical practice for the treatment of LUTS in men with BPH.

e) *Efficacy conclusion*- Based on limited head-to-head trials and indirect comparisons between the agents the following conclusions can be made:

- The existing evidence does not support clinically significant differences in efficacy between terazosin, doxazosin, tamsulosin, and alfuzosin.
- All the ABs produce clinically significant symptom improvements when compared to placebo. Results of the AUA meta-analysis suggest terazosin, doxazosin, alfuzosin, and tamsulosin are similar in efficacy, based on partial relief of symptoms and improvement in the AUA-SI Score. Other systematic reviews, meta-analyses, and clinical trials agree with the AUA meta-analysis.

- There are no published head-to-head trials directly comparing alfuzosin with tamsulosin. One trial published since 2005 [Nordling] that indirectly compared alfuzosin or tamsulosin with placebo reported significant symptom improvement with both treatments. Existing evidence does not support clinically significant differences in efficacy between alfuzosin and tamsulosin.

4) *Safety / Tolerability*

a) *Adverse reactions* – The most commonly reported adverse events with the ABs during placebo controlled and open label uncontrolled studies are vasodilatory in nature (e.g., dizziness, asthenia/fatigue, headache, and hypotension). The incidence of vasodilatory effects with alfuzosin and tamsulosin are relatively low. Postural hypotension occurred in approximately 3% of patients treated with tamsulosin and in less than 1% of patients treated with alfuzosin. Asthenia and dizziness were reported in a higher percentage of tamsulosin (7-8%) and alfuzosin (3-4%) treated patients compared to placebo. Adverse events associated with ABs are dose dependent, with a higher incidence reported with higher doses compared to low dose or placebo.

b) *Discontinuation rates* – Discontinuation rates due to adverse events range between 4% to 10% for tamsulosin and alfuzosin, which is comparable to placebo. For terazosin and doxazosin, the percentage of patients who discontinued treatment due to adverse events was 8% to 20%.

c) *Syncope and orthostatic hypotension* **–** The package labeling for all four ABs contain a warning for syncope and orthostatic hypotension; however, these events are more prevalent with terazosin and doxazosin. As a result, terazosin and doxazosin require dose titration when treatment is initiated. In clinical trials, tamsulosin and alfuzosin either do not decrease BP to a clinically significant extent, or reduce BP similar to placebo. Tamsulosin and alfuzosin may be better options for patients with BPH who cannot tolerate a BP reductions, or orthostatic changes in BP, heart rate, or peripheral vascular responsiveness.

d) *Sexual Dysfunction* – The package labeling for tamsulosin carries a warning concerning the risk of priapism. Although alfuzosin labeling does not contain a warning for priapism, post-marketing cases have been reported. Data from the AUA meta-analysis estimated that the rate of ejaculatory dysfunction with tamsulosin was 10%. The incidence of ejaculatory dysfunction with alfuzosin, terazosin, and doxazosin were approximately 1% in placebo-controlled trials.

e) *Drug-drug interactions* – Drug interactions are more of an issue with alfuzosin and tamsulosin compared to doxazosin and terazosin. Alfuzosin is contra-indicated for concomitant use with potent cytochrome P450 (CYP) 3A4 inhibitors such as ketoconazole (Nizoral), itraconazole (Sporanox), and ritonavir (Norvir). Tamsulosin has potential drugs interactions with cimetidine and warfarin.

f) *Drug-drug interactions with phosphodiesterase Type 5 (PDE-5) inhibitors* – PDE-5 inhibitors (sildenafil (Viagra), vardenafil (Levitra), and tadalafil (Cialis)]

are mild vasodilators, which may decrease BP. Concomitant use of PDE-5 inhibitors with any AB may evoke orthostatic hypotension.

g) *Special populations* – Terazosin and doxazosin are rated pregnancy category C, while alfuzosin and tamsulosin are rated pregnancy category B. No AB is indicated for use in women. Doxazosin should be used with caution in patients with hepatic failure. Alfuzosin is contraindicated in patients with moderate or severe hepatic insufficiency (Child-Pugh categories B and C), and caution is recommended in patients with severe renal insufficiency. Alfuzosin should be used with caution in patients with a history of QT prolongation or who are receiving concomitant medications with the potential for QT prolongation. The effect of terazosin, doxazosin, and tamsulosin on the QT interval has not been studied. Allergic reactions with tamsulosin have been reported in patients with sulfa allergy.

h) *Dose titration* – Each time there is a period of noncompliance with terazosin or doxazosin, dosage titration from the lowest dose will be necessary to avoid potential problems with orthostatic hypotension. Dosage titration after non-compliance episodes is not necessary with alfuzosin or terazosin.

i) *Intraoperative Floppy Iris Syndrome (IFIS)* –Tamsulosin can cause a potential intraoperative complication, IFIS, during cataract surgery. IFIS was a recently described phenomenon affecting cataract surgery at the time of the 2005 review. To date, several case reports and observational studies have connected IFIS with tamsulosin use [Blouin 2007, Chang 2005, Chadha 2007, Cheung 2007, Parssinen 2006, Oshika 2007, Takmaz 2007]. The literature has a few anecdotal case reports of IFIS occurring with alfuzosin [Blouin 2007, Settas 2006], terazosin, and doxazosin [Chadha 2007, Parmar 2005]. Data from the FDA) Adverse Event Reporting System (AERS) identified isolated cases suggestive of IFIS with tamsulosin, doxazosin, terazosin, and the 5-alpha reductase inhibitor finasteride (Proscar), and has included this as a precaution in all AB package labeling.

j) *Safety and tolerability conclusion*- Vasodilatory adverse events were reported most commonly with the ABs during placebo-controlled and open label uncontrolled trials. Dizziness and asthenia most commonly lead to discontinuation of therapy. Alfuzosin and tamsulosin appear well-tolerated; there are only a few differences in safety considerations (e.g., drug interactions with CYP3A4 inhibitors; precautions for QT prolongation). Data from the clinical trials published since 2005 did not add substantial new information as to safety, tolerability or adverse events.

5) *Other Factors*

Provider Input: Results from a survey sent to MTF providers indicated that alfuzosin and tamsulosin had similar effectiveness, safety and tolerability profiles.

6) *Therapeutically Interchangeability*

Terazosin and doxazosin the non-uroselective ABs, have a low degree of therapeutic interchangeability with alfuzosin and tamsulosin, the uroselective AB, in terms of

safety/tolerability. The non-uroselective agents have a high incidence of discontinuation rates and vasodilatory effects than the non-uroselective agents.

For the uroselective ABs alfuzosin and tamsulosin, there is a high degree of therapeutic interchangeability with regards to efficacy, safety, and tolerability.

7) Clinical Coverage

Neither alfuzosin nor tamsulosin offers a unique benefit over the other. It is not likely that a patient who did not have an adequate response with one uroselective AB would have a better response with the other. Either alfuzosin or tamsulosin could be expected to meet the needs of the majority of the DoD patients requiring a uroselective agent.

There is no evidence to suggest switching between the four ABs would provide additional benefit to patients who fail treatment due to lack of effectiveness. Patients with an inadequate response to the ABs would be candidates for a 5-alpha reductase inhibitor or surgery. To meet the needs of the majority of the patients in DoD, one non-uroselective AB and one uroselective AB (for patients who can not tolerate a non-uroselective AB) is required.

8) Clinical Effectiveness Conclusion - The P&T Committee concluded that:

a) Based on randomized placebo-controlled trials, terazosin, doxazosin, tamsulosin, and alfuzosin were found to produce clinically significant and comparable symptom improvements when compared to placebo.

b) Based on limited head-to-head trials and indirect comparisons between the agents, existing evidence does not support clinically significant differences in efficacy between alfuzosin and tamsulosin.

c) There appear to be few differences in the incidence of adverse effects with alfuzosin and tamsulosin, based on placebo-controlled trials and limited comparative data. Both agents are well tolerated. The most common adverse events are vasodilatory effects.

d) There appear to be major differences in withdrawal rates due to adverse events between non-uroselective (terazosin and doxazosin) and the uroselective agents (alfuzosin and tamsulosin). Withdrawal rates reported in clinical trials were low overall for alfuzosin and tamsulosin.

e) The package labeling for alfuzosin contains cautions for QT prolongation effects. The effect of tamsulosin on the QT interval has not been studied.

f) Alfuzosin is contraindicated for use with potent CYP3A4 inhibitors such as ketoconazole (Nizoral), itraconazole (Sporanox), and ritonavir (Norvir). Tamsulosin has potential drug interactions with cimetidine and warfarin.

g) Doxazosin should be used with caution in men with hepatic failure. Alfuzosin is contraindicated in men with moderate to severe hepatic impairment (Child-Pugh categories B and C). Tamsulosin does not require dosage adjustment in men with moderate hepatic dysfunction.

h) Package labeling for all four ABs contains information regarding the potential for IFIS. For patients receiving alfuzosin and tamsulosin consultation with an ophthalmologist is recommended prior to cataract surgery.

i) Terazosin and doxazosin have a low degree of therapeutic interchangeability with alfuzosin and tamsulosin in terms of safety/tolerability due to the higher incidence of discontinuation rates and vasodilatory effects seen with the non-uroselective ABs.

j) Alfuzosin and tamsulosin have a high degree of therapeutic interchangeability; either drug could be expected to meet the needs of the majority of DoD BPH patients requiring an uroselective agent.

k) Review of the clinical literature since 2005 does not add substantial new information or support changes in current clinical practice for the treatment of LUTS in men with BPH, or for safety profiles between the uroselective ABs.

l) Based on clinical issues alone, there are no compelling reasons to classify any of the AB agents as non-formulary under the UF.

COMMITTEE ACTION: The P&T Committee voted (16 for, 0 opposed, 0 abstained, 1 absent) to accept the clinical effectiveness conclusions stated above.

B. BPH Alpha Blockers – Relative Cost Effectiveness

The P&T Committee evaluated the relative cost effectiveness of the BPH ABs in relation to efficacy, safety, tolerability, and clinical outcomes of the other agents in the class. Information considered by the P&T Committee included, but was not limited to, sources of information listed in 32 CFR 199.21(e) (2).

The relative clinical effectiveness evaluation concluded that there was insufficient evidence to suggest that the uroselective AB medications differed in regards to efficacy, safety, tolerability, or clinical outcomes data in the treatment of BPH. As a result, a CMA was performed to compare the relative cost effectiveness of potential UF uroselective ABs scenarios. The CMA compared the weighted average cost per day of treatment for each potential UF scenario across all three points of service. The potential UF uroselective ABs scenarios considered were derived from the following condition sets:

1) One selective BPH-AB will be selected to the UF and the BCF. In addition, a PA process would require all new selective BPH-AB users to complete an adequate trial of the UF selective BPH-AB before the non-formulary selective BPH-AB is provided to a new user through an MTF pharmacy, the TMOP, or a TRICARE retail network pharmacy. (1 UF, 1 BCF, with PA)

2) One selective BPH-AB will be selected to the UF and up to one selective BPH-AB will be included on the BCF. (1 UF, 0-1 BCF).

3) Two or more selective BPH-ABs will be selected to the UF and up to one selective BPH-AB will be included on the BCF. (2+ UF, 0-1 BCF)

Results from the AB CMA showed that: 1) UF scenario, under condition set #1, with alfuzosin as the one uroselective agent on the UF and BCF in conjunction with Step

Therapy to be the most cost effective UF scenario considered; 2) UF scenario, under condition set #2, with alfuzosin as the one uroselective agent on the UF and BCF without Step Therapy was the next most cost effective UF scenario considered. However, under this UF scenario, without Step Therapy, the weighted average cost per day of therapy increased by 53% over the most cost effective UF scenario; 3) any condition set that included tamsulosin on the UF was more costly compared to the baseline (what DoD pays today) weighted average cost per day of therapy.

Based on the results of the clinical review and the pharmacoeconomic evaluations, a BIA of various formulary scenarios was conducted to estimate the influence of other factors associated with a UF decision (i.e., market share migration, switch costs, non-formulary cost-shares). The goal of the BIA was to aid the Committee in determining which uroselective AB best met the majority of the clinical needs of the DoD population at the lowest expected cost to the MHS. The results of the BIA paralleled those of the cost effectiveness analysis. The UF scenario, under condition set #1, with alfuzosin as the one uroselective agent on the UF and BCF in conjunction with Step Therapy was the most cost effective UF scenario.

Cost Effectiveness Conclusion – The DoD P&T Committee accepted the conclusions from the cost effectiveness analyses stated above. In addition, the Committee concluded that the UF scenario that maintained alfuzosin as the only uroselective agent on the UF and BCF in conjunction with a step therapy/PA was the most cost effective scenario.

COMMITTEE ACTION: The P&T Committee concluded (16 for, 0 opposed, 0 abstained, and 1 absent) to accept the AB relative CEA as presented by the PEC.

C. BPH Alpha Blockers – UF Recommendations

COMMITTEE ACTION – In view of the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of the ABs, and other relevant factors, the P&T Committee, based upon its collective professional judgment, voted (15 for, 0 opposed, 1 abstained, and 2 absent) to recommend that: 1) alfuzosin be maintained as the uroselective formulary AB, and that terazosin and doxazosin be maintained as the non-uroselective formulary ABs; and 2) tamsulosin be classified as non-formulary under the UF with a PA requiring a trial of alfuzosin for new patients.

D. BPH Alpha Blockers – PA Criteria

The P&T Committee agreed that the following PA criteria should apply to tamsulosin. Coverage would be approved if a patient met any of the following criteria:

1) Automated PA criteria:

    c) The patient has received a prescription for either tamsulosin or alfuzosin at any MHS pharmacy point of service (MTFs, retail network pharmacies, or mail order) during the previous 180 days.

2) PA criteria if automated criteria are not met:

    d) The patient has tried alfuzosin and had an inadequate response or was unable to tolerate treatment due to adverse effects.

e) Treatment with alfuzosin is contraindicated.

The P&T Committee noted that in order for a patient to receive tamsulosin at the formulary cost-share, both the PA and MN criteria must be met. If the PA criteria are met without an approved MN determination, the patient cost-share will be at the non-formulary level. In other words, patients obtaining an approved PA for tamsulosin would NOT automatically receive it at the formulary cost-share.

COMMITTEE ACTION: The P&T Committee voted (15 for, 0 opposed, 1 abstained, 1 absent) to recommend the PA criteria outlined above.

E. BPH Alpha Blockers – MN Criteria

Based on the clinical evaluation for tamsulosin and the conditions for establishing MN for a non-formulary medication provided for in the UF rule, the P&T Committee recommended the following general MN criteria for tamsulosin:

1) The use of formulary alternatives is contraindicated.
2) The patient has experienced significant adverse effects from formulary alternatives.
3) Formulary alternatives have resulted in therapeutic failure.

COMMITTEE ACTION: The P&T Committee voted (15 for, 0 opposed, 1 abstained, 1 absent) to approve the MN criteria outlined above.

F. BPH Alpha Blockers – UF Implementation Period

The P&T Committee recommended an effective date of the first Wednesday following a 60-day implementation period in TMOP program and TRRx, and at the MTFs no later than a 60-day implementation period. The implementation period will begin immediately following approval by the Director, TMA.

MTFs will not be allowed to have tamsulosin on their local formularies. MTFs will be able to fill non-formulary requests for these agents only if both of the following conditions are met: 1) the prescription must be written by a MTF provider; MTFs may (but are not required to) fill a prescription for non-formulary AB agent written by a non-MTF provider to whom the patient was referred, and 2) MN is established.

COMMITTEE ACTION: The P&T Committee recommended (14 for, 1 opposed, 1 abstained, 1 absent) an effective date of the first Wednesday following a 60-day implementation period in the TMOP and TRRx, and at the MTFs no later than a 60-day implementation period. The implementation period will begin immediately following the approval by the Director, TMA.

G. BPH Alpha Blockers – BCF Review and Recommendation

COMMITTEE ACTION: The P&T Committee considered the BCF status of the AB agents. Based on the results of the clinical and economic evaluations presented, the P&T Committee voted (15 for, 0 opposed, 1 abstained, and 1 absent) to recommend that the current BCF listing for this class be maintained, requiring each MTF to carry terazosin and alfuzosin.

8. DRUG CLASS REVIEW – TARGETED IMMUNOMODULATORY BIOLOGICS (TIBs)

A. TIBs – Relative Clinical Effectiveness

The P&T Committee evaluated the relative clinical effectiveness of the TIBs currently marketed in the United States. Information regarding the safety, effectiveness, and clinical outcomes of these drugs was considered. The clinical review included, but was not limited to, the requirements stated in the UF Rule, 32 CFR 199.21(e)(1). The P&T Committee was advised that there is a statutory presumption that pharmaceutical agents in a therapeutic class are clinically effective and should be included on the UF, unless the P&T Committee finds by a majority vote that a pharmaceutical agent does not have a significant, clinically meaningful therapeutic advantage in terms of safety, effectiveness, or clinical outcome over the other pharmaceutical agents included on the UF in that therapeutic class.

The TIB class is comprised of five medications covered as part of the DoD pharmacy benefit: adalimumab (Humira), anakinra (Kineret), etanercept (Enbrel), efalizumab (Raptiva), and alefacept (Amevive). Three similar biologic agents are not part of the pharmacy benefit due to their intravenous (IV) route of administration: abatacept (Orencia), infliximab (Remicade), and rituximab (Rituxan). Like adalimumab and etanercept, infliximab is approved for multiple indications and in many respects directly competes with these two self-administered multiple indication agents. The IV agents were included in the review for comparative purposes only. (See Table 2.)

Table 2. FDA-Approved Indications for Targeted Immunomodulatory Biologics (TIBs)

Brand	Generic	Manufacturer	How Given	RA	JRA	PsA	AS	Plaque psoriasis	Crohn's Disease	UC
Enbrel	etanercept	Amgen/Wyeth	SQ	X	X	X	X	X		
Humira	adalimumab	Abbott	SQ	X	*	X	X	*	X	
Kineret	anakinra	Amgen	SQ	X						
Raptiva	efalizumab	Genentech	SQ					X		
Amevive	alefacept	Astellas	IM/IV					X		
Not part of outpatient pharmacy benefit										
Remicade	infliximab	Centocor	IV	X		X		X	X	X
Orencia	abatacept	BMS	IV	X						
Rituxan**	rituximab	Genentech	IV	X						

RA = rheumatoid arthritis; JRA = juvenile rheumatoid arthritis; PsA = psoriatic arthritis; AS = ankylosing spondylitis; UC = ulcerative colitis; NHL =; SQ = subcutaneous; IM = intramuscular; IV = intravenous
* The Food and Drug Administration is currently considering adalimumab (Humira) for the treatment of JRA and plaque psoriasis.
** Rituxan is also approved for non-Hodgkin's lymphoma.

Since the FDA lacks regulatory authority to approve generic versions of biologic medications, generic formulations for the TIBs are not likely to appear in the near future. The TIB class accounted for approximately $136 million dollars in MHS expenditures in FY 2007, primarily at the retail point of service (66%), followed by MTFs (19%) and mail order (15%). This estimate does not accurately represent utilization of the IV agents (e.g., infliximab), since these medications are commonly administered in clinic or office settings and are included on outpatient pharmacy profiles only in MTFs that choose to maintain such a record. The cost of treatment with these agents is high (on the order of $10,000 to $20,000 annually). There were

approximately 11,500 unique TIB utilizers in the MHS in the most recent quarter (June to August 2007), not including patients receiving IV agents.

The majority of use of TIBs in DoD is for the two multi-indication agents (adalimumab and etanercept), not including patients receiving IV agents. Fewer than 4% of DoD TIB utilizers are receiving other TIBs. Over the entire patient population, adalimumab and etanercept are consistently used in about a 2:1 ratio, although utilization in the last quarter (June to August 2007) shows increased uptake of adalimumab among new users (new users only: 44% use of adalimumab vs. 54% use of etanercept, 2% other TIBs).

1) Pharmacology and Clinical Use

TIBs are used to treat a variety of serious disease states. Based on an analysis of TIB prescriptions for patients with relevant diagnosis codes in the MHS Mart (M2) over a six-month period (January through June 2007), the most commonly treated condition treated with TIBs in DoD is rheumatoid arthritis (RA). About 73% of TIB patients are being treated for RA. Other conditions include psoriasis (15%), psoriatic arthritis (PsA) (7%), ankylosing spondylitis (AS) (4%), as well as Crohn's disease, juvenile rheumatoid arthritis (JRA), and ulcerative colitis (UC) (all less than 1% each). In most cases the TIBs are indicated as treatment for moderate to severe cases of these conditions, usually following an inadequate response to initial therapy.

Table 3. Dosing and Administration of the TIBs

Brand	Generic	Dosing
Enbrel	etanercept	**RA, PsA, AS** – 25 mg twice weekly or 50 mg once weekly SQ **JRA** (4-17 years) – 0.8 mg/kg per week (maximum 50 mg per week), given once or twice per week SQ **Plaque psoriasis** – 50 mg twice weekly SQ for 3 months, then decrease to 50 mg SQ weekly
Humira	adalimumab	**RA** – 40 mg every other week SQ, may increase to 40 mg q week for monotherapy **PsA, AS** – 40 mg every other week SQ **Crohn's** – 160 mg at week 0, 80 mg at week 2, then 40 mg every other week beginning week 4
Kineret	anakinra	**RA** – 100 mg daily SQ (consider 100 mg every other day SQ in patients with severe renal insufficiency or end stage renal disease)
Raptiva	efalizumab	**Plaque psoriasis** – Initial 0.7 mg/kg SQ injection, then 1 mg/kg weekly SQ injections (not to exceed 200 mg)
Amevive	alefacept	**Plaque psoriasis** – 15 mg once weekly IM; continue for 12 weeks; after a 12-week interval, may retreat with an additional 12-week course if CD4+ T lymphocyte counts are >250 cells/μL
Not part of outpatient pharmacy benefit		
Remicade	infliximab	**RA (adult)** – 3 mg/kg IV infusion at 0, 2, 6 weeks, then every 8 weeks (may increase to maximum of 10 mg/kg every 4 weeks) **RA (pediatric; 6-17 years)** – 5 mg/kg IV infusion at 0, 2, 6 weeks, then every 8 weeks **Crohn's** – 5 mg/kg IV infusion at 0, 2, 6 weeks, then every 8 weeks (may increase to 10 mg/kg) **PsA -** 5 mg/kg IV infusion at 0, 2, 6 weeks, then every 8 weeks **AS** – 5 mg/kg IV infusion at 0, 2, 6 weeks, then every 6 weeks **UC, plaque psoriasis** – 5 mg/kg IV infusion at 0, 2, 6 weeks, then every 8 weeks Doses > 5 mg/kg per day are contraindicated in patients with moderate to severe heart failure.
Orencia	abatacept	**RA** – IV based on body weight <60 kg = 500 mg; 60-100 kg = 750 mg; >100 kg = 1000 mg); initial dose at 0, 2, 4 weeks, then every 4 weeks
Rituxan	rituximab	**RA** – 1000 mg IV infusion on days 1 and 15 in combination with methotrexate. Safety and efficacy of retreatment not established.

RA = rheumatoid arthritis; JRA = juvenile rheumatoid arthritis; PsA = psoriatic arthritis; AS = ankylosing spondylitis; UC = ulcerative colitis; NHL =; SQ = subcutaneous; IM = intramuscular; IV = intravenous

The TIBs target various mediators of the inflammation cascade, effectively retarding the extent and severity of inflammation at the local level. Etanercept,

adalimumab, and infliximab all act through inhibition of tumor necrosis factor-alpha (TNF-α). Adalimumab and infliximab are monoclonal antibodies; they bind specifically to TNF-α, blocking interaction with the p55 and p75 cell surface TNF receptors. Etanercept is a soluble receptor to TNF- α that binds circulating TNF-α and lymphotoxin-α, preventing interaction with cell surface receptors. Anakinra (which is FDA-indicated only for RA) is a human recombinant protein that competitively blocks the interleukin (IL)-1 receptor, blocking inflammatory and immunological responses.

The other TIBs affect T cell (alefacept, efalizumab, abatacept) or B cell (rituximab) involvement in autoimmune and inflammatory processes. Alefacept and efalizumab are FDA-indicated only for the treatment of plaque psoriasis, while the IV agents abatacept and rituximab are FDA-indicated only for RA.

Dosing of the various agents varies from every 8 weeks via IV infusion (infliximab) to daily subcutaneous dosing (anakinra) (See Table 3).

The two multi-indication self-administered TIBs, adalimumab and etanercept, are given every 1 or 2 weeks (see Table 2). Major areas of uncertainty about actual dosing of the TIBs (which may affect safety, tolerability, and efficacy as well as cost) are: 1) the percent of RA patients who receive weekly rather than every other week dosing with adalimumab; 2) the percent of plaque psoriasis patients who continue to receive twice weekly dosing with etanercept 50 mg following the 12-week induction phase; and 3) the percent of patients who receive higher or more frequent doses of infliximab for the treatment of RA and Crohn's disease.

2) Efficacy

A recent well-done systematic review of the drugs in this class is available from the Oregon Health & Science University's DERP. The January 2007 review included published clinical trials through August 2006. The review took a "best evidence" approach, with a primary focus on health outcomes (symptoms, QoL, functional capacity, hospitalizations, and mortality). Radiological changes were considered as a secondary, intermediate measure.

Many TIB trials, particularly in rheumatologic conditions, included treatment with disease-modifying antirheumatic drugs (DMARDs), particularly methotrexate (MTX), either as monotherapy or in combination with a TIB. (Although the term DMARD technically includes the TIBs, which slow disease progression in RA, it is used in this evaluation to refer solely to non-biologic agents that slow disease progression in RA, such as MTX, sulfasalazine, gold salts, and hydroxylchloroquine.) Since there are no head-to-head RCTs comparing two or more TIBs, comparisons between TIBs in any given disease state primarily rest on the results of placebo- and/or active-controlled RCTs.

As part of its evaluation of the TIB class, the P&T Committee considered summary efficacy and safety data and conclusions from the DERP review, along with more recently published clinical data following the same general approach. Unpublished data provided by pharmaceutical manufacturers as part of their Academy of Managed Care Pharmacy "dossiers" were also considered when little

published data were available (published trials have undergone peer review and are generally considered more reliable than unpublished data). Additional information (typically from open label extension trials or observational studies) was also considered to address questions concerning switching between the TIBs (e.g., in patients refractory to treatment), long-term efficacy and safety, and effects on QoL and productivity.

Few published guidelines to date attempt to establish the place of specific TIBs in the treatment of the disease states addressed in this evaluation.

a) Rheumatoid Arthritis

A prominent RA efficacy measure is the number of patients attaining a American College of Rheumatology (ACR) 20, 50 , or 70 response, based on at least a 20, 50, or 70% reduction compared to baseline in tender / swollen joint counts plus improvements in at least three other specified measures of pain, overall effect, or laboratory measures of inflammation. DERP reviewers chose an ACR 50 response as the outcome measure for adjusted indirect comparisons of randomized placebo controlled trials because it was felt to translate to a clinically significant improvement in health-related QoL.

Based both on trials included in the DERP review and more recently published trials, there is good-to-fair evidence from meta-analyses and large placebo-controlled RCTs supporting the efficacy of etanercept, adalimumab, and anakinra for the treatment of RA. The same is true for the IV agents infliximab, abatacept, and rituximab. Alefacept and efalizumab lack evidence for the treatment of RA. In general, combination treatment with TIBs plus MTX offered better efficacy than TIBs or MTX alone. The same was true of the DMARD sulfasalazine based on one trial. Beneficial effects on QoL and productivity were associated with improvements in clinical response.

Meta-analysis results from the DERP review suggested no significant difference in efficacy among etanercept, adalimumab, and infliximab for the treatment of RA. Point estimates favored the TNF inhibitors (etanercept, adalimumab, and infliximab) over the IL-1 inhibitor anakinra, although differences were statistically significant only for ACR 20 and not ACR 50 response. A recent high-quality meta-analysis [Nixon et al, 2007] similarly reported comparable efficacy among etanercept, adalimumab, and infliximab for the treatment of RA. An analysis comparing anakinra to the TNF inhibitors as a class concluded that the TNF inhibitors were statistically significantly more efficacious than anakinra (OR 1.96, 95% CI 1.03 to 4.01 for ACR 20; OR 1.93, 95% CI of 1.05 to 3.50 for ACR 50).

Numerous studies have shown clinical benefit in patients switching from one TIB to another, including patients switching from infliximab to etanercept, etanercept to infliximab, etanercept to adalimumab, infliximab to adalimumab, and TNF inhibitors to rituximab or abatacept. In general, clinical response was seen with the second TIB regardless of the reason for switching—albeit at lower rates than in TIB-naïve patients—with no increase in adverse events. This appeared to be true both for switches between TNF

inhibitors and from a TNF inhibitor to another TIB. Data on the efficacy of switching to a third TNF inhibitor are mixed.

Another important aspect of overall efficacy concerns the impact of TIBs and other DMARDs on delaying the progressive structural destruction of peripheral joints seen in RA. A common measure is the Total Sharp Score (TSS), which is based on evaluation of x-rays of hands and feet scored for joint erosions and joint space narrowing. Optimally, treatment would both control RA symptoms and delay (or even halt) radiographic disease progression.

Long-term data supporting maintenance of effects on clinical measures (e.g., ACR response) is available for all the TIBs used for the treatment of RA; however, the length of follow-up varies. The longest-term data are available for adalimumab and etanercept (4 to 7 years). Both of these TIBs have evidence supporting delay in radiographic progression for up to 2 years. Infliximab and abatacept have 1-year data supporting sustained effects on clinical measures and radiographic progression. Anakinra has data supporting sustained effects on clinical measures for up to 1 year, but radiographic data only out to 6 months; rituximab lacks radiographic data but has data supporting sustained effect on clinical measures for up to 2 years (following one course of therapy).

b) Juvenile Rheumatoid Arthritis

Etanercept is the only TIB with published evidence that demonstrates efficacy for the treatment of JRA and the only TIB indicated for this condition. Evidence is limited to a single placebo-controlled RCT; similar results are reported in a retrospective analysis of registry data from Germany in pediatric patients with various forms of arthritis. A small, uncontrolled open-label study provides insufficient evidence for infliximab.

Unpublished evidence suggesting efficacy for adalimumab in JRA is available from the manufacturer; FDA approval of adalimumab for this indication is pending.

There is some uncontrolled or observational evidence with infliximab, etanercept, and adalimumab for the treatment of JRA-associated uveitis.

c) Ankylosing Spondylitis

AS causes inflammation of the spine and large joints, resulting in stiffness and pain and often progressive disability. Clinical measures are based on improvement in symptoms such as pain, morning stiffness, fatigue, and mobility. Non-biologic DMARDs are not consistently helpful for the treatment of AS.

Based both on trials included in the DERP review and more recently published trials, sufficient evidence exists to support efficacy of adalimumab, etanercept, and infliximab for treatment of AS symptoms over a period of one to three years, compared to placebo. It is not known if long-term treatment with TNF inhibitors or other biologics can alter the progression of AS. There

is insufficient evidence to conclude that there are differences in comparative efficacy.

One trial provided evidence of successful switching from infliximab to etanercept in patients with loss of efficacy or adverse events on infliximab. There are insufficient data to generalize these results across all treatments.

d) Psoriatic Arthritis

PsA is a chronic inflammatory arthritis associated with psoriasis. Approximately 10 to 30% of psoriasis patients will develop PsA; the psoriasis usually predates the arthritis by many years. Many RA measures are also used in PsA.

Based both on trials included in the DERP review and more recently published trials, evidence from seven placebo-controlled trials supports efficacy of etanercept (two trials), infliximab (two trials), and adalimumab (three trials) in the treatment of PsA. There is insufficient evidence to conclude that there are differences in comparative efficacy among these three agents. A high-quality meta-analysis of placebo-controlled trials [Woolacott et al, 2007] showed very similar treatment effects between etanercept and infliximab.

Long-term data out to 2 years is available for all three agents, including evidence supporting sustained effects on clinical measures of response and radiographic progression.

One trial with efalizumab (which is FDA indicated only for the treatment of plaque psoriasis) reported negative results in PsA. No statistically significant difference in ACR 20 response was seen at 12 weeks, compared to placebo.

e) Plaque Psoriasis

In psoriasis, an environmental trigger is thought to evoke an inflammatory response and subsequent hyperproliferation of keratinocytes, associated with activation of T cells which migrate from the vasculature into the dermal tissues.

A prominent clinical measure of disease severity is the Psoriasis Area and Severity Index (PASI), which incorporates measures of scaling, erythema, and induration of the head, trunk, upper and lower limbs, weighted by severity and affected body surface area. PASI 50/75/90/100 scores represent improvements from baseline in PASI score and are typically reported as the percentages of patients achieving a certain PASI improvement. A PASI 75 response is considered to be the benchmark for current therapies, particularly the biologics.

Based both on trials included in the DERP review and more recently published trials, evidence from published placebo-controlled RCTs supports efficacy of adalimumab (one trial), alefacept (two trials), efalizumab (four trials), etanercept (four trials), and infliximab (three trials) in the treatment of plaque psoriasis.

Due to lack of direct comparative data, it is difficult to draw conclusions regarding comparative efficacy. However, PASI 75 response rates appear consistently higher for infliximab compared to the other TIBs used for the treatment of plaque psoriasis, although some evidence suggests diminishing effect with infliximab as continuous use approaches 1 year. PASI 75 response rates for alefacept, efalizumab, and etanercept appear similar in 12- to 24-week trials.

Evidence for adalimumab in psoriasis includes one published RCT [Gordon et al, 2006] and additional unpublished data available from the manufacturer. FDA approval of adalimumab for plaque psoriasis is pending.

f) Crohn's Disease

Crohn's disease is a chronic inflammatory disease primarily involving the small and large intestine. In its most severe form, it can be associated with the development of deep ulcers and fistulas that can penetrate into adjoining structures or even to the surface skin, leading to infection. The spread of inflammation and thickening of the bowel wall can lead to bowel obstruction. Symptoms may include diarrhea, abdominal pain, anemia, and weight loss. Treatments include 5-aminosalicylic acid, antibiotics, corticosteroids (for patients without fistulas or abscesses), metronidazole (fistulizing disease), immunosuppressives, methotrexate, and TIBs.

Based both on trials included in the DERP review and more recently published trials, there is fair to good evidence from placebo-controlled RCTs supporting efficacy of infliximab (seven trials) and adalimumab (four trials) for initial and maintenance treatment of Crohn's disease.

There is insufficient evidence to conclude that there are differences in comparative efficacy between infliximab and adalimumab for the treatment of Crohn's disease. Both biologics have published data demonstrating persistence of response for up to one year.

One difference is use in children. Infliximab, but not adalimumab, has published evidence and is indicated for the treatment of pediatric Crohn's disease (ages 6 to 17 years).

Etanercept does not appear to be efficacious for Crohn's disease based on one fair-quality placebo-controlled trial [Sandborn et al, 2001]. The manufacturer states that they have discontinued development of etanercept for this indication. The difference in effect compared to the other two TNF inhibitors may be due to mechanistic differences between the monoclonal antibody agents (adalimumab and infliximab) and the soluble receptor agent etanercept.

g) Ulcerative Colitis

UC is a chronic inflammatory and ulcerative disease arising in the colonic mucosa, characterized most often by bloody diarrhea; fistulas and abscesses do not occur. Treatment includes 5-aminosalicylic acid (enemas or oral), corticosteroids, immunosuppressives (azathioprine), and TIBs.

Infliximab is the only TIB currently FDA-indicated for UC, with evidence from three published placebo-controlled RCTs supporting efficacy. No published RCTs were found for other TIBs in the treatment of UC.

3) Safety and Tolerability

a) Overall Adverse Event Profile

Overall, TIBs were well-tolerated during clinical trials; the most common and consistently reported adverse events (AEs) are injection site or infusion reactions (depending on route). With the exception of injection reactions, the overall rate of AEs and the percentage of patients discontinuing treatment due to AEs (3-16%) were typically comparable to placebo. The incidence of AEs does not appear to increase over time.

Anakinra may cause more injection reactions than adalimumab and etanercept based on the mean crude incidence of injection reactions calculated by DERP reviewers from clinical trials included in that review: 17.5% for adalimumab (95% CI 7.1-27.9); 22.4% for etanercept (95% CI 8.5-36.3); but 67.2% for anakinra (95% CI 38.7-95.7).

Infusion reactions have the potential to be more serious than injection site reactions; severe acute reactions have been reported in a small percentage of patients (~1%) after infliximab infusions.

b) Rare but Serious Adverse Events

The primary safety concerns with TIBs are related to the potential for increased risk of serious AEs (e.g., infections, malignancies, autoimmune disorders, etc), most of which are associated with the drugs' effects on the immune system. These effects are rare and cannot be assessed reliably during clinical trials, although the overall incidence of serious AEs tends to be higher with TIBs compared to placebo, and trends in large RCTs approach statistical significance. Current evidence focusing on specific serious adverse events is primarily observational.

Black box warnings concerning the risk of serious infections and the need to test for latent tuberculosis (TB) prior to initiating TIB therapy are included in labeling for adalimumab and infliximab; similar information appears in labeling for other TIBs. In general, caution is indicated in patients with chronic infections or a history of recurrent infections, and TIBs should be stopped if the patient develops a serious infection.

Other black box warnings for TIBs include the risk of hepatosplenic T-cell lymphoma with infliximab (reported in young Crohn's disease patients on other immunomodulatory medications) and a list of potentially severe reactions primarily associated with the use of rituximab for conditions other than RA. There are relatively few absolute contraindications for the TIBs. Alefacept is contraindicated in patients with HIV; etanercept is contraindicated in sepsis; and doses of infliximab greater than 5 mg/kg are contraindicated in patients with moderate to severe heart failure.

(i) Serious Infections

The most common serious infection appears to be TB. Observational studies have also reported infections with coccidiomycosis, histoplasmosis, pneumocystis carinii, listeriosis, candida, and Legionella. Evidence from RCTs is limited.

- A meta-analysis [Bongartz et al, 2006] that pooled data from adalimumab and infliximab RA trials (total n >5000) reported a pooled odds ratio for serious infections of 2.0 (95% CI 1.3 to 3.1), with a number needed to harm of 59 (95% CI 39 to 125) over 3 to 12 months.
- A large RCT (n=1084) designed to assess the risk of serious infections with infliximab in RA patients [Westhovens et al, 2006] reported similar rates of serious infections in patients treated with 3 mg/kg infliximab vs. placebo (RR: 1.0; 95% CI 0.3 to 3.1). However, patients treated with 10mg/kg infliximab had a significantly higher rate of serious infections vs. placebo (RR: 3.1 95% CI 1.2 to 7.9).

The DERP review also included five retrospective database analyses and a prospective cohort study that in general supported a higher risk of TB or granulomatous infection in patients treated with etanercept or infliximab compared to unexposed patients; more recently published studies do not add substantial evidence.

When all data are considered, the P&T Committee agreed that there is fair evidence of an increased risk of serious infections (including TB) for TIBs compared to placebo. There is insufficient evidence to draw conclusions about the comparative risk of serious infection.

(ii) Malignancies

The P&T Committee agreed that largely observational evidence indicates a higher risk of lymphoma for patients treated with infliximab or etanercept. Results of studies addressing other malignancies are mixed. There is insufficient evidence to draw conclusions about comparative risk.

(iii)Chronic Heart Failure

Evidence concerning the safety of TIBs in patients with chronic heart HF and the effects of TIBs on the development of chronic HF is mixed. Data from two unpublished etanercept RCTs and one published infliximab RCT evaluating these TIBs for the *treatment* of chronic HF suggested higher rates of mortality among chronic HF patients treated with etanercept or infliximab, compared to placebo. However, observational studies have reported *lower* rates of cardiovascular events in RA patients receiving TNF inhibitors compared to those receiving conventional therapy. Caution is indicated.

(iv) Other

All TNF inhibitors appear to cause the development of autoantibodies to some extent. Cases of drug-induced lupus, lupus-like syndromes and

other autoimmune disorders have been reported with etanercept, adalimumab, and infliximab. The relationship among auto-antibody levels, the likelihood of infusion reactions, degree and durability of clinical response, and the development of autoimmune disorders is unclear.

Based on case reports and product labeling, adalimumab, etanercept, and Infliximab may be associated with demyelination. Hepatotoxicity has been reported with infliximab and alefacept. Potential effects on hematologic parameters requiring laboratory monitoring include neutropenia with anakinra (neutrophil counts monthly for 3 months, then quarterly for 1 year); dose-dependent reductions in CD4+ T lymphocytes reported with alefacept (CD4+ T lymphocyte counts every 2 weeks during the 12-week treatment period); and periodic assessment of platelet counts with efalizumab (monthly to quarterly).

c) Drug Interactions

There is little substantive information concerning potential drug interactions with the TIBs. They are in general considered safe for use with the large number of drugs used concomitantly in clinical trials.

In general, additive effects on the immune system appear to preclude concomitant treatment with more than one TIB. A trial assessing a combination of anakinra and etanercept (plus MTX) appeared to offer no additional clinical benefit compared to etanercept plus MTX, but resulted in a substantially higher rate of pancytopenia and serious infections. Similarly, a trial assessing the addition of abatacept to etanercept appeared to offer minimal additional clinical benefit compared to etanercept alone, but resulted in a substantially higher rate of adverse events (including serious adverse events and serious infections).

4) Use in Special Populations

Overall, TIBs do not appear to have major differences in terms of efficacy or safety/tolerability in specific subsets of patients (e.g., based on age, gender, race, or comorbid conditions), although this has not been extensively studied. A higher risk of mortality among chronic HF patients treated with etanercept or infliximab has been previously discussed. Caution is in general indicated in elderly patients due to a higher background risk for serious infections and malignancy.

Other differences include varying pregnancy categories (B vs. C) across drugs (alefacept, abatacept, and rituximab are Category C due either to complete lack of data or some evidence of harm in animal studies); the potential for a higher risk of AEs with anakinra in patients with impaired renal function (anakinra is known to be substantially excreted by the kidney; dose reduction is recommended); and the availability of safety and efficacy data in pediatric patients (etanercept is the only TIB FDA-indicated for JRA; infliximab is the only TIB indicated for pediatric Crohn's disease [age 6-17]).

5) Provider Opinion

Opinions of MTF providers familiar with the use of TIBs were solicited through the Army, Navy, and Air Force specialty leaders for the three specialties in which these agents are primarily used (rheumatology, dermatology, and gastroenterology).

- *Rheumatology* – Factors influencing the decision to choose between adalimumab and etanercept were frequency of dosing and the shorter half-life of etanercept, which was considered useful in patients in whom there was a fear of infectious complications. Responders considered the two equally efficacious, and almost universally reported efficacy with a second TIB in patients who had had an inadequate response to the first TIB. They tended to use abatacept, then rituximab, in patients failing TNF agents, usually after a trial of two agents. Anakinra was not considered useful in RA; responders cited anecdotal use in Still's disease (pediatric and adult).
- *Dermatology* – Responders stated that they usually started with etanercept for psoriasis (with which they had the most experience) or adalimumab; many would consider adalimumab after a 4- to 6-month trial of etanercept. Some do use adalimumab as first line. Based on the published data (PASI 75 scores), providers thought that adalimumab might have greater efficacy, although they also theorized that it might have a higher risk of infection based on its binding of both tissue-bound and soluble TNF. Comments about dosing of etanercept (i.e., patients staying on the twice-weekly 50 mg dose after the initial treatment period) included a perception that many patients require the higher dose and that many also require additional therapy (phototherapy, MTX), the possibility that etanercept may need to be weight-based due to higher TNF production in patients with a high BMI; and the perception that effects of etanercept may wane over time, requiring that the dose be increased back to 50 mg twice weekly.

  Survey responders typically placed efalizumab before alefacept in patients with a contraindication to TNF inhibitors or who had failed etanercept or adalimumab. Efalizumab was noted to be helpful when treating very heavy or light-weight individuals, since dosing is weight-based; it was also noted as having a potential role in some off-label uses. Infliximab was typically reserved for severe or refractory disease or for patients in whom a more rapid onset of improvement is necessary (pustular psoriasis); responders noted that cyclosporine and infliximab are really the only options for acute cases.
- *Gastroenterology* – Responders commented that most are now using adalimumab for Crohn's disease to some extent (instead of infliximab); some prefer adalimumab as the first choice because of easier administration. They perceived that many providers will continue to use infliximab due to lack of guidelines. They noted that the factors affecting their choice of biologic agent for Crohn's disease were concerns about infusion reactions, antibody formation, need for a concomitant immunosuppressant, and type of disease

(with more literature and experience with infliximab for the treatment of fistulizing disease).

Responders did not perceive that there was much (off-label) use of adalimumab for Crohn's disease at present, although some providers have commented that they would try it before cyclosporine or colectomy in patients who cannot take infliximab.

Relative Clinical Effectiveness Conclusion: The P&T Committee voted (16 for, 0 opposed, 0 abstained, 1 absent) to accept the following clinical effectiveness conclusion:

a) Across all disease states reviewed, all of the TIBs FDA-indicated for a particular condition have sufficient evidence from placebo-controlled RCTs to demonstrate efficacy. TIBs are typically added to standard therapy in patients with moderate to severe disease. In general, combination treatment of rheumatologic conditions with TIBs plus MTX offers better efficacy than TIBs or MTX alone. Beneficial effects on QoL and productivity are associated with improvements in clinical response.

b) There is a lack of direct comparative evidence (head-to-head RCTs) across all disease states. In all disease states except RA, trials were too small in number or too heterogeneous to make indirect comparisons based on meta-analysis of placebo-controlled trials feasible. With two exceptions, treatment effect across agents appeared similar.

c) In RA, anakinra appears to be less efficacious than the TNF inhibitors (etanercept, adalimumab, and infliximab) with respect to effects on symptoms (ACR response), based on indirect comparison of data from placebo-controlled trials.

d) In psoriasis, PASI 75 scores for infliximab appeared consistently higher than with other TIBs used for psoriasis (etanercept, alefacept, and efalizumab), although there is insufficient comparative evidence to draw a definitive conclusion. Some evidence suggests diminishing effect with infliximab as continuous use approaches 1 year. PASI 75 response rates for alefacept, efalizumab, and etanercept appear similar in 12- to 24-week trials. An indication for adalimumab for the treatment of plaque psoriasis is under consideration by the FDA; one published trial and additional unpublished data available from the manufacturer supports its efficacy for this condition.

e) The multi-indication self-administered TIBs (adalimumab and etanercept) compare favorably to one another. Etanercept did not appear to be efficacious in Crohn's disease, for which adalimumab is indicated. Adalimumab lacks published evidence in JRA and has limited published evidence in psoriasis; however, the manufacturer has unpublished data suggesting efficacy in both disease states and both are under consideration by the FDA. For disease states in which both are indicated, there is little evidence to suggest any clinically relevant difference in treatment effect.

f) Alefacept and efalizumab are FDA-indicated only for psoriasis; they appear to compare favorably to etanercept in terms of treatment effect. Their place in therapy relative to etanercept and infliximab (and potentially adalimumab) in the treatment of psoriasis is probably dependent on factors such as intramuscular administration of alefacept, recommended lab monitoring with both agents, and greater familiarity of providers with the TNF inhibitors.

g) Overall, TIBs were well-tolerated during clinical trials; the most common and consistently reported AEs are injection site or infusion reactions (depending on route). Anakinra may cause more injection reactions than adalimumab and etanercept based on the mean crude incidence of injection reactions calculated by DERP reviewers from clinical trials included in that review: 17.5% for adalimumab (95% CI 7.1-27.9); 22.4% for etanercept (95% CI 8.5-36.3); but 67.2% for anakinra (95% CI 38.7-95.7). In addition, anakinra is given once daily, as opposed to weekly or every other week dosing for adalimumab and etanercept.

h) The primary safety concerns with TIBs are related to the potential for increased risk of serious AEs (e.g., infections, malignancies, autoimmune disorders, etc), most of which are associated with the drugs' effects on the immune system. These effects are rare and cannot be assessed reliably during clinical trials, although the overall incidence of serious AEs tends to be higher with TIBs compared to placebo, and trends in large RCTs approach statistical significance. There is insufficient evidence to draw conclusions about comparative risk of any of these serious AEs.

   i) There is fair evidence of an increased risk of serious infections (including TB) for TIBs compared to placebo.

   ii) Observational evidence indicates a higher risk of lymphoma for patients treated with infliximab or etanercept. Results of studies addressing other malignancies are mixed.

   iii) Evidence concerning the safety of TIBs in patients with chronic HF and the effects of TIBs on the development of chronic HF is mixed. Data from etanercept and infliximab RCTs evaluating these TIBs for the *treatment* of chronic HF suggested higher rates of mortality compared to placebo. However, observational studies have reported *lower* rates of cardio-vascular events in RA patients on TNF inhibitors compared to those on conventional therapy.

   iv) All TNF inhibitors appear to cause the development of autoantibodies to some extent. Cases of drug-induced lupus, lupus-like syndromes and other autoimmune disorders have been reported with etanercept, adalimumab, and infliximab.

   v) Adalimumab, etanercept, and infliximab may be associated with demyelination. Hepatotoxicity has been reported with infliximab and alefacept.

vi) Laboratory monitoring is required or recommended for anakinra (neutrophil counts), alefacept (CD4+ T lymphocyte counts), and efalizumab (platelet counts) due to reports of hematologic abnormalities.

i) There is little substantive information concerning potential drug interactions with the TIBs, which are in general considered safe for use with the large number of drugs used concomitantly in clinical trials. Based on two combination trials (one with anakinra plus etanercept and one with abatacept plus etanercept), additive effects on the immune system appear to preclude concomitant treatment with more than one TIB.

j) Overall, TIBs do not appear to have major differences in terms of efficacy or safety/tolerability in specific subsets of patients (e.g., based on age, gender, race, or comorbid conditions), with the exception of a reported higher risk of mortality among chronic HF patients treated with etanercept or infliximab. Potential differences include varying pregnancy categories (B vs. C) across drugs (alefacept, abatacept, and rituximab are Category C); the need for dose reduction of anakinra in patients with impaired renal function; and availability of data in pediatric patients (etanercept for JRA; infliximab for pediatric Crohn's disease).

B. TIBs – Relative Cost Effectiveness –The P&T Committee evaluated the relative cost effectiveness of the TIBs in relation to efficacy, safety, tolerability, and clinical outcomes of the other agents in the class. Information considered by the P&T Committee included, but was not limited to, sources of information listed in 32 CFR 199.21(e)(2).

The TIBs were grouped into sub-groups according to the number of indications for treatment that each agent possessed. The multi-indication agents included etanercept and adalimumab, and the single-indication agents consisted of anakinra, efalizumab, and alefacept. The cost effectiveness review compared the estimated cost of treatment by disease state for RA and plaque psoriasis. For RA, the analysis compared etanercept, adalimumab, anakinra, and infliximab, while the analysis of plaque psoriasis compared efalizumab, etanercept, and alefacept. Although infliximab is not part of the pharmacy benefit (it is covered under the TRICARE medical benefit), it was included in the analysis because it has indications for treatment that are similar to the products evaluated for the TIBs cost effectiveness review.

The relative clinical effectiveness evaluation concluded that the TIBs are effective for the treatment of RA and plaque psoriasis. Moreover, there was insufficient evidence to suggest that the TIBs' treatment effectiveness differed for RA and plaque psoriasis with one exception: Anakinra appeared to be less effective for the treatment of RA than the multi-indication TIBs, based on the available evidence.

With this information, a cost analysis for RA was conducted to compare the expected cost per year of treatment for each drug product by indication across all three points of service. Results from the analysis showed that adalimumab was the most cost effective TIB for treatment of RA. Etanercept was more costly than adalimumab with similar clinical effectiveness, while anakinra was the most costly agent evaluated and

was less effective than the multi-indication TIBs. The results showed that neither etanercept nor anakinra were cost effective when compared to adalimumab for the treatment of RA, and the conclusions were robust to assumptions about dose escalation with adalimumab. In the analysis of plaque psoriasis, all three products evaluated had comparable cost effectiveness profiles.

Based on the results of the clinical review and the pharmacoeconomic evaluations, a BIA of various formulary scenarios was conducted to estimate the influence of other factors associated with a UF decision (i.e., condition sets, market share migration, switch costs, non-formulary cost shares). The goal of the BIA was to aid the Committee in determining which group of multi-indication TIBs best met the majority of the clinical needs of the DOD population at the lowest expected cost to the MHS. The results showed that the scenario where adalimumab was the sole multi-indication TIB on the UF was the most cost effective scenario evaluated in the BIA.

Cost Effectiveness Conclusion – The P&T Committee concluded that:

1) For RA, the clinical effectiveness evaluation concluded that anakinra appears to be less effective for the treatment of RA than the multi-indication TIBs. A cost effectiveness analysis comparing the expected cost per year of treatment across all three points of service for etanercept, adalimumab, and anakinra showed that adalimumab was the most cost effective TIB for treatment of RA. Etanercept was more costly than adalimumab with similar effectiveness, while anakinra was both more costly and less effective.
2) For psoriasis, there was insufficient evidence to definitely conclude that treatment effectiveness differed among agents. A cost analysis comparing the expected cost per year of treatment across all three points of service for efalizumab, etanercept, and alefacept showed similar cost effectiveness profiles for all three agents.
3) The UF scenario that placed adalimumab as the sole multi-indication TIB on the UF was the most cost effective scenario.

COMMITTEE ACTION: The P&T Committee voted (16 for, 0 opposed, 0 abstained, and 1 absent) to accept the TIB relative cost effectiveness analysis as presented by the PEC. The Committee concluded that the UF scenario that placed adalimumab as the sole multi-indication TIB on the UF was the most cost effective UF scenario.

C. TIBs – UF Recommendation

COMMITTEE ACTION: Taking into consideration the relative clinical effectiveness and relative cost effectiveness conclusions for the TIBs and other relevant factors, the P&T Committee, based upon its collective professional judgment, voted (13 for, 2 opposed, 1 abstained, and 1 absent) to recommend that adalimumab, efalizumab, and alefacept be maintained as formulary on the UF and that etanercept and anakinra be classified as non-formulary under the UF.

D. TIBs – MN Criteria

Based on the clinical evaluation for etanercept and anakinra, and the conditions for establishing MN for a non-formulary medication provided for in the UF rule, the P&T Committee recommended the following general MN criteria for etanercept and anakinra:

1) Use of formulary alternatives is contraindicated.
2) The patient has experienced or is likely to experience significant adverse effects from formulary alternatives.
3) Formulary agents have resulted or are likely to result in therapeutic failure.
4) Patient previously responded to non-formulary agent and changing to a formulary agent would incur unacceptable risk.
5) (Etanercept only) There is no formulary alternative.

With respect to criterion #4, the P&T Committee's primary concern was for patients stabilized on treatment with etanercept or anakinra.

With respect to criterion #5, the P&T Committee agreed that this in general applies only to etanercept, as multiple formulary alternatives are available for anakinra, which is FDA-indicated only for RA. Etanercept is currently the only TIB indicated for JRA; the other self-administered multi-indication TIB, adalimumab, lacks an indication for plaque psoriasis.

COMMITTEE ACTION: The P&T Committee voted (14 for, 0 opposed, 1 abstained, 2 absent) to approve the MN criteria outlined above.

E. TIBs – UF Implementation Period

The P&T Committee recommended an effective date of the first Wednesday following a 90-day implementation period at the TMOP and TRRx, and at the MTFs no later than a 90-day implementation period. The implementation period will begin immediately following approval by the Director, TMA.

As part of the implementation plan, the P&T Committee also recommended that TMA send a letter to beneficiaries affected by this UF decision to inform them about the change in formulary status for their TIB. A retrospective pharmacy claims analysis revealed that approximately 11,500 DoD beneficiaries have filled a prescription for a non-formulary TIB in the previous quarter.

MTFs will not be allowed to have etanercept or anakinra on their local formularies. MTFs will be able to fill non-formulary requests for these agents only if both of the following conditions are met: 1) the prescription must be written by a MTF provider; MTFs may (but are not required to) fill a prescription for non-formulary TIB written by a non-MTF provider to whom the patient was referred, and 2) MN is established.

COMMITTEE ACTION: The P&T Committee recommended (15 for, 0 opposed, 1 abstained, 1 absent) an effective date of the first Wednesday following a 90-day implementation period at the TMOP and TRRx, and at the MTFs no later than a 90-day implementation period. The implementation period will begin immediately

following the approval by the Director, TMA. The P&T Committee also recommended that letters be sent to educate patients receiving non-formulary TIBs about the change in formulary status.

F. TIBs – PA Requirements, Criteria, and Implementation Period

Currently PA requirements apply to etanercept, adalimumab, anakinra, and efalizumab. A PA is not currently required for alefacept. The P&T Committee agreed that the following PA criteria should apply to alefacept, consistent with FDA-approved labeling and PA requirements for the other TIBs, and with an implementation period consistent with that established for the UF decision in this class.

1) Coverage would be approved for the treatment of:
   - Adult patients with moderate to severe chronic plaque psoriasis who are candidates for systemic therapy or phototherapy

2) Coverage would NOT be approved for:
   - Patients with HIV, patients with a CD4+ T lymphocyte count below normal at start of treatment, immunocompromised patients or those receiving other immunosuppressive agents or phototherapy
   - Children (age < 18 years)

Current PA criteria for etanercept, adalimumab, anakinra, and efalizumab are outlined in Appendix C. The P&T Committee agreed that the PA criteria reflect current FDA labeling and published clinical literature and require no substantive changes. Minor changes to clarify wording and increase consistency, as well as possible future changes to accommodate new FDA indications, will be accomplished on an administrative basis.

COMMITTEE ACTION: The P&T Committee recommended (14 for, 0 opposed, 1 abstained, 2 absent) to recommend 1) that no changes be made to PA criteria for etanercept, adalimumab, anakinra, and efalizumab as outlined in Appendix C; 2) that a PA be required for alefacept under the PA criteria outlined above; and 3) that the effective date for the alefacept PA be timed to coincide with that established for the UF decision in this class.

G. TIBs – QLs

Currently, quantity and/or days supply limits apply to etanercept, adalimumab, and anakinra, as outlined in Appendix C. In general, patients are limited to a 4-week supply of these medications at retail network pharmacies at any one time (no multiple fills for multiple copays) and a 6- to 8-week supply at the TMOP, based on product labeling and packaging. The intent is to limit potential wastage if medications are discontinued or changed.

COMMITTEE ACTION: The P&T Committee recommended (14 for, 0 opposed, 1 abstained, 2 absent) to recommend 1) that no changes be made to existing quantity / days supply limits for etanercept, adalimumab, and anakinra.

H. TIBs – Extended Core Formulary (ECF) Review and Recommendations – Based on the results of the clinical and economic evaluations presented, the P&T Committee

voted (15 for, 0 opposed, 1 abstained, and 1 absent) to recommend that adalimumab be added to the ECF.

COMMITTEE ACTION: The P&T Committee voted (15 for, 0 opposed, 1 abstained, and 1 absent) to recommend that adalimumab be added to the ECF.

9. BCF STATUS OF ROSIGLITAZONE

At the P&T Committee's request, the PEC updated the Committee on the latest news/evidence regarding the safety of thiazolidinedione (TZD) agents, particularly that of rosiglitazone (Avandia), the DoD's BCF TZD. The PEC informed the Committee about recent changes in DoD TZD utilization, evidence (meta-analyses, systematic reviews, and clinical studies) that has emerged in the clinical literature since the last meeting, and a revision to an FDA Alert for rosiglitazone issued 21 May 2007.

The P&T Committee discussed the advantages and disadvantages of removing rosiglitazone and rosiglitazone/metformin (Avandamet) from the BCF. Ultimately, the P&T Committee determined that there was sufficient clinical evidence to justify removal of rosiglitazone and rosiglitazone/metformin from the BCF.

COMMITTEE ACTION: The Committee voted (13 for, 0 opposed, 1 abstained, 3 absent) to remove rosiglitazone and rosiglitazone/metformin from the BCF at this time.

10. BCF / ECF REVIEW

As part of an ongoing plan to systematically review drug classes represented on the BCF, the P&T Committee made recommendations for clarifying BCF listings in two current BCF drug classes, analgesics (meloxicam , cyclobenzaprine, and oxycodone/acetaminophen) and ADHD and narcolepsy agents (methylphenidate IR). Details are outlined in Appendix D.

COMMITTEE ACTION: The P&T Committee recommended the following changes to BCF / ECF listings as outlined in Table 4 (see Appendix D for rationale):

Table 4. Recommended BCF / ECF Changes

Drug class or potential drug class	Current BCF/ECF listing	Recommendation	Vote			
			For	Opposed	Abstained	Absent
Analgesics	BCF – Meloxicam (Mobic) oral	Clarify BCF listing to "meloxicam tablets only"	14	0	1	2
	BCF – Cyclobenzaprine (Flexeril) oral; does not include 5 mg strength	Clarify BCF listing to "cyclobenzaprine IR tablets, 5 and 10 mg"	14	0	1	2
	BCF – Oxycodone 5 mg / acetaminophen 325 mg	Clarify BCF listing to "oxycodone 5 mg / acetaminophen 325 mg tablets"	14	0	1	2
ADHD and Narcolepsy Agents	BCF – methylphenidate IR; methylphenidate ER (specific brand is Concerta); mixed amphetamine salts ER (Adderall XR)	Clarify BCF listing to "methylphenidate IR (excludes Methylin oral solution and chewable tablets), methylphenidate ER (specific brand name is Concerta); mixed amphetamine salts ER (Adderall XR)"	14	0	1	2

11. RE-EVALUATION OF AMLODIPINE'S UF STATUS

On an ongoing basis, the DoD PEC monitors changes in the clinical information, current costs, and utilization trends to evaluate whether the UF status of agents designated as non-formulary needs to be readdressed. At this meeting, the UF status of amlodipine (Norvasc, generics) was re-evaluated due to a significant decrease in cost across all three points of service.

In early 2007, the FDA approved Mylan Pharmaceutical's first-time generic for Norvasc. Until recently, the price for amlodipine, even though available generically, was similar to the price for brand name Norvasc and did not support a change in its UF status.

At the August 2005 P&T Committee meeting, the Committee concluded that in general, amlodipine had similar clinical effectiveness relative to other DHP CCBs in regards to efficacy, safety, and tolerability. In consideration of the Committee's previous relative clinical effectiveness conclusion, a CMA was performed to determine the cost effectiveness of amlodipine relative to the other DHP CCBs included on the UF. The results of the CMA showed amlodipine to be the most-cost effective DHP CCB.

Cost Effectiveness Conclusion – The P&T Committee accepted the conclusions from the cost effectiveness analyses stated above.

COMMITTEE ACTION: The P&T Committee voted (16 for, 0 opposed, 0 abstained, and 1 absent) to accept the relative CEA as presented by the PEC.

A. Amlodipine – UF Recommendation

COMMITTEE ACTION: In view of the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of the DHP CCB, and other relevant factors, the P&T Committee, based upon its collective professional judgment, voted (15 for, 0 opposed, 1 abstained, and 1 absent) to recommend that amlodipine be reclassified as formulary on the UF.

B. Amlodipine – UF Implementation Period

The P&T Committee recommend immediate implementation upon signing of the November 2007 DoD P&T Committee minutes by the Director, TMA.

COMMITTEE ACTION: The P&T Committee recommend (15 for, 0 opposed, 1 abstained and 1 absent) an effective date as the date the Director, TMA signs the minutes.

C. Amlodipine – BCF Review and Recommendation

COMMITTEE ACTION: The P&T Committee considered the BCF status of the DHP CCB agents. Based on the results of the clinical and economic evaluations presented, the Committee voted (15 for, 0 opposed, 1 abstained and 1 absent) to add amlodipine to the BCF.

12. RE-EVALUATION OF NON-FORMULARY AGENTS

The P&T Committee's process for the re-evaluation of non-formulary agents established at the May 2007 meeting was approved by the Director, TMA on 24 June 2007. For this meeting, the PEC applied the appropriate criteria and defined a list of non-formulary drug agents for re-evaluation of UF status (Table 5) for the P&T Committee's consideration. More specifically, the non-formulary agents identified for re-evaluation were: 1) from

drug classes in which UF status was NOT awarded based on condition sets that specified the number of similar agents on the UF (i.e., agents in the same class or subclass); and 2) determined to have similar relative clinical effectiveness (i.e., similar efficacy, safety, and tolerability) compared to similar agents on the UF and not excluded from the UF based on clinical issues alone.

Table 5 – Non-Formulary Agents for Re-Evaluation

Generic Name	Brand Name	UF Class	Generics Shipping
EE 30 mcg; 0.15 mg levonorgestrel	Seasonale	BCs (M30)	Y
EE 30/10 mcg; 0.15 mg levonorgestrel	Seasonique	BCs (M20)	N
EE 35 mcg; 0.4 mg norethindrone	Ovcon-35	BCs (M35)	Y
EE 50 mcg; 1 mg norethindrone	Ovcon-50	BCs (M50)	N
EE 20 mcg; 0.1 mg norethindrone	Loestrin 24 FE	BCs (M20)	N
ciclopirox	Loprox	AF-DERMs	Y
econazole	Spectazole	AF-DERMs	Y
moexipril	Univasc	ACEs	Y
quinapril	Accupril	ACEs	Y
amlodipine	Norvasc	CCBs	Y
nicardipine	Cardene	CCBs	Y
nicardipine SR	Cardene SR	CCBs	N
isradipine IR	Dynacirc	CCBs	Y
isradipine CR	Dynacirc CR	CCBs	N
diltiazem ER HS	Cardizem LA	CCBs	N
verapamil ER HS	Verelan /Covera HS	CCBs	N
bupropion XL	Wellbutrin XL	AD1s	Y (300mg only)
paroxetine CR	Paxil CR	AD1s	N
escitalopram	Lexapro	AD1s	N
verapamil ER / trandolapril	Tarka	Misc HTNs	N
tramadol ER	Ultram ER	Narcotic analgesics	N
timolol maleate	Istalol	EYE-1s	N
timolol hemihydrate	Betimol	EYE-1s	N
tolterodine IR	Detrol IR	OABs	N

Accordingly, the PEC recommended that the following pre-established criteria be applied to each non-formulary agent for re-evaluation of UF status.

1) The non-formulary agent becomes generically available and:

   a) The generic product is "A-rated" as therapeutically equivalent to the brand name product according to the FDA's classification system

   b) The generic market supply is stable and sufficient to meet MHS supply demands.

2) The non-formulary agent is cost effective relative to similar agents on the UF. A non-formulary agent becomes cost effective when:

   c) The non-formulary agent's total weighted average cost per day of treatment is less than or equal to the total weighted average cost per day of treatment for the UF class to which they were compared.

   d) The non-formulary agent's total weighted average cost based on an alternate measure used during the previous review is less than or equal to that for the UF

class to which they were compared. For example, antibiotics may be compared on the cost per course of therapy used to treat a particular condition.

The PEC reminded the DoD P&T Committee that when the pre-established criteria for reclassification are met, the Chairperson of the P&T Committee will call for an electronic vote by the members of the P&T Committee on the matter.

1) Upon a majority vote affirming that the non-formulary drug should be reclassified as generic, that agent will be changed from non-formulary status to formulary status as a generic.
2) Committee members will be briefed on any reclassification of a non-formulary agent at the next meeting of the P&T Committee. This information will be recorded as an information-only item in the meeting minutes. The item will be included in information provided for the BAP's next meeting; however, since the BAP will have already made any comments on the subject, the item will normally not be subject to further BAP comment.

The P&T Committee developed the process for the re-evaluation of non-formulary agents for UF status because it recognized that there are situations in which it would be helpful if a procedure were in place that allowed reclassification of a drug from non-formulary to generic in a more expeditious manner than can be accomplished through the normal quarterly P&T Committee cycle. Such a procedure would be advantageous for both the MHS and its beneficiaries.

COMMITTEE ACTION: The P&T Committee voted (15 for, 0 against, 1 abstained, 1 absent) to recommend that the above list of non-formulary drug agents be re-evaluated for UF status when pre-established criteria are met.

13. CLASS OVERVIEWS

The class overview for the Pulmonary-1 Agents was presented to the P&T Committee. This drug class comprises the short-acting beta agonists, long-acting beta agonists (LABA), inhaled corticosteroids, and corticosteroid/LABA combinations.

The P&T Committee provided expert opinion regarding those clinical outcomes considered most important for the PEC to use in completing the relative clinical effectiveness evaluation and developing the appropriate cost effectiveness models. The clinical and economic analyses of these classes will be completed for a future meeting; no action is necessary.

14. ADJOURNMENT

The second day of the meeting adjourned at 1530 hours on 15 Nov 2007. The next meeting will be 12-13 Feb 2008.

BCF = Basic Core Formulary; ECF = Extended Core Formulary; MN = Medical Necessity; TMOP = TRICARE Mail Order Pharmacy; TRRx = TRICARE Retail Pharmacy program; UF = Uniform Formulary
ER = extended release; IR = immediate release; SR = sustained release; IDD-P = insoluble drug delivery-microParticle
ADHD = Attention Deficit Hyperactivity Disorder; ARBs = Angiotensin Receptor Blockers; ACE Inhibitors = Angiotensin Converting Enzyme Inhibitors; BPH = Benign Prostatic Hyperplasia; CCBs = Calcium Channel Blockers; EE = ethinyl estradiol; GI = gastrointestinal; GABA = gamma-aminobutyric acid; H2 = Histamine-2 receptor; HCTZ = hydrochlorothiazide; MS-DMDs = Multiple Sclerosis Disease-Modifying Drugs; OABs = Overactive Bladder Medications; PDE-5 Inhibitors = Phosphodiesterase-5 inhibitors; PPIs = Proton Pump Inhibitors; TZDs= Thiazolidinediones
*The topical antifungal drug class excludes vaginal products and products for onychomycosis (e.g., ciclopirox topical solution [Penlac])

Appendix B – Newly Approved Drugs. November 2007 DoD P&T Committee Meeting

Medication (Brand name; manufacturer) mechanism of action	**FDA Approval Date & FDA-Approved Indications**	**Committee Recommendation**
Formoterol fumarate inhalation solution (Perforomist, Dey) inhaled LABA	May 07 (launched Oct 07) Long term twice daily (morning and evening) maintenance treatment of bronchoconstriction in patients with COPD, including chronic bronchitis and emphysema. Not intended to treat asthma or acute deterioration of COPD	No UF recommendation at this meeting. Consideration of UF status deferred until inhalational Pulmonary I drugs are reviewed; UF review anticipated within the next 12 months. Quantity limits recommended: ▪ TMOP o #180 unit dose vials per 90 days ▪ Retail Network o #60 unit dose vials per 30 days

Appendix C – Existing Prior Authorization Criteria and Quantity Limits for Targeted Immunomodulatory Biologics

	Adalimumab (Humira)	Etanercept (Enbrel)	Anakinra (Kineret)	Alefacept (Amevive)	Efalizumab (Raptiva)
Prior Authorization (approved PAs are good indefinitely)	Coverage provided for the treatment of: ▪ Moderately to severely active RA in patients 18 years of age or older. ▪ Active arthritis in patients with PsA 18 years of age or older. ▪ Active AS in patients 18 years of age or older. ▪ Moderately to severely active Crohn's disease following an inadequate response to conventional therapy, loss of response to infliximab, or an inability to tolerate infliximab in patients 18 years of age or older. ▪ Coverage NOT provided for concomitant use with anakinra, etanercept, or infliximab	Coverage provided for the treatment of: ▪ Moderately to severely active RA ▪ Active PsA ▪ Active AS ▪ JRA when the patient has an inadequate response to at least one DMARD ▪ Chronic moderate to severe plaque psoriasis when the patient has tried and failed traditional therapy, such as phototherapy (e.g. UVB, PUVA) or systemic therapy (e.g., methotrexate, acitretin or cyclosporine) OR is not a candidate for phototherapy or systemic therapy ▪ Coverage NOT provided for concomitant use with anakinra, etanercept, or infliximab	Coverage provided for the treatment of: ▪ Moderately to severely active RA in patients 18 years of age or older when the patient has had an inadequate response to at least one disease-modifying antirheumatic drug (DMARD). ▪ Coverage NOT provided for concomitant use with anakinra, etanercept, or infliximab	none	Coverage provided for the treatment of: ▪ Adults (age = 18 years) with chronic moderate to severe plaque psoriasis, defined as a minimum body surface area involvement of 10% OR a body surface area involvement of less than 10%, but in critical areas (e.g. palms, soles or face) and interfering with day-to-day activities AND ▪ who have tried and failed traditional therapy, such as phototherapy (e.g. UVB, PUVA) or systemic therapy (e.g., methotrexate, acitretin or cyclosporine) OR are not candidates for phototherapy or systemic therapy AND ▪ for whom a dermatologist recommends treatment. Coverage NOT provided for: ▪ Immunocompromised patients or those receiving immunosuppressive agents. ▪ Children (age < 18 years) ▪ Patients with PsA without plaque psoriasis
Quantity Limits	Maximum quantity dispensed at any one time: 4 weeks supply (2 packs of 2 syringes) in retail and 6 weeks supply (3 packs of 2 syringes) in mail order. Does not apply to the Crohn's Disease starter pack (6 pens for the first 4 weeks of treatment), which is limited to 1 package (6 pens), with no refills.	4-week supply in retail and a 6-week supply in mail order (based on instructions for use on the prescription)	Maximum quantity dispensed at any one time is 4 weeks supply (1 package of 28 syringes) in retail and 8 weeks supply (2 packages of 28 syringes) in mail order		

Appendix D– Basic / Extended Core Formulary (BCF/ECF) Review

Drug Class or Potential Drug Class	BCF / ECF listing	Recommendation/ Rationale
Analgesics	BCF – meloxicam (Mobic) oral	• In Aug 2002, meloxicam (Mobic) tablets were added to the BCF • All tablets are now available in generic formulations • In June 2004 the FDA approved Mobic suspension 7.5 mg/ 5 ml (no generics available) • In the last year, there have been 30 Rxs across all Points of Service • Recommendation: • Clarify BCF listing to "meloxicam tablets only"
	BCF – cyclobenzaprine (Flexeril) oral; does not include 5 mg strength	• In Nov 2003, cyclobenzaprine was clarified to exclude the 5 mg strength due to high cost and availability solely as proprietary Flexeril • All IR products are now available in generic formulations at a cost of ~$0.02/tab • A new cyclobenzaprine ER capsule, Amrix (Cephalon), entered the market in Feb 2007 • Recommendation: • Clarify BCF listing to "cyclobenzaprine IR tablets, 5 and 10 mg"
	BCF – oxycodone 5 mg / acetaminophen 325 mg	• The BCF listing does not clarify tablets or capsules and does not specify the 5 mg / 325 mg product • No capsules are available in this strength • Recommendation • Clarify BCF listing to "oxycodone 5 mg / acetaminophen 325 mg tablets"
ADHD and Narcolepsy Agents	BCF – methylphenidate IR; methylphenidate ER (specific brand is Concerta); mixed amphetamine salts ER (Adderall XR)	• The methylphenidate IR oral tablets are available in generic formulations, and are listed on the PEC website as a BCF item. • The Nov 06 P&T Committee minutes for the ADHD BCF drugs were ambiguous for methylphenidate IR oral solution and chewable tablets, available under the brand name Methylin. These Methylin formulations are the only IR products available for the oral solution and chewable tablets. • The Uniform Formulary search tool BCF listing was erroneous, and the manufacturer of Methylin solution and chewable tablets concluded their products were BCF items. • Since Oct 06, MHS utilization for Methylin has been low, at 7 Rx's dispensed monthly for the solution and 4 Rx's dispensed monthly for the chewable tablets. • A CMA found that Methylin solution and chewable tablets were less cost effective than other methylphenidate IR formulations. • Recommendation: • Clarify BCF listing for ADHD drugs to exclude Methylin oral solution and chewable tablets.

Appendix E – Table of Abbreviations

AB	Alpha Blocker (drug class)
ABA	Adrenergic Beta Blocker (drug class)
ACE	angiotensin converting enzyme
ACR	American College of Rheumatology
ADHD	Attention Deficit Hyperactivity Disorder
AE	adverse event
AS	ankylosing spondylitis
ARB	angiotensin receptor blocker
AUA-SI	American Urological Association Symptom Index
BAP	Beneficiary Advisory Panel
BCF	Basic Core Formulary
BIA	budget impact analysis
BID	twice daily
BP	blood pressure
BPH	benign prostatic hypertrophy
CCB	calcium channel blocker
CEA	cost effectiveness analysis
CFR	Code of Federal Regulations
CI	confidence interval
CMA	cost minimization analysis
CR	controlled release (extended release)
DERP	Drug Effectiveness Review Project (State of Oregon)
DHP	dihydropyridine
DMARD	disease-modifying antirheumatic drugs
DoD	Department of Defense
EE	ethinyl estradiol
ER	extended release
FDA	Food and Drug Administration
FY	fiscal year
HCTZ	hydrochlorothiazide
HF	heart failure
IFIS	intraoperative floppy iris syndrome
IPSS	international prostate symptom score
IL	interleukin
IR	immediate release
JRA	juvenile rheumatoid arthritis
LABA	long-acting beta agonists
LUTS	lower urinary tract symptoms
M20 EE	monophasic contraceptive with 20 mcg ethinyl estradiol
MHS	Military Health System
MI	myocardial infarction
MN	medical necessity
MTF	military treatment facility
MTX	methotrexate
NSR	normal sinus rhythm
PA	prior authorization
PASI	Psoriasis Area and Severity Index
P&T	Pharmacy and Therapeutics
PEC	Pharmacoeconomic Center
PDE-5	Phosphodiesterase type 5
PsA	psoriatic arthritis
Pulm I	Pulmonary I (drug class)
QD	once daily

Appendix E – Table of Abbreviations (continued)

Qmax	urinary flow rate
QoL	quality of life
RAAs	renin-angiotensin antihypertensive (drug class)
RCT	randomized controlled trial
RR	relative risk
TB	tuberculosis
TIBs	Targeted Immunomodulatory Biologics
TMA	TRICARE Management Activity
TMOP	TRICARE Mail Order Pharmacy
TNF-α	Tumor Necrosis Factor alpha
TRRx	TRICARE Retail Pharmacy Network
UC	ulcerative colitis
UF	Uniform Formulary
XR	extended release

DECISION PAPER

DEPARTMENT OF DEFENSE

PHARMACY AND THERAPEUTICS COMMITTEE RECOMMENDATIONS

August 2007

1) **CONVENING**
2) **ATTENDANCE**
3) **REVIEW MINUTES OF LAST MEETING**
4) **ITEMS FOR INFORMATION**
5) **REVIEW OF RECENTLY APPROVED AGENTS**

A. Recently Approved Agents in Classes Not Yet Reviewed for the Uniform Formulary (UF) – The P&T Committee was briefed on four new drugs which were approved by the U.S Food and Drug Administration (FDA) (see Appendix B). The Department of Defense (DoD) Pharmacy and Therapeutics (P&T) Committee determined that these four new drugs fall into drug classes that have not yet been reviewed for UF status; therefore, UF consideration was deferred until drug class reviews are completed. The P&T Committee discussed the need for quantity limits (QLs) requirements for budesonide/formoterol (Symbicort) oral inhaler. (See paragraph 5A on page 20 of the P&T Committee minutes).

COMMITTEE ACTION: QUANTITY LIMITS – The P&T Committee voted (13 for, 0 opposed, 1 abstained, 3 absent) to recommend QLs for budesonide/ formoterol of 1 inhaler per 30 days, 3 inhalers per 90 days.

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

B. Renin Angiotensin Antihypertensive – Aliskiren (Tekturna)

Background – In May 2007, the P&T Committee re-classified the angiotensin converting enzyme (ACE) inhibitors, angiotensin receptor blockers (ARBs), ARB/calcium channel blockers combinations and any newly approved antihypertensive drugs affecting the renin system into a single drug class, the Renin-Angiotensin Antihypertensives (RAAs). Aliskiren is the first new drug in the RAA class.

Relative Clinical Effectiveness Conclusion – the P&T Committee voted (14 for, 1 opposed, 0 abstained, 2 absent) to accept the clinical effectiveness conclusions stated below. The one opposing vote was due to the opinion that there was insufficient clinical experience with aliskiren.

a) Aliskiren is a new antihypertensive agent with a novel mechanism of action as a direct renin inhibitor.

b) Aliskiren's blood pressure (BP) lowering effects are similar to those achieved with other antihypertensives, but it does not show improved efficacy compared to other classes of antihypertensive agents.

c) Combination therapy of aliskiren with ACE inhibitors, diuretics and ARBs has shown additive BP lowering effects compared to monotherapy with other antihypertensive agents.

d) Several other safe, once-daily, less costly antihypertensive drugs are available that have proven clinical outcomes (e.g., ACE inhibitors, ARBs, diuretics).

e) The long-term adverse event profile of aliskiren is unknown; diarrhea is the most commonly reported adverse event and the discontinuation rate is similar to placebo.

f) Clinical outcomes of aliskiren are unknown. Trials are underway, with initial results anticipated in November 2007.

Relative Cost Effectiveness Conclusion – the P&T Committee concluded (14 for, 0 opposed, 1 abstained, 2 absent) that:

Although aliskiren was somewhat more costly relative to the ARBs designated as formulary on the UF, the P&T Committee was reluctant to designate aliskiren non-formulary at this time given its novel mechanism of action and the anticipated availability of clinical outcomes data that would enable the P&T Committee to more definitively assess its value relative to other anti-hypertensives.

1) ***COMMITTEE ACTION: UF RECOMMENDATION*** –Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations, and other relevant factors, the P&T Committee, based upon its collective professional judgment, voted (10 for, 4 opposed, 1 abstained, 2 absent) to recommend that aliskiren be classified as formulary on the UF. The four opposing votes were cast due to the opinion that there was insufficient evidence to recommend formulary placement; the one abstaining vote was due to the opinion that there was a lack of sufficient cost effectiveness compared to the ARBs. (See paragraph 5B on pages 20-23 of the P&T Committee minutes).

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows: "On condition that active surveillance be initiated."

C. Nasal Corticosteroid – Fluticasone Furoate (Veramyst)

Background – The P&T Committee reviewed the nasal corticosteroid drug class in November 2005; fluticasone propionate (Flonase, generics), mometasone furoate (Nasonex), and flunisolide (Nasarel) were designated as formulary on the UF, while beclomethasone dipropionate (Beconase AQ, Vancenase AQ), budesonide (Rhinocort AQ), and triamcinolone (Nasacort AQ, Nasacort HFA) were classified as non-formulary. Fluticasone furoate is a new nasal corticosteroid that replaces the

propionate ester of fluticasone propionate with a furoate ester. *In vitro* claims of enhanced glucocorticoid receptor binding *in-vitro* have not translated into enhanced clinical effectiveness.

There is insufficient evidence to determine if there are clinically relevant differences between Veramyst and Flonase; one head-to-head trial in patients older than 12 years of age with SAR showed that Veramyst was not inferior to Flonase in terms of changes from baseline in Total Nasal Symptom Score. Veramyst's adverse effect profile appears similar to other nasal corticosteroids. The P&T Committee also evaluated differences in the delivery device, ease of administration, and particle size of Veramyst compared to other nasal corticosteroids, but did not find a unique advantage or disadvantage relative to fluticasone propionate or mometasone furoate.

Relative Clinical Effectiveness Conclusion: The DoD P&T Committee concluded (12 for, 0 opposed, 1 abstained, 4 absent) that:

> Fluticasone furoate has no clinically significant differences with respect to safety, efficacy, or tolerability, when compared to other nasal corticosteroids included on the UF.

Relative Cost Effectiveness Conclusion: The P&T Committee concluded (15 for, 0 opposed, 0 abstained, 2 absent) that:

> Fluticasone furoate was not cost effective relative to the UF nasal corticosteroids.

1) ***COMMITTEE ACTION: UF RECOMMENDATION*** – Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of fluticasone furoate, and other relevant factors, the P&T Committee, based upon its collective professional judgment, voted (12 for, 0 opposed, 1 abstained, 4 absent) to recommend that fluticasone furoate be classified as non-formulary under the UF. (See paragraph 5C on pages 23-25 of the P&T Committee minutes).

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

2) ***COMMITTEE ACTION: MEDICAL NECESSITY (MN) CRITERIA*** – Based on the clinical evaluation of fluticasone furoate and the conditions for establishing medical necessity of a non-formulary medication provided for in the UF rule, the P&T Committee recommended (14 for, 0 opposed, 1 abstained, 2 absent) medical necessity criteria for the nasal corticosteroids. (See paragraph 5C on page 26 of the P&T Committee minutes for the criteria).

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

3) ***COMMITTEE ACTION: IMPLEMENTATION PERIOD*** – The P&T Committee voted (14 for, 0 opposed, 1 abstained, 2 absent) to recommend an

effective date of the first Wednesday following a 60-day implementation period in the TRICARE Mail Order Pharmacy (TMOP) and TRICARE Retail Pharmacy (TRRx) network, and at military treatment facilities (MTFs) no later than a 60-day implementation period. The implementation period will begin immediately following approval by the Director, TRICARE Management Activity (TMA). Committee members directed that if operationally feasible, the $22 co-pay should start immediately upon signing of the minutes for new users; the $22 co-pay would go into effect after the 60-day implementation date for current fluticasone furoate users. (See paragraph 5C on page 26 of the P&T Committee minutes.)

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

4) ***COMMITTEE ACTION: QUANTITY LIMITS*** - The P&T Committee voted (14 for, 0 opposed, 1 abstained, 2 absent) to recommend a QL for fluticasone furoate in the TRRx of 1 inhaler device per 30 days and a QL in the TMOP of 3 inhaler devices per 90 days. (See paragraph 5C on page 26 of the P&T Committee minutes.)

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

6) DRUG CLASS REVIEW – NEWER ANTIHISTAMINE (NA) DRUG CLASS

The P&T Committee evaluated the relative clinical effectiveness of the NA agents. The NA drug class includes the following agents: loratadine (Claritin, generics), acrivastine/ pseudoephedrine (Semprex-D), fexofenadine (Allegra, generics), cetirizine (Zyrtec), and desloratadine (Clarinex). The class also includes combinations of all of the single agent products with pseudoephedrine. As of June 2007, about three million Military Health System (MHS) prescriptions for these agents were filled annually. The NA drug class was ranked #5 in terms of expenditures ($178 million) in FY 2006 .

The brand-only agents in this class are desloratadine, acrivastine/pseudoephedrine and cetirizine. Loratadine and fexofenadine are available as generics. Loratadine is only available over-the-counter (OTC). Cetirizine is expected to become available OTC by the end of 2007 and generic cetirizine OTC products are expected to be marketed in the first quarter of calendar year 2008. Marketing for a very recently approved product, levocetirizine (Xyzal), is expected to begin in September/October of 2007.

Relative Clinical Effectiveness Conclusion – The P&T Committee concluded (14 for, 0 opposed, 1 abstained, 2 absent) that:

1) Based on randomized placebo-controlled trials, cetirizine, desloratadine and loratadine are more efficacious than placebo for the symptomatic relief of seasonal allergic rhinitis (SAR), perennial allergic rhinitis (PAR) and chronic idiopathic urticaria (CIU). Fexofenadine is more efficacious than placebo for the

symptomatic relief of SAR and CIU. Acrivastine/pseudoephedrine is more efficacious than placebo for the symptomatic relief of SAR.

2) Based on six comparative trials in adults with SAR, there is insufficient evidence to suggest that there are clinically significant differences between cetirizine, fexofenadine, and loratadine, or desloratadine and fexofenadine. There is insufficient evidence to compare any of the agents in children less than 12 years old with this condition.
3) For the treatment of PAR in adults, there is insufficient evidence to suggest clinically significant differences between the agents. In children 2 to 6 years old, limited evidence based on one fair/poor quality comparative trial suggests that cetirizine may be more efficacious than loratadine with PAR.
4) For the treatment of CIU in adults, limited evidence based on two poor quality comparative trial suggests suggest that loratadine may be more efficacious than cetirizine for total symptom score reductions (but not response time), and cetirizine may be more efficacious than fexofenadine. In children, only cetirizine has evidence of efficacy for the treatment of CIU in children, based on both an active- and placebo-controlled trial.
5) The NAs appear to have similar adverse effect profiles and to result in similar low rates of discontinuation due to adverse events in clinical trials. There do not appear to be any major disadvantages for any one agent with respect to drug-drug interactions.
6) No NA appears preferable in hepatic impaired, renal impaired and pediatric patients. Loratadine, cetirizine and acrivastine/pseudoephedrine are FDA pregnancy category B, while desloratadine, fexofenadine and the combination products containing pseudoephedrine are FDA pregnancy category C.
7) All the parent products have multiple dosage forms and a pseudoephedrine-containing combination product.
8) It is likely that at least one NA is needed for adequate clinical coverage, based on provider responses regarding prescribing practices and likely patient response.
9) Loratadine has been identified as a candidate drug for the DoD OTC Demonstration Program.

Cost Effectiveness Conclusion – The P&T Committee concluded (15 for, 0 opposed, 0 abstained, 2 absent) that:

1) Desloratadine and desloratadine/pseudoephedrine were not cost effective relative to other comparable agents in the newer antihistamine class.
2) The UF scenario that placed desloratadine and desloratadine/pseudoephedrine as non-formulary was the most cost effective scenario.

A. COMMITTEE ACTION: UF RECOMMENDATION – In view of the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of the NAs, and other relevant factors, the P&T Committee, based upon its collective professional judgment, voted (14 for, 0 opposed, 1 abstained, and 2 absent) to

recommend the following. (See paragraph 6C on page 33 of the P&T Committee minutes.)

1) Fexofenadine, fexofenadine/pseudoephedrine, cetirizine, cetirizine/ pseudoephedrine , and acrivastine/pseudoephedrine should be maintained as formulary on the UF.
2) Desloratadine and desloratadine/pseudoephedrine should be classified as non-formulary under the UF.
3) Loratadine and loratadine/pseudoephedrine should be added to the UF for purposes of the TRICARE OTC Demonstration Program.
4) At such time as cetirizine and cetirizine/pseudoephedrine are made available OTC, both products should be maintained on the UF for purposes of the TRICARE OTC Demonstration Program.
5) Desloratadine and desloratadine/pseudoephedrine should be reclassified as generic on the UF when the generic products are available and cost effective relative to similar agents in the newer antihistamine class.

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

B. COMMITTEE ACTION: MN CRITERIA – Based on the clinical evaluation for desloratadine and desloratadine/pseudoephedrine, and the conditions for establishing MN for a non-formulary medication provided for in the UF rule, the P&T Committee recommended (14 for, 0 opposed, 1 abstained, 2 absent) MN criteria for desloratadine and desloratadine/pseudoephedrine. (See paragraph 6D on page 34 of the P&T Committee minutes.)

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

C. COMMITTEE ACTION: IMPLEMENTATION PERIOD – The P&T Committee recommended (14 for, 0 opposed, 1 abstained, 2 absent) an effective date of the first Wednesday following a 90-day implementation period in the TMOP and TRRx, and no longer than a 90-day implementation period at MTFs. The implementation period will begin immediately following the approval by the Director, TMA. (See paragraph 6E on page 34 of the P&T Committee minutes.)

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

D. COMMITTEE ACTION: BASIC CORE FORMULARY (BCF) RECOMMENDATION – Based on the results of the clinical and economic evaluations presented, the P&T Committee voted (14 for, 0 opposed, 1 abstained, and

2 absent) to recommend that the current BCF listing for this class be maintained, requiring each MTF to carry at least one single ingredient agent from the NA class (loratadine, cetirizine, or fexofenadine) on their local formulary, including at least one dosage form suitable for pediatric use. (See paragraph 6F on page 34 of the P&T Committee minutes.)

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

7) DRUG CLASS REVIEW – LEUKOTRIENE MODIFIERS (LMs)

The P&T Committee evaluated the relative clinical effectiveness of the LM agents. The LM class is comprised of two leukotriene receptor antagonists, montelukast (Singulair) and zafirlukast (Accolate); and one 5-lipoxygenase inhibitor, zileuton (Zyflo). A controlled release formulation of zileuton (Zyflo CR) has been approved by the FDA, but is not yet commercially available.

Currently montelukast is the only BCF LM agent. None of the LMs are available in a generic formulation. The LM drug class accounted for $101 million dollars in MHS expenditures in FY 2006, and is ranked #16 in terms of total expenditures during that time period. Over 97% of the utilization is for montelukast; from June 2006 to May 2007, there were over 300,000 montelukast utilizers in the MHS, over 3,000 zafirlukast utilizers and only 300 zileuton utilizers.

Relative Clinical Effectiveness Conclusion: The P&T Committee voted (14 for, 0 opposed, 0 abstained, 3 absent) to accept the following clinical effectiveness conclusion:

a) For the treatment of asthma, National Heart, Lung and Blood Institute National Asthma Education Prevention Program guidelines include LMs as an alternative, but not preferred therapy. LMs are more effective than placebo in controlling asthma symptoms, but are less effective than inhaled corticosteroids (ICS), and are less effective when added on to long-acting beta agonist (LABA) vs. use of a LABA with ICS. Addition of a LM to ICS provides modest benefit over use of the ICS as monotherapy.

b) In placebo-controlled trials for asthma, the three LMs montelukast, zafirlukast, and zileuton demonstrate clinical effectiveness in endpoints such as reduction in exacerbations, improvements in forced expiratory volume in 1 second (FEV1), asthma symptoms scores and short acting beta-agonist use. There is insufficient evidence to determine whether one LM is more efficacious at controlling asthma symptoms than another.

c) Limited evidence suggests that LMs may permit a reduced ICS dose, or could be used in patients resistant to or unable to tolerate inhaled steroids. The extent or clinical significance of this "steroid sparing" effect is uncertain.

d) Montelukast is the only LM that is FDA approved for the treatment of allergic rhinitis (AR), and is specifically approved for both SAR and PAR. There are a few small clinical trials that evaluate zafirlukast in the treatment of allergic

rhinitis, but they fail to consistently show efficacy. There is no data to support the use of zileuton in AR.

e) For AR, meta-analyses show that LMs are superior to placebo in clinically relevant AR endpoints such as rhinitis symptom scores and rhinoconjunctivitis quality of life scores; however, the treatment effect is modest. When compared to antihistamines, the LMs show relatively similar efficacy. Nasal corticosteroids (NCS) are clinically superior to montelukast in all clinical endpoints studied. Combinations of an LM with an antihistamine are modestly more effective than either agent alone, but not superior to NCS in improving nasal symptoms of AR.

f) In the pediatric population, montelukast is approved for use in SAR in children age two years and older, and for PAR in age 6 months and older. However, published clinical trial data is limited in the pediatric population, and is primarily based on safety. In two studies in children with PAR, montelukast was less efficacious than cetirizine in most of the endpoints studied.

g) In regard to safety and tolerability, zileuton has been associated with hepato-toxicity, requires liver function test monitoring, and is contraindicated in patients with active liver disease. Zafirlukast has also been associated with hepatotoxicity including liver failure and death; however, this data is from spontaneously reported adverse event reports and must be interpreted cautiously. Zafirlukast and zileuton are associated with more clinically significant drug interactions than montelukast.

h) In regard to other factors, montelukast has the advantage of a greater number of FDA approved indications, pediatric indications, less frequent dosing (once daily versus twice and four-times daily for zafirlukast and zileuton), and availability of alternative dosage formulations.

i) Overall, based on clinical issues alone, montelukast is preferred over zafirlukast, which in turn is preferred over zileuton.

Relative Cost Effectiveness Conclusion – the P&T Committee concluded (14 for, 0 opposed, 1 abstained, and 2 absent) that:

a) Zafirlukast was the least costly agent in the class; montelukast was more costly relative to zafirlukast but provided additional indications, a better adverse event profile, multiple dosage forms, and more evidence in pediatrics than the other agents in the class; zileuton was not cost effective relative to the other products.

b) LMs are not cost effective in the treatment of AR relative to antihistamines and nasal corticosteroids and should not be considered as first-line therapy in the treatment of AR.

c) The Committee concluded that the UF scenario that placed zafirlukast and montelukast on formulary with a step therapy/prior authorization (PA) program required for use in AR was the scenario that resulted in the lowest expected expenditures in the LM class.

A. COMMITTEE ACTION: STEP THERAPY RECOMMENDATION – Although the committee agreed that the LMs are not cost effective for AR, the Committee

voted (6 for, 8 opposed, 1 abstained, and 2 absent) against enacting a step therapy/PA policy for use of LMs in the management of AR. Similar policies have recently been initiated with other drug classes in the MHS and the Committee felt that the most prudent course of action at this time was to delay enacting another step therapy/PA policy. Instead, the PEC will gather additional evidence about the effect of the other step therapy/PA policies recently implemented in the MHS while educating MTF providers to minimize the use of LMs for the management of AR. The PEC will also monitor utilization in the LM class. If the use of LMs for AR continues to proliferate, the Committee will review the class again to determine if further action is required. (See paragraph 7C on page 44 of the P&T Committee minutes.)

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows: "ASD(HA) urges that these patients be followed re: possible CV +/or oncologic benefits or AE's."

B. ***COMMITTEE ACTION: UF RECOMMENDATION*** – In view of the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of the LMs, and other relevant factors, the P&T Committee, based upon its collective professional judgment, voted (14 for, 0 opposed, 1 abstained, and 2 absent) to recommend that zafirlukast and montelukast be maintained as formulary on the UF and that zileuton be classified as non-formulary under the UF. (See paragraph 7D on page 43 of the P&T Committee minutes.)

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

C. ***COMMITTEE ACTION: MN CRITERIA*** – Based on the clinical evaluation for zileuton and the conditions for establishing MN for a non-formulary medication provided for in the UF rule, the P&T Committee recommended (14 for, 0 opposed, 1 abstained, 2 absent) MN criteria for zileuton. (See paragraph 7E on pages 43-44 of the P&T Committee minutes.)

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

D. ***COMMITTEE ACTION: IMPLEMENTATION PERIOD*** – The P&T Committee recommended (13 for, 1 opposed, 1 abstained, 2 absent) an effective date of the first Wednesday following a 90-day implementation period at the TMOP and TRRx, and no later than a 90-day implementation period at MTFs. The implementation period will begin immediately following the approval by the Director, TMA. (See paragraph 7F on page 44 of the P&T Committee minutes.)

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

E. COMMITTEE ACTION: BCF RECOMMENDATION – The P&T Committee considered the BCF status of the LM agents. Based on the results of the clinical and economic evaluations presented, the P&T Committee voted (13 for, 1 opposed, 1 abstained, and 2 absent) to recommend that montelukast be retained on the BCF (specific formulations include tablets, chewable tablets, and oral granules). (See paragraph 7G on page 44 of the P&T Committee minutes.)

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

8) DRUG CLASS REVIEW – GROWTH STIMULATING AGENTS (GSAs)

The P&T Committee evaluated the relative clinical effectiveness of the GSAs. This class is divided into two subclasses: growth hormone (GH) agents (somatropin products) and insulin-like growth factor-1 (IGF-1) agents (mecasermin). The GSA drug class accounted for about $23 million in MHS expenditures in FY 2006.

This class of drugs includes only two molecular entities, somatropin and mecasermin. There are multiple competing somatropin products. The majority of these are indicated for the treatment of GH deficiency (GHD), which is the most common use. Mecasermin is an orphan drug approved by the FDA in 2005 to treat severe primary insulin-like growth factor deficiency (IGFD), which affects a very small number of patients (about 6,000 in the United States).

Relative Clinical Effectiveness Conclusion: The P&T Committee concluded (15 for, 0 opposed, 0 abstained, 2 absent) that:

a) Somatropin products appear to be safe and efficacious for the treatment of various growth-related conditions and for a few specialized non-growth related conditions.

b) There are no studies comparing any somatropin product to another for any given indication. Given that all of the products contain the same concentration (3 IU rhGH/mg) of bioidentical recombinant human GH, they are unlikely to differ in efficacy for the treatment of growth-related or other disorders.

c) There are potential differences between somatropin products with respect to delivery devices, formulations, and stability/storage requirements. Differences that may favor particular products include availability of a pen device (preferably along with a vial/syringe product); the ability to use the pen device without having to do dose conversions, and the ability to store products at room temperature before or after initial use.

d) Mecasermin is safe and efficacious for severe IGFD, a much rarer condition than GHD. It is the only product available for the treatment of this condition.

e) Based on clinical issues alone, there are no compelling reasons to classify any of the GSA agents as non-formulary under the UF.

Relative Cost Effectiveness Conclusion: the P&T Committee concluded (15 for, 0 opposed, 0 abstained, and 2 absent) that:

a) Mecasermin (Increlex) and two somatropin products (Zorbtive and Serostim) have a specific niche in therapy and offer sufficient value on a cost/mg basis relative to the other agents within the therapeutic class.

b) Tev-Tropin was the most cost effective somatropin agent based on cost minimization analysis. However, the product offers fewer features than most other growth stimulating agent product lines.

c) Two somatropin product lines, Norditropin and Nutropin, offered more features (pen dosage forms, storage at room temperature, and ease of use) at a middle range of cost.

d) The budget impact analysis results showed that the most cost effective formulary strategy for the somatropin products was the combination of the Tev-Tropin and the Norditropin and Nutropin product lines.

A. COMMITTEE ACTION: UF RECOMMENDATION – Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of the GSAs, and other relevant factors, the P&T Committee, based upon its collective professional judgment, voted (13 for, 0 opposed, 1 abstained, 3 absent) to recommend that Tev-Tropin, Nutropin, Nutropin AQ, Norditropin, Nortropin Nordiflex, Serostim, Zorbtive, and Increlex be maintained as formulary on the UF and that the Genotropin, Humatrope, Saizen and Omnitrope brands of somatropin be classified as non-formulary under the UF. (See paragraph 8C on page 57 of the P&T Committee minutes.)

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

B. COMMITTEE ACTION: MN CRITERIA – Based on the clinical evaluation and the conditions for establishing MN for a non-formulary medication provided for in the UF rule, the P&T Committee recommended (13 for, 0 opposed, 1 abstained, 3 absent) MN criteria for the somatropin products Genotropin, Humatrope, Saizen and Omnitrope. (See paragraph 8D on page 57 of the P&T Committee minutes.)

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

C. COMMITTEE ACTION: IMPLEMENTATION PERIOD – The P&T Committee recommended (13 for, 0 opposed, 1 abstained, 3 absent) an effective date of the first Wednesday following a 60-day implementation period at the TMOP and TRRx, and at the MTFs no later than a 60-day implementation period. The implementation period will begin immediately following the approval by the Director, TMA. (See paragraph 8E on pages 57-58 of the P&T Committee minutes.)

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

D. COMMITTEE ACTION: PA CRITERIA – Currently, PA criteria apply to both GH (somatropin products) and mecasermin (Increlex). The P&T Committee recommended (14 for, 0 opposed, 1 abstained, 2 absent) PA criteria for GH (somatropin products) and mecasermin (Increlex). Changes from previous GH (somatropin) criteria are the addition of Noonan's Syndrome and Short Stature Homeobox gene (SHOX) deficiency as covered uses; no changes were recommended to mecasermin criteria. (See paragraph 8F on pages 58-59 of the P&T Committee minutes.)

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

E. COMMITTEE ACTION: EXTENDED CORE FORMULARY (ECF) RECOMMENDATION – Based on the results of the clinical and economic evaluations presented, the P&T Committee voted (13 for, 0 opposed, 1 abstained, and 3 absent) to recommend that Norditropin and Norditropin / Nordiflex be added to the ECF. (See paragraph 8G on page 59 of the P&T Committee minutes.)

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

9) QUANTITY LIMITS

A. COMMITTEE ACTION: QL FOR RIZATRIPTAN (MAXALT) – The Committee voted (14 for, 0 opposed, 1 abstained, 2 absent) to recommend changing the QL for rizatriptan tablets and orally disintegrating tablets (Maxalt, Maxalt MLT) to 12 tablets per 30 days, or 36 tablets per 90 days. (See paragraph 9A on page 59 of the P&T Committee minutes.)

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

10) BCF STATUS OF ROSIGLITAZONE

The PEC updated the P&T Committee on the two recent alerts issued by the FDA regarding rosiglitazone (Avandia). The P&T Committee discussed the advantages and disadvantages of removing rosiglitazone from the BCF. Ultimately, the P&T Committee determined that there was insufficient clinical evidence to justify removal of rosiglitazone from the BCF at this time. The PEC will update the P&T Committee as more

information becomes available. (See paragraph 10 on pages 59-60 of the P&T Committee minutes.)

***COMMITTEE ACTION*:** The Committee voted (7 for, 6 opposed, 1 abstained, 3 absent) to retain rosiglitazone on the BCF at this time.

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

11) BCF / ECF REVIEW

The P&T Committee agreed with a plan to systematically review drug classes represented on the BCF and ECF over the next few meetings with the goals of: 1) removing obsolete medications, 2) defining BCF listings more specifically, 3) reframing or revising BCF listings to be compatible with drug classes as defined or outlined by the P&T Committee, and 4) assessing the need for future review.

The P&T Committee made initial recommendations for clarifying BCF listings in three drug classes or potential drug classes, including atypical antipsychotics (quetiapine and risperidone), osteoporosis agents (alendronate / vitamin D), and cough-cold medications (guaifenesin/pseudoephedrine).

COMMITTEE ACTION: The P&T Committee recommended the following changes to BCF / ECF listings. (See paragraph 11 on page 60 of the P&T Committee minutes and Appendix C).

Drug class or potential drug class	Current BCF / ECF listing	Recommendation	Vote			
			For	Opposed	Abstained	Absent
Atypical antipsychotics	BCF – "Quetiapine"	Clarify BCF listing to: "quetiapine tablets, immediate and extended release"	14	0	1	2
	BCF – "Risperidone oral; does not include orally disintegrating tablets (Risperdal Redi-tabs)"	Clarify BCF listing to: "Risperidone tablets and solution, does not include orally disintegrating tablets"	14	0	1	2
Osteoporosis agents	BCF – "Alendronate 70 mg / vitamin D 2800 IU (Fosamax Plus D)"	Clarify BCF listing to specify new product with higher strength of vitamin D – "Alendronate 70 mg/vitamin D 5600 IU tablets"	14	0	1	2
Cough-cold medications	BCF – "Guaifenesin 600 / PSE 120 mg ER oral"	Remove from BCF	14	0	1	2

Department of Defense
Pharmacy and Therapeutics Committee Minutes
August 2007

1. CONVENING

The Department of Defense (DoD) Pharmacy and Therapeutics (P&T) Committee convened at 0800 hours on 14-15 Aug 2007 at the DoD Pharmacoeconomic Center (PEC), Fort Sam Houston, Texas.

2. ATTENDANCE

A. Voting Members Present

CAPT Patricia Buss, MC, USN	DoD P&T Committee Chair
LTC Brett Kelly, MSC, USA	DoD P&T Committee Recorder
CAPT William Blanche, MSC, USN	DoD Pharmacy Programs, TMA
Capt Jeremy King, MC	Air Force, OB/GYN Physician
Lt Col Brian Crownover, MC	Air Force, Physician at Large
Col Everett McAllister, BSC	Air Force, Pharmacy Officer
LCDR Ronnie Garcia, MC *for* LCDR Michelle Perrelló, MC	Navy, Internal Medicine Physician
LCDR Scott Akins, MC	Navy, Pediatrics Physician Alternate
CDR David Tanen, MC	Navy, Physician at Large
CAPT David Price, MSC	Navy, Pharmacy Officer
COL Doreen Lounsbery, MC	Army, Internal Medicine Physician
COL Karl R. Kerchief, MC	Army, Family Practice Physician
LTC Peter Bulatao, MSC *for* COL Isiah Harper, MSC	Army, Pharmacy Officer
CAPT Vernon Lew, USPHS	Coast Guard, Pharmacy Officer
Mr. Joe Canzolino, RPh.	Department of Veterans Affairs

B. Voting Members Absent

Lt Col Roger Piepenbrink, MC	Air Force, Internal Medicine Physician
COL Ted Cieslak, MC	Army, Physician at Large

C. Non-Voting Members Present

COL Kent Maneval, MSC, USA	Defense Medical Standardization Board
Lt Col Paul Hoerner, BSC, USAF	Deputy Director, DoD Patient Safety Center
CDR Kim Lefebvre, MSC	Defense Supply Center Philadelphia
Major Pete Trang, BSC, USAF	Defense Supply Center Philadelphia
Mr. Howard Altschwager	Assistant General Counsel, TMA
LT Thomas Jenkins, MSC, USN	TMA Aurora

D. Non-Voting Members Absent

Martha Taft	Health Plans Operations, TMA

E. Others Present

Col Nancy Misel, BSC, USAF	IMA DoD Pharmacoeconomic Center
Lt Col James McCrary, MC, USAF	DoD Pharmacoeconomic Center
LTC Chris Conrad, MC, USA	DoD Pharmacoeconomic Center
Maj Wade Tiller, BSC, USAF	DoD Pharmacoeconomic Center
Maj Josh Devine, BSC, USAF	DoD Pharmacoeconomic Center
CPT Josh Napier, MC, USA	DoD Pharmacoeconomic Center
Shana Trice, Pharm.D.	DoD Pharmacoeconomic Center
David Bretzke, Pharm.D.	DoD Pharmacoeconomic Center
Angela Allerman, Pharm.D.	DoD Pharmacoeconomic Center
Eugene Moore, Pharm.D.	DoD Pharmacoeconomic Center
Julie Liss, Pharm.D.	DoD Pharmacoeconomic Center
Elizabeth Hearin, Pharm.D.	DoD Pharmacoeconomic Center
David Meade, Pharm.D.	DoD Pharmacoeconomic Center
Harsha Mistry, Pharm.D.	DoD Pharmacoeconomic Center
Todd Semla, Pharm.D.	VAPBM
Bill Coffenberry	TMA Contracting
Brenda Agner	TMA Contracting
Beth Spearman	TMA/POD
CDR Michael J. Contos	USPHS, IHS

3. REVIEW MINUTES OF LAST MEETING

A. Corrections to the Minutes – May 2007 DoD P&T Committee meeting minutes were approved as written, with no corrections noted.

B. Approval of May Minutes – Dr. Samuel Ward Casscells, III., M.D., approved the minutes of the May 2007 DoD P&T Committee meeting on 24 July 2007.

4. ITEMS FOR INFORMATION

TRICARE Management Activity (TMA) and DoD PEC staff members briefed the P&T Committee on the following:

A. Beneficiary Advisory Panel (BAP) Briefing – CAPT Buss briefed the members of the P&T Committee regarding the June 2007 BAP meeting. The P&T Committee was briefed on BAP comments regarding the DoD P&T Committee's Uniform Formulary (UF) and implementation recommendations.

B. Implementation Status of UF Decisions – The PEC briefed the members of the P&T Committee on the progress of implementation for drug classes reviewed for UF status since February 2005.

C. Status of Newer Sedative Hypnotic Agents (SED-1) Step Therapy Program – The PEC briefed the members of the P&T Committee on a preliminary analysis of the SED-1 Step Therapy Program. The analysis examined the first week of SED-1 transactions (1 – 7 August) following the 1 August 2007 implementation date. During the observation period, 23,790 patients submitted a prescription for a SED-1. A total of 1,592 patients had claims stopped by the Step Therapy Program's automated profile review (APR) process. Of these patients, 771 (48%) subsequently received a SED-1 prescription through 10 August. This represents a window as short as 3 days and is unlikely to be a fair assessment of the Step Therapy Program; the PEC will continue to monitor as more data becomes available. Of patients who subsequently received a SED-1 prescription, 576 (75%) received the preferred product, Ambien IR.

D. Status of Fentanyl Patch Safety Program/Prior Authorization (PA) - The PEC briefed the members of the P&T Committee on a preliminary analysis of the Fentanyl Patch Safety Program. The analysis examined the first week of fentanyl patch transactions (1 – 7 August) following the 1 August 2007 implementation date. During the observation period, 2,732 patients submitted a fentanyl patch prescription. A total of 314 patients had claims stopped by the APR process. Of these patients, 255 (81%) subsequently received a fentanyl patch prescription and 59 (19%) did not, through 10 August (minimum 3-day window). Approximately 11% of patients (314/2732) were affected by the Fentanyl Patch Safety Program.

E. Administrative Actions – Modification of Medical Necessity (MN) Criteria for Duloxetine (Cymbalta) and Pregabalin (Lyrica) – Both of these medications recently gained U.S Food and Drug Administration (FDA) approval for new indications: duloxetine for the treatment of generalized anxiety disorder (February 2007) and pregabalin for the treatment of fibromyalgia (June 2007). MN criteria for these two non-formulary medications are interrelated, since duloxetine also has clinical evidence supporting efficacy in fibromyalgia. The PEC obtained input from members of the P&T Committee regarding the best way to make changes to the MN criteria for these two medications. Changes to MN criteria will be made administratively.

- *Duloxetine for Generalized Anxiety Disorder (GAD)* – Current duloxetine MN criteria allow for the use of the non-formulary serotonin norepinephrine reuptake inhibitor (SNRI) duloxetine in patients treated for depression or other psychiatric illnesses who require treatment with an SNRI (e.g., due to failure of selective serotonin reuptake inhibitor [SSRI] therapy) and who have failed an adequate trial, been unable to tolerate, or have contraindications to the SNRI venlafaxine, which is on the UF. Both venlafaxine and duloxetine are FDA-approved for the treatment of GAD; other medications are FDA-approved either for GAD (e.g., paroxetine, escitalopram) or anxiety in general (e.g., buspirone, lorazepam, alprazolam), or have clinical evidence supporting their use (e.g., sertraline). Based on the results of one head-to-head trial [Hartford et al, 2007] and indirect evidence from placebo-controlled trials with duloxetine and venlafaxine, there is insufficient evidence to conclude that either agent is safer or more efficacious for the treatment of GAD; more clinical evidence is available for venlafaxine. Accordingly, the P&T Committee agreed that the MN criteria were adequate as stated.
- *Pregabalin for Fibromyalgia* – Fibromyalgia is a poorly understood, multifactorial condition that is diagnosed based on a history of widespread pain (bilateral, upper & lower body, spine) and often accompanied by fatigue, difficulty sleeping, and depression. American College of Rheumatology (ACR) criteria, which are based on the presence of excessive tenderness on applying pressure to 11 of 18 specific muscle-tendon sites, appear to be about 85% sensitive and specific for fibromyalgia. Prevalence in the U.S. is about 2% (3.4% women, 0.5% men).

  A 2004 American Pain Society guideline advises a stepwise approach to the treatment of fibromyalgia, including early evaluation and treatment of comorbid conditions (e.g., mood and sleep disturbances), an exercise program, and cognitive behavior therapy. The recommended sequence of drug treatment corresponds to the strength of clinical evidence available to guideline authors. It includes an initial trial of a low-dose tricyclic antidepressant (TCA) or cyclobenzaprine (a muscle relaxant structurally similar to the TCAs), which are considered to be supported by strong clinical evidence, followed by subsequent trials of SSRIs, SNRIs, or tramadol (modest evidence), and possible consideration of combination therapy or use of an anticonvulsant. None of these medications are FDA-approved for the treatment of fibromyalgia; pregabalin is the first medication with this FDA indication.

  Clinical trials evaluating pregabalin for the treatment of fibromyalgia include four randomized controlled trials (RCTs) and three open-label studies (based on information supplied by the manufacturer). One 14-week trial (n = 1077) compared three doses of pregabalin (300, 450, or 600 mg/d) to placebo for 14 weeks, resulting in a significant reduction in the mean pain score of about 1 point on an 11-point scale (0-10) compared to placebo [300 mg/d -0.71; 450 mg/d -0.98; 600 mg/d -1.00]. Withdrawals due to adverse effects were substantially higher with pregabalin than placebo and appeared to be dose-related [300 mg/d 16%; 450 mg/d 22%, 600 mg/d 26%; placebo 12%). Pregabalin was also

compared to placebo in a 6-month randomized withdrawal study (n=566). Significantly more patients on placebo had lost clinical response at endpoint (61%) compared to those on pregabalin (32%). The other two trials consist of a 13-week RCT, which reported about a 0.7 point reduction in endpoint mean pain score with 600 mg/d of pregabalin, compared to placebo ($p<0.05$), and an 8-week trial comparing 150-, 300-, or 450 mg/d of pregabalin to placebo that showed a significant reduction in mean pain score only for the 450 mg/d dose. The latter was not included as part of the FDA approval process; it is the only trial currently published [Crofford et al, 2006].

A small (n=75) placebo-controlled 12-week RCT evaluating gabapentin (a formulary anticonvulsant medication similar to pregabalin) for the treatment of fibromyalgia was recently published [Arnold et al, 2006]. The trial reported significantly greater improvements with gabapentin (1200 – 2400 mg/d) than with placebo at endpoint; results were not inconsistent with those reported during pregabalin trials. However, given the size of the trial and the lack of any comparative evidence, there is probably insufficient evidence to draw any conclusion regarding the relative efficacy or safety of pregabalin or gabapentin for the treatment of fibromyalgia; more clinical evidence is available for pregabalin.

The P&T Committee agreed that pregabalin should be considered medically necessary for patients diagnosed with fibromyalgia based on established criteria (e.g., ACR criteria) who have failed an adequate trial, been unable to tolerate, or for whom treatment with TCAs or cyclobenzaprine is contraindicated or clinically inappropriate (e.g., due to potential cardiac effects).

Duloxetine for Fibromyalgia – Although duloxetine is not FDA-approved for fibromyalgia, its use is supported by two placebo-controlled RCTs [Arnold et al, 2004; Arnold et al, 2005]. Results are not inconsistent with those reported during pregabalin trials, although there is probably insufficient evidence to draw any conclusion regarding relative efficacy or safety of the two agents for the treatment of fibromyalgia. Duloxetine's therapeutic effect in fibromyalgia is most likely due to a distinctly different mechanism than pregabalin and likely includes effects on comorbid conditions, such as depression and anxiety, as well as pain.

Current MN criteria for duloxetine allow for its use in patients who have failed an adequate trial, been unable to tolerate, or for whom treatment with at least one medication from at least two of the following four drug classes is contraindicated or clinically inappropriate: TCAs (e.g., amitriptyline); tricyclic muscle relaxants (cyclobenzaprine); SSRIs (e.g., fluoxetine); or opioids (e.g., tramadol). The P&T Committee agreed that, given the evidence for pregabalin and its recent FDA approval for this indication, duloxetine MN criteria should be changed accordingly. At the same time, the P&T Committee agreed that SSRIs and opioids should be dropped from MN criteria due to inconsistent clinical evidence supporting the use of SSRIs for fibromyalgia and the overly broad definition of opioids. The P&T Committee agreed that duloxetine should be considered medically necessary for patients diagnosed with fibromyalgia based on established criteria (e.g., ACR criteria), who have failed an adequate trial, been

unable to tolerate, or for whom treatment with both TCAs or cyclobenzaprine AND pregabalin is contraindicated or clinically inappropriate.

F. Administration Action – Modification of Mecasermin PA Criteria – The PEC reported an administrative change to mecasermin PA criteria to remove references to mecasermin rinfabate (Iplex) following its withdrawal from the market due to the outcome of litigation. Increlex is now the only mecasermin product on the market. The manufacturer of Iplex will continue to develop it for non-short stature indications (e.g., myotonic muscular dystrophy, Lou Gehrig's disease, HIV-associated adipose redistribution syndrome, and retinopathy of prematurity), but it is likely to be some time before data are available.

G. Statin Budget Impact Analysis (BIA) Review – The P&T Committee reviewed the performance of the Antilipidemic-1 (LIP-1) budget impact model used to estimate the outcome of potential formulary scenarios. The review compared actual Military Health System (MHS) pharmaceutical expenditures to the predicted expenditures that were reported at the August 2006 P&T meeting for the LIP-1 drug class. Data were collected for two quarters following UF implementation in January 2007. The results were compared directly and reported as a percent deviation from the actual values.

Study results showed that the model performed adequately during the first two quarters following the implementation date. The largest departure from actual spending occurred at the military treatment facility (MTF) point of service primarily because of conservative assumptions made about the price of generic simvastatin. The analysis assumed modest reductions in price for simvastatin after generic entry but in actuality the price fell more rapidly then what was predicted. More data will be collected in the future to determine if model performance is sustained. Furthermore, several findings from this review will be incorporated into future budget impact models to improve the validity and reliability of model results.

5. REVIEW OF RECENTLY APPROVED AGENTS

A. Recently Approved Agents in Classes Not Yet Reviewed for the UF

The P&T Committee was briefed on four new drugs which were approved by the FDA (see Appendix B). The P&T Committee determined that these four new drugs fall into drug classes that have not yet been reviewed for UF status; therefore, UF consideration was deferred until drug class reviews are completed. The P&T Committee discussed the need for quantity limits (QLs) for budesonide/formoterol (Symbicort) oral inhaler, based on existing QLs for other oral inhalation products and recommendations for use in product labeling.

COMMITTEE ACTION: QUANTITY LIMITS

The P&T Committee voted (13 for, 0 opposed, 1 abstained, 3 absent) to recommend QLs for budesonide/formoterol of 1 inhaler per 30 days, 3 inhalers per 90 days.

B. Renin Angiotensin Antihypertensive – Aliskiren (Tekturna)

1) Aliskiren Relative Clinical Effectiveness – The DoD P&T Committee evaluated the clinical effectiveness of aliskiren, a new direct renin inhibitor. Aliskiren is classified as a renin angiotensin antihypertensive agent (RAA). The RAA drug

class was defined at the May 2007 DoD P&T Committee meeting, and includes the following categories of drugs:

- *Angiotensin Receptor Blockers (ARBs) - May 2007*
  - **UF/Basic Core Formulary (BCF)**: telmisartan (Micardis), telmisartan/ hydrochlorothiazide (HCTZ) (Micardis HCT)
  - **UF:** candesartan (Atacand), candesartan HCTZ (Atacand HCT), losartan (Cozaar), losartan/HCTZ (Hyzaar)
  - **Non-Formulary**: eprosartan (Teveten), eprosartan/HCTZ (Teveten HCT), irbesartan (Avapro), irbesartan/HCTZ (Avalide), olmesartan (Benicar), olmesartan/HCTZ (Benicar HCT), valsartan (Diovan), valsartan/HCTZ (Diovan HCT)
- *ARB/Calcium Channel Blockers – February 2006*
  - **UF/BCF:** benazepril/amlodipine (Lotrel, generics)
  - **Non-Formulary:** enalapril/felodipine (Lexxel), trandolapril/verapamil sustained release (Tarka)
- *Angiotensin Converting Enzyme (ACE) inhibitors – August 2005*
  - **UF/BCF:** lisinopril (Prinivil, Zestril, generics), lisinopril/HCTZ (Prinzide, Zestoretic, generics), and captopril (Capoten, generics)
  - **UF**: captopril/HCTZ (Capozide, generics), benazepril (Lotensin, generics), benazepril/HCTZ (Lotensin HCT, generics), enalapril (Vasotec, generics), enalapril/HCTZ (Vasoretic, generics), fosinopril (Monopril, generics), fosinopril/HCTZ (Monopril-HCT, generics), trandolapril (Mavik)
  - **Non-Formulary:** ramipril (Altace), quinapril (Accupril, generics), quinapril/HCTZ (Accuretic, generics), perindopril (Aceon), moexipril (Univasc, generics), moexipril/HCTZ (Uniretic, generics)

Pharmacology – Aliskiren is the first direct oral renin inhibitor marketed in the U.S. It decreases plasma renin activity and inhibits the conversion of angiotensinogen to angiotensin I. The correlation between decreased plasma renin activity and improved clinical outcomes is unclear.

Efficacy Measures – Clinical trials evaluating efficacy of aliskiren (typically 8 weeks in duration) have only assessed blood pressure (BP) reductions as the primary endpoint. Clinical trials have included patients with mild to moderate hypertension (mean diastolic BP 95-110 mm Hg); patients with severe hypertension have been excluded from clinical trials, along with patients with severe cardiac disease or renal impairment.

Efficacy Results – A pooled analysis from eight randomized trials reported mean reductions in seated BP with aliskiren 150 mg of 8.7-12/7.8-10.2 mm Hg and with aliskiren 300 mg of 14.1-15.9/10.3-12.3 mm Hg (not placebo adjusted). Aliskiren has been compared to ARBs (irbesartan, losartan and valsartan), diuretics (HCTZ) and the ACE inhibitor ramipril, as monotherapy and as combination therapy.

Overall, BP reductions with aliskiren were dose-related and were similar to that seen with the other drugs used as monotherapy; combination therapy produced additional BP reductions.

Outcomes Trials – Outcomes trials are currently underway, but results are not yet available. Trials are evaluating efficacy and safety of aliskiren in heart failure, post-myocardial infarction, diabetic nephropathy, left ventricular hypertrophy, diabetes, and metabolic syndrome. Initial results are expected in November 2007 for a study evaluating change in urinary albumin to creatinine ratio with aliskiren compared to losartan plus placebo (AVOID study) and a study evaluating reductions in brain natiuretic peptide in patients with hypertension and stable heart failure (ALOFT).

Safety – Available clinical data suggest that aliskiren most closely resembles an ARB in terms of adverse effects. Angioedema and hyperkalemia have been reported. Pooled data from clinical trials reported a discontinuation rate due to adverse effects of 2.2% with aliskiren vs. 3.5% with placebo. Dose-related diarrhea is the most common adverse effect. Clinically, aliskiren does not appear to inhibit or induce cytochrome P450 (CYP450) enzymes. Drug interactions have been reported with furosemide (decreased diuretic blood concentrations), and ketoconazole (increased aliskiren concentrations).

Place in Therapy – The exact place in therapy for aliskiren for treating hypertension is unknown at this time. Although aliskiren is indicated for use as monotherapy, it will likely be used as adjunctive therapy with other antihypertensive drugs (e.g., ACE inhibitors, ARBs, diuretics). A potential role for aliskiren would be in patients requiring double blockade of the renin-angiotensin aldosterone system; clinical trials with an ACE inhibitor plus an ARB in both heart failure and in patients with diabetic renal disease have suggested benefit; aliskiren could potentially be substituted for the ACE inhibitor in these settings.

Clinical Effectiveness Conclusion – The DoD P&T Committee concluded that:

a) Aliskiren is a new antihypertensive agent with a novel mechanism of action as a direct renin inhibitor.

b) Aliskiren's BP lowering effects are similar to those achieved with other antihypertensives, but it does not show improved efficacy compared to other classes of antihypertensive agents.

c) Combination therapy of aliskiren with ACE inhibitors, diuretics and ARBs has shown additive BP lowering effects compared to monotherapy with other antihypertensive agents.

d) Several other safe, once-daily, less costly antihypertensive drugs are available that have proven clinical outcomes (e.g., ACE inhibitors, ARBs, diuretics).

e) The long-term adverse event profile of aliskiren is unknown; diarrhea is the most commonly reported adverse event and the discontinuation rate is similar to placebo.

f) Clinical outcomes of aliskiren are unknown. Trials are underway, with initial results anticipated in November 2007.

The P&T Committee voted (14 for, 1 opposed, 0 abstained, 2 absent) to accept the clinical conclusions stated above. The one opposing vote was due to the opinion that there was insufficient clinical experience with aliskiren.

2) *Aliskiren Relative Cost Effectiveness* – The P&T Committee evaluated the relative cost effectiveness of aliskiren in relation to efficacy, safety, tolerability, and clinical outcomes of the other agents in the class, particularly the ARBs. Information considered by the P&T Committee included, but was not limited to, sources of information listed in 32 CFR 199.21(e)(2).

A cost minimization analysis (CMA) was employed to evaluate the cost effectiveness of aliskiren. The cost effectiveness of aliskiren was evaluated relative to ARBs, which were recently evaluated at the May 2007 DoD P&T Committee meeting.

The results of the CMA showed that the projected weighted average daily cost of aliskiren was higher than the weighted average daily cost of the ARBs designated as formulary on the UF.

Cost Effectiveness Conclusion – The P&T Committee concluded that:

> Although aliskiren was somewhat more costly relative to the ARBs designated as formulary on the UF, the P&T Committee was reluctant to designate aliskiren non-formulary at this time given its novel mechanism of action and the anticipated availability of clinical outcomes data that would enable the P&T Committee to more definitively asses its value relative to other antihypertensives.

The P&T Committee voted (14 for, 0 opposed, 1 abstained, 2 absent) to accept the cost effectiveness conclusions stated above.

3) *Aliskiren UF Recommendation*

Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of aliskiren, and other relevant factors, the P&T Committee, based upon its collective professional judgment, voted (10 for, 4 opposed, 1 abstained, 2 absent) to recommend that aliskiren be designated as formulary on the UF.

4) *Aliskiren MN Criteria* – Since aliskiren was not recommended for non-formulary status under the UF, establishment of MN criteria is not applicable.

5) *Aliskiren Implementation Plan* – Since aliskiren was not recommended for non-formulary status under the UF, establishment of an implementation plan is not applicable.

C. Nasal Corticosteroid – Fluticasone Furoate (Veramyst)

1) *Fluticasone Furoate Relative Clinical Effectiveness* – The P&T Committee reviewed the nasal corticosteroid drug class in November 2005. Nasal corticosteroids on the UF include fluticasone propionate (Flonase, generics),

mometasone furoate (Nasonex) and flunisolide (Nasarel). Fluticasone propionate is classified as the BCF agent. The non-formulary nasal corticosteroid agents are beclomethasone dipropionate (Beconase AQ, Vancenase AQ), budesonide (Rhinocort AQ), and triamcinolone (Nasacort AQ, Nasacort HFA).

Pharmacology – Fluticasone furoate is a new nasal corticosteroid marketed by GlaxoSmithKline, the manufacturer of fluticasone propionate, which has been available in a generic formulation since February 2006. Veramyst is structurally different from Flonase in that fluticasone propionate ester has been replaced with fluticasone furoate ester. Fluticasone furoate is active as the intact molecule and is not a prodrug or alternative salt of fluticasone. The structural change is responsible for higher glucocorticoid receptor binding affinity. However, *in vitro* claims of enhanced receptor binding have not translated into improved clinical effectiveness.

FDA-Approved Indications – Both fluticasone furoate and fluticasone propionate are FDA-approved for treating symptoms of seasonal allergic rhinitis (SAR) and perennial allergic rhinitis (PAR) in adults and children. Fluticasone furoate and mometasone are approved for use in children down to the age of 2 years, compared to 4 years with Flonase. In contrast to mometasone furoate, Veramyst is not currently approved for treatment of nasal polyps.

Efficacy – Efficacy assessment was based on the total nasal symptom score (TNSS), which was calculated based on the sum of a patient's score for four individual nasal symptoms (rhinorrhea, nasal congestion, sneezing, nasal itching). This was often reported as a reflective total nasal symptom score (rTNSS), which averages previous daytime and nighttime TNSSs over a certain time period.

Head-to-Head Trial-- There is insufficient evidence to determine if there are clinically relevant differences between fluticasone furoate and fluticasone propionate. One head-to-head trial in patients older than 12 years of age with SAR showed that fluticasone furoate was not inferior to fluticasone propionate in terms of changes from baseline in TNSS.

Placebo-Controlled Trials – FDA-approval of fluticasone furoate was based on six placebo-controlled trials.

a) In the trials enrolling adults with SAR (three studies) or PAR (one study), fluticasone furoate 110 mcg/day showed statistically significant improvement in rTNSS when compared to placebo.

b) In one study in children younger than 12 years with PAR, fluticasone furoate 55 mcg showed a statistically significant improvement in nasal symptom scores (rTNSS) compared to placebo; however there was no difference between placebo and Veramyst 110 mcg.

c) In the one pediatric study in patients with SAR, fluticasone furoate 110 mcg but not 55 mcg showed a statistically significant improvement in rTNSS compared to placebo.

Efficacy in Treating Ocular Symptoms – Nasal corticosteroids have not shown efficacy at reducing ocular symptoms of AR, in contrast to benefits seen with oral

antihistamines. With fluticasone furoate, although some improvements were noted in individual ocular symptoms evaluated as secondary endpoints (e.g., eye watering/tearing, eye itching/burning, and eye redness), there was no difference from placebo when reflective total ocular symptom score was evaluated as a primary endpoint.

Safety – The adverse event profile of fluticasone furoate is similar to other nasal corticosteroids. Common adverse events reported with fluticasone furoate included headache, epistaxis, and nasal ulceration. Administration of fluticasone furoate with ritonavir, a potent CYP3A4 inhibitor, is not recommended, due to the potential for increased systemic effects of fluticasone furoate.

Delivery Device – The Committee also evaluated differences in the delivery device, ease of administration, and particle size of fluticasone furoate compared to other nasal corticosteroids, but did not find a unique advantage or disadvantage relative to fluticasone propionate or mometasone furoate.

Clinical Effectiveness Conclusion – The DoD P&T Committee concluded that:

> Fluticasone furoate has no clinically significant differences with respect to safety, efficacy, or tolerability, when compared to other nasal corticosteroids included on the UF.

The P&T Committee voted (15 for, 0 opposed, 0 abstained, 2 absent) to accept the clinical effectiveness conclusion stated above.

2) *Fluticasone Furoate Relative Cost Effectiveness* – The P&T Committee evaluated the relative cost effectiveness of fluticasone furoate in relation to efficacy, safety, tolerability, and clinical outcomes of the other agents in the class. Information considered by the P&T Committee included, but was not limited to, sources of information listed in 32 CFR 199.21(e)(2).

   A CMA was employed to evaluate the cost effectiveness of fluticasone furoate relative to the UF nasal corticosteroids. The results of the CMA showed that the projected weighted average daily cost of fluticasone furoate was significantly higher than weighted average daily cost of the UF nasal corticosteroids.

   Cost Effectiveness Conclusion – The P&T Committee concluded that:

   > Fluticasone furoate was not cost effective relative to the UF nasal corticosteroids.

   The P&T Committee voted (12 for, 0 opposed, 1 abstained, 4 absent) to accept the cost effectiveness conclusion stated above

3) *Fluticasone Furoate UF Recommendation*

   Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of fluticasone furoate, and other relevant factors, the P&T Committee, based upon its collective professional judgment, voted (12 for, 0 opposed, 1 abstained, 4 absent) to recommend that fluticasone furoate be classified as non-formulary under the UF.

4) *Fluticasone Furoate MN Criteria* – Based on the clinical evaluation and the conditions for establishing MN for a non-formulary medication provided for in the UF rule, the P&T Committee recommended maintaining the medical necessity criteria previously established for the nasal corticosteroid class. The following general MN criteria will be applied for fluticasone furoate:

   1) The use of formulary alternatives is contraindicated.

   2) The patient has experienced significant adverse effects from formulary alternatives.

   3) Formulary alternatives have resulted in therapeutic failure.

   COMMITTEE ACTION: The P&T Committee voted (14 for, 0 opposed, 1 abstained, 2 absent) to approve the MN criteria outlined above.

5) *Fluticasone Furoate Implementation Plan* – There have been approximately 650 prescriptions for fluticasone furoate in the MHS, all in the TRICARE Retail Pharmacy Network (TRRx), since market introduction. The Committee discussed the merits of a 60-day implementation period. Additionally, Committee members directed that if operationally feasible, the $22 co-pay should start immediately upon signing of the minutes for new users; the $22 co-pay would go into effect after the 60-day implementation date for current Veramyst users.

   COMMITTEE ACTION: The P&T Committee voted (14 for, 0 opposed, 1 abstained, 2 absent) to recommend an effective date of the first Wednesday following a 60-day implementation period in the TMOP and TRRx, and at the MTFs no later than a 60-day implementation period. The implementation period will begin immediately following approval by the Director, TMA. If determined to be operationally feasible, the $22 co-pay would start immediately upon signing of the minutes for new users; the $22 co-pay would go into effect after the 60-day implementation date for current Veramyst users.

6) *Fluticasone Furoate QL* – The P&T Committee evaluated the need for QLs for fluticasone furoate. QLs are in effect for other nasal corticosteroids. Based on both adults and pediatric dosing in manufacturer labeling for fluticasone furoate, the number of doses in an inhaler (120 metered doses), and QLs for other nasal corticosteroids, the P&T Committee recommended QLs for fluticasone furoate.

   COMMITTEE ACTION: The P&T Committee, based upon its collective professional judgment, voted (14 for, 0 opposed, 1 abstained, 2 absent) to recommend QLs for fluticasone furoate in the TRRx for 1 inhaler device per 30 days and in the TMOP for 3 inhaler devices per 90 days.

6. DRUG CLASS REVIEW – NEWER ANTIHISTAMINES (NAs)

The P&T Committee evaluated the relative clinical effectiveness of the NA agents. The NA drug class includes the following agents (listed in order of FDA approval): loratadine (Claritin, generics), acrivastine/pseudoephedrine (Semprex-D), fexofenadine (Allegra, generics), cetirizine (Zyrtec), and desloratadine (Clarinex). The class also includes combinations of all of the single agent products with pseudoephedrine. Loratadine (Claritin, generics), cetirizine (Zyrtec), and desloratadine (Clarinex) are FDA-

indicated for the treatment of SAR, PAR, and chronic idiopathic urticaria (CIU). Fexofenadine is indicated for the treatment of SAR and CIU. Acrivastine/ pseudo-ephedrine is only indicated for the treatment of SAR.

All of the NAs are classified as inverse agonists of the H_1-receptor; they act to stabilize the H_1-receptor in its inactive conformation. Histamine is the main inflammatory mediator involved in the development of the majority of the symptoms seen in conditions treated with NAs.

As of June 2007, about three million MHS prescriptions for these agents were filled annually. The NA drug class was ranked #5 in terms of expenditures ($178 million) in FY 2006 . Across the MHS, cetirizine is the most commonly prescribed NA, followed by fexofenadine then loratadine. Usage of desloratadine and pseudoephedrine combination products is low and stable, while usage of acrivastine/pseudoephedrine is rare.

The brand-only agents are desloratadine, acrivastine/pseudoephedrine and cetirizine. Loratadine and fexofenadine are available as generics. Loratadine is only available over-the-counter (OTC). Brand-name cetirizine is expected to become available OTC by the end of 2007 and generic cetirizine OTC products are expected to be marketed in the first quarter of calendar year 2008. Marketing for the newly FDA approved product, levocetirizine (Xyzal), is expected to begin in September/October of 2007. Levocetirizine was not included in the current review; it will be addressed at a future meeting.

A. NAs – Relative Clinical Effectiveness

The P&T Committee evaluated the relative clinical effectiveness of the NAs currently marketed in the United States. Information regarding the safety, effectiveness, and clinical outcomes of these drugs was considered. The clinical review included, but was not limited to, the requirements stated in the UF Rule, 32 CFR 199.21(e)(1). The P&T Committee was advised that there is a statutory presumption that pharmaceutical agents in a therapeutic class are clinically effective and should be included on the UF, unless the P&T Committee finds by a majority vote that a pharmaceutical agent does not have a significant, clinically meaningful therapeutic advantage in terms of safety, effectiveness, or clinical outcome over the other pharmaceutical agents included on the UF in that therapeutic class.

Allergic rhinitis (AR) affects an estimated 20 to 40 million people in the United States. Multiple symptoms are associated with AR, including sneezing, itching, nasal congestion and rhinorrhea. These symptoms arise from different allergens comprised of pollens, molds, dust mites, and animal dander. Although AR is a term collectively used to define these symptoms, there are two different classifications, SAR or intermittent AR, and PAR or persistent AR.

SAR or “hay fever” is the rapid and reproducible onset and offset of symptoms in association with pollen exposure. PAR is more difficult to diagnose, because the symptoms of PAR overlap with symptoms of chronic sinusitis, upper respiratory infections and vasomotor rhinitis. Patients with PAR are affected with symptoms at least 9 months of a year. It is estimated that about 20% of the patients with AR suffer

from SAR, 40% from PAR, and 40% with both SAR and PAR (PAR with seasonal exacerbations).

CIU is defined as the occurrence of daily, or almost daily, wheals and itching for at least 6 weeks, with no obvious cause. CIU has not been the subject of detailed epidemiological studies. Published figures for frequency are confounded by uncertainty of the diagnosis, since the term "chronic idiopathic urticaria" is often taken to encompass physical urticarias. It has been estimated that about 0.1% of the population suffers from CIU, and 50% of these patients have symptoms for more than a year. Up to 20% of patients with symptoms greater than one year go on to have symptoms for 20 years or more. CIU is a major affliction causing serious disability.

1) *Efficacy*

The relative clinical effectiveness evaluation was based upon an evidence-based review of the clinical literature found in PubMed, Cochrane Library, National Guidelines Clearinghouse and reference lists of systematic review articles published through June 2007. In particular, this evaluation relied heavily upon the following sources: the Allergic Rhinitis and Its Impact on Asthma (ARIA) 2001 Guidelines and the draft 2007 update; the Agency for Healthcare Research and Quality 2002 Evidence and Technology Report/World Health Organization: Rhinitis; the European Dermatology Forum 2004 Consensus Statement: Urticaria; and the Oregon Drug Effectiveness Review Project (DERP) 2004 and 2006 Drug Class Review.

a) Seasonal Allergic Rhinitis

Adults

The Committee concluded that for the treatment of SAR in adults that there was insufficient evidence to suggest clinically significant differences in efficacy between fexofenadine, loratadine and cetirizine or desloratadine and fexofenadine. There is insufficient evidence to compare acrivastine/ pseudoephedrine to the other agents in the treatment of SAR.

Five head-to-head comparative trials assessed the efficacy of various NAs in the treatment of SAR in adults. The trials varied in country, season, and baseline characteristics of patients. These trials demonstrated no statistically significant difference between agents in total symptom score (TSS) change from baseline between cetirizine versus loratadine, cetirizine versus fexofenadine, or loratadine versus fexofenadine. The trials were too heterogeneous for meta-analysis. A recent head-to-head trial [Berger 2006] compared the efficacy of desloratadine and fexofenadine to placebo in patients with SAR. Results showed that both agents provided comparable efficacy, and were more effective than placebo. In the trial, subjects were randomized to desloratadine 5 mg, fexofenadine 180 mg once daily, or placebo. Mean daytime instantaneous TSS was significantly reduced from baseline by 28% with desloratadine, $p = 0.006$ and by 27% with fexofenadine, $p = 0.024$ versus placebo. The between agent mean TSS reduction was not statistically different ($p = 0.491$).

Children

There is insufficient evidence to suggest any clinical significant differences in efficacy in the treatment of SAR in children ≤ 12 years. There were no head-to-head comparative trials identified for children with SAR. Placebo and active controlled trials demonstrated that cetirizine, fexofenadine, and loratadine were more effective than placebo.

b) Perennial Allergic Rhinitis

Adults

The committee concluded that for the treatment of PAR in adults there is insufficient evidence to suggest clinically significant differences between the agents. Desloratadine has shown efficacy in the treatment of PAR in adults in a placebo-controlled trial, while loratadine has shown efficacy compared to placebo in an active-controlled trial that also included the older antihistamine clemastine. There were no head-to-head trials of sufficient quality identified for adults with PAR.

Children

There is insufficient evidence to suggest any clinically significant differences in efficacy in the treatment of PAR in children ≤ 12 years. There was one head-to-head comparative trial for loratadine versus cetirizine. The parent assessment results of this 4-week trial in 80 children, ages 2 to 6, showed cetirizine to be more effective than loratadine ($p < 0.001$) in relieving nasal symptoms associated with PAR. However, the global evaluation score by investigator showed no statistically significant difference. Placebo- and active-controlled trials for cetirizine and a placebo-controlled trial for loratadine showed the agents to be more effective than placebo in the treatment of PAR.

c) Chronic Idiopathic Urticaria

Adults

For CIU, the P&T Committee concluded that limited evidence suggests loratadine may be more effective than cetirizine and that cetirizine may be more effective than fexofenadine in adults.

Two fair quality head-to-head trials in adults with CIU were identified. One trial reported that loratadine 10 mg QD was more effective ($p<0.01$) in reducing TSS than cetirizine 10 mg QD or placebo [loratadine -81%, cetirizine -69%, placebo -55%]. There was no statistically significant difference in response rate between the two active agents [loratadine 63% vs. Cetirizine 45%, placebo 13%]. The other comparative trial reported that cetirizine 10 mg QD was more effective (p-value not reported) than fexofenadine 180 mg QD in symptom-free patients [cetirizine 51.9% vs. Fexofenadine 4.4%].

Children

Only cetirizine has evidence of efficacy for the treatment of CIU in children, based on both an active- and placebo-controlled trial.

2) *Safety / Tolerability*

As a class, the NAs are safe and well tolerated. There are few drug-drug interactions and clinical trial withdrawal rates are low (2 to 3%). The drugs can be used extensively in special populations.

Adverse Effects – While adverse effects with NAs occurred at a rate between 21 to 51% in clinical trials included in the 2006 DERP review, they tended to be minor, similar to placebo, and associated with a low discontinuation rate (2 to 3%). Minor adverse effects included stomach pain, lightheadedness, headache, and nausea.

Sedation – The NAs generally cause less drowsiness and sedation than older antihistamines. Cetirizine has been shown to cause more sedation than fexofenadine and loratadine. Loratadine and desloratadine, while causing minimal sedation at recommended dosages, have shown to cause significant sedation at higher doses. Fexofenadine has not shown sedation even in doses as high as 360 mg.

Cardiac arrhythmias – Cardiac toxicity has been a concern with NAs in the past, but does not appear to be a major issue with currently marketed products. Astemizole (Hismanal) and terfenadine (Seldane), two of the first newer antihistamines, were removed from the market because of their potential to cause prolonged QTc and torsade de pointes. However, newer second generation antihistamines have undergone extensive testing regarding their propensity to cause cardiac arrhythmias. Juniper et al (2005) reviewed these studies and concluded that cetirizine, fexofenadine and loratadine appear to have little potential to cause arrhythmias.

Pseudoephedrine-Containing Products – Combination products with pseudoephedrine can cause central nervous system stimulation, dizziness, weakness and insomnia. Pseudoephedrine has also been noted to cause palpitations as well as anxiety. Combination products containing pseudoephedrine are contraindicated in patients with narrow angle glaucoma, urinary retention, and with monoamine oxidase inhibitors (MAOIs). They should be used with *caution* in patients with hypertension, diabetes mellitus, ischemic heart disease, increased in ocular pressure, hyperthyroidism, renal impairment, and prostatic hypertrophy, and with *extreme* caution in patients with severe hypertension and/or severe coronary artery disease.

Use in Special Populations

- *Renal Failure* – All the NAs except acrivastine/pseudoephedrine have alternative dosing recommendations for patients with moderate to severe renal failure. Acrivastine/pseudoephedrine is not recommended in patients with a creatinine clearance less than or equal to 48 mL per minute.
- *Hepatic Failure* – Cetirizine, desloratadine, and loratadine have alternative dosing recommendations for patients with hepatic failure. Because

fexofenadine is metabolized to a very small extent, dosing changes in patients with hepatic failure is not necessary. The manufacturers of acrivastine/ pseudoephedrine have not made recommendations for alternative dosing of patients with hepatic failure.

- *Geriatrics* – There is insufficient data for manufacturers to make recommendations in populations greater than 70 years of age.
- *Pediatrics* – All the drugs, except acrivastine/pseudoephedrine and pseudoephedrine combination products, have indications for pediatric patients. Cetirizine, fexofenadine, and desloratadine have dosing recommendations for patients down to age 6 months. Loratadine has indications for patients to age 2 years and older.
- *Pregnancy and Lactation* – Acrivastine/pseudoephedrine, cetirizine and loratadine are FDA pregnancy category B. Although evidence from a randomized, controlled trial is not available, a cohort study of Israeli women showed no increase in major abnormalities of children born to women exposed to loratadine (RR 0.77; 95% CI 0.27 to 2.19) when compared to a no treatment control group. Secondary measures, including rate of still births, preterm deliveries and median birth weight, were similar between cohort groups. Desloratadine, fexofenadine and the combination products containing pseudoephedrine are FDA pregnancy category C.

  The manufacturer states that loratadine is compatible with breast-feeding. The manufacturers of other agents state that infant risk cannot be ruled out.

Drug Interactions

Drug interactions with ketoconazole and/or erythromycin have been reported with loratadine, desloratadine, and fexofenadine. However, despite the increased blood levels, there were no changes in QT interval, clinical condition, lab tests, or reported adverse events; dosage changes are not considered to be necessary. Antacids appear to reduce the area under the curve of fexofenadine by ~43%. Acrivastine/ pseudoephedrine and pseudoephedrine combination products can interact with antihypertensive drugs and reduce their antihypertensive effect. They should not be given within 14 days of a MAOI.

3) *Other Factors*

The NAs do not appear to differ significantly with regard to the availability of additional formulations, with the exception of acrivastine/pseudoephedrine. All the single agent products have multiple alternate dosage formulations (oral dissolving tablets, rapid dissolving tablets, solutions or suspensions) and combination products containing pseudoephedrine.

4) *Clinical Effectiveness Conclusion* – The P&T Committee concluded that:

a) Based on randomized placebo-controlled trials, cetirizine, desloratadine and loratadine are more efficacious than placebo for the symptomatic relief of SAR, PAR and CIU. Fexofenadine is more efficacious than placebo for the

symptomatic relief of SAR, and CIU. Acrivastine/pseudoephedrine is more efficacious than placebo for the symptomatic relief of SAR.

b) Based on six comparative trials in adults with SAR, there is insufficient evidence to suggest that there are clinically significant differences between cetirizine, fexofenadine, and loratadine, or desloratadine and fexofenadine. There is insufficient evidence to compare any of the agents in children less than 12 years old with this condition.

c) For the treatment of PAR in adults, there is insufficient evidence to suggest clinically significant differences between the agents. In children 2 to 6 years old, limited evidence based on one fair/poor quality comparative trial suggests that cetirizine may be more efficacious than loratadine with PAR.

d) For the treatment of CIU in adults, limited evidence based on two poor quality comparative trial suggests suggest that loratadine may be more efficacious than cetirizine for total symptom score reductions (but not response time), and cetirizine may be more efficacious than fexofenadine. In children, only cetirizine has evidence of efficacy for the treatment of CIU in children, based on both an active- and placebo-controlled trial.

e) The NAs appear to have similar adverse effect profiles and to result in similar low rates of discontinuation due to adverse events in clinical trials. There do not appear to be any major disadvantages for any one agent with respect to drug-drug interactions.

f) No NA appears preferable in hepatic impaired, renal impaired and pediatric patients. Loratadine, cetirizine and acrivastine/pseudoephedrine are FDA pregnancy category B, while desloratadine, fexofenadine and the combination products containing pseudoephedrine are FDA pregnancy category C.

g) All the parent products have multiple dosage forms and a pseudoephedrine-containing combination product.

h) It is likely that at one NA is sufficient for adequate clinical coverage, based on provider responses regarding prescribing practices and likely patient response.

i) Loratadine has been identified as a candidate drug for the DoD OTC Demonstration Program.

COMMITTEE ACTION: The P&T Committee voted (14 for, 0 opposed, 1 abstained, 2 absent) to accept the clinical effectiveness conclusions stated above.

B. NAs – Relative Cost Effectiveness

The P&T Committee evaluated the relative cost effectiveness of the NAs in relation to efficacy, safety, tolerability, and clinical outcomes of the other agents in the class. Information considered by the P&T Committee included, but was not limited to, sources of information listed in 32 CFR 199.21(e)(2).

The relative clinical effectiveness evaluation concluded that there was insufficient evidence to suggest that the NAs differed in regards to efficacy, safety, tolerability, or

clinical outcomes data. As a result, CMAs were performed to compare the relative cost effectiveness of the single agent NAs and the pseudoephedrine combinations. The CMAs compared the weighted average cost per day of treatment for each drug product across all three points of service.

Results from the NA CMAs showed that desloratadine and desloratadine/pseudoephedrine were not cost effective relative to the other agents in the newer antihistamine class. All other medications in the class were determined to be cost effective relative to their comparators.

Based on the results of the clinical review and the pharmacoeconomic evaluations, a BIA of various formulary scenarios was conducted to estimate the influence of other factors associated with a UF decision (i.e., market share migration, switch costs, non-formulary cost shares). The goal of the BIA was to aid the Committee in determining which group of NAs best met the majority of the clinical needs of the DOD population at the lowest expected cost to the MHS.

Cost Effectiveness Conclusion – The P&T Committee concluded that:

1) Desloratadine and desloratadine/pseudoephedrine were not cost effective relative to other comparable agents in the newer antihistamine class.
2) The UF scenario that designated desloratadine and desloratadine/pseudoephedrine as non-formulary under the UF was the most cost effective scenario.

COMMITTEE ACTION: The P&T Committee voted (15 for, 0 opposed, 0 abstained, 2 absent) to accept the cost effectiveness conclusion stated above.

C. NAs – UF Recommendations

COMMITTEE ACTION – In view of the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of the NAs, and other relevant factors, the P&T Committee, based upon its collective professional judgment, voted (14 for, 0 opposed, 1 abstained, and 2 absent) to recommend that:

1) Fexofenadine, fexofenadine/pseudoephedrine, cetirizine, cetirizine/pseudoephedrine, and acrivastine/pseudoephedrine should be maintained as formulary on the UF.
2) Desloratadine and desloratadine/pseudoephedrine should be classified as non-formulary under the UF.
3) Loratadine and loratadine/pseudoephedrine should be added to the UF for purposes of the TRICARE OTC Demonstration Program.
4) At such time as cetirizine and cetirizine/pseudoephedrine are made available over-the-counter, both products should be maintained on the UF for purposes of the TRICARE OTC Demonstration Program.
5) Desloratadine and desloratadine/pseudoephedrine should be reclassified as generic on the UF when the generic products are available and cost effective relative to similar agents in the newer antihistamine class.

D. NAs – MN Criteria

Based on the clinical evaluation and the conditions for establishing MN for a non-formulary medication provided for in the UF rule, the P&T Committee recommended the following general MN criteria for desloratadine and desloratadine/pseudo-ephedrine:

1) The use of formulary alternatives is contraindicated.
2) The patient has experienced significant adverse effects from formulary alternatives.
3) Formulary alternatives have resulted in therapeutic failure.

The P&T Committee noted that acrivastine/pseudoephedrine, like other NA combination products with pseudoephedrine, is not indicated in children younger than 12 years of age.

COMMITTEE ACTION: The P&T Committee voted (14 for, 0 opposed, 1 abstained, 2 absent) to approve the MN criteria outlined above.

E. NAs – UF Implementation Period

The P&T Committee recommended an effective date of the first Wednesday following a 90-day implementation period in the TRICARE Mail Order Pharmacy (TMOP) program and TRRx, and at the MTFs no later than a 90-day implementation period. The implementation period will begin immediately following approval by the Director, TMA

MTFs will not be allowed to have desloratadine and desloratadine/pseudoephedrine on their local formularies. MTFs will be able to fill non-formulary requests for these agents only if both of the following conditions are met: 1) the prescription must be written by a MTF provider, and 2) MN is established. MTFs may (but are not required to) fill a prescription for a non-formulary NA agent written by a non-MTF provider to whom the patient was referred, as long as MN has been established.

COMMITTEE ACTION: The P&T Committee recommended (14 for, 0 opposed, 1 abstained, 2 absent) an effective date of the first Wednesday following a 90-day implementation period in the TMOP and TRRx, and at the MTFs no later than a 90-day implementation period. The implementation period will begin immediately following the approval by the Director, TMA.

F. NAs – BCF Review and Recommendations – The P&T Committee considered the BCF status of the NA agents. Based on the results of the clinical and economic evaluations presented, the P&T Committee voted (14 for, 0 opposed, 1 abstained, and 2 absent) to recommend that the current BCF listing for this class be maintained, requiring each MTF to carry at least one single-ingredient agent from the newer antihistamine class (loratadine, cetirizine, or fexofenadine) on their local formulary, including at least one dosage form suitable for pediatric use. The P&T Committee noted that loratadine is the most cost effective NA in the MTFs, at approximately 1/12 the cost of the next most competitively priced agent.

7. DRUG CLASS REVIEW – LEUKOTRIENE MODIFIERS (LMs)

The P&T Committee evaluated the relative clinical effectiveness of the LMs. The LM class is comprised of two leukotriene receptor antagonists, montelukast (Singulair) and zafirlukast (Accolate); and one 5-lipoxygenase inhibitor, zileuton (Zyflo). A controlled release formulation of zileuton (Zyflo CR) has been approved by the FDA, but is not yet commercially available and was not included in the review.

Currently montelukast is the only BCF LM agent. None are available in a generic formulation. The LM drug class accounted for $101 million dollars in MHS expenditures in FY 2006, and is ranked #16 in terms of total expenditures during that time period. Over 97% of the utilization is for montelukast; from June 2006 to May 2007, there were over 300,000 montelukast utilizers in the MHS, over 3,000 zafirlukast utilizers and only 300 zileuton utilizers.

A. LMs – Relative Clinical Effectiveness

The P&T Committee evaluated the relative clinical effectiveness of the LMs marketed in the U.S. By considering information regarding their safety, effectiveness and clinical outcomes. The clinical review included consideration of pertinent information from a variety of sources determined by the P&T Committee to be relevant and reliable, including but not limited to sources of information listed in 32 CFR 199.21(e)(1).

1) *FDA-approved indications*

a) Asthma

Montelukast, zafirlukast and zileuton are all indicated for the treatment of asthma in adults and children. Montelukast is approved in children as young as one year of age, zafirlukast is indicated in children down to age of six years, and zileuton is approved for use in children aged 12 years and older. The LMs are most often used as adjunctive therapy to first-line asthma therapies including inhaled corticosteroids (ICSs) and long-acting beta agonists (LABAs).

b) SAR and PAR

Montelukast is the only LM with indications other than asthma; it is FDA-approved for treating allergic rhinitis in adults and children. For SAR, montelukast is approved down to the age of two years, and for PAR down to the age of six months.

c) Exercise-Induced Bronchoconstriction (EIB)

In April 2007, montelukast received approval for use in EIB in patients older than 15 years of age.

2) Efficacy

a) Asthma

i) National guidelines – The National Heart, Lung and Blood Institute's (NHLBI) National Asthma Education Prevention Program (NAEPP)

guidelines state that LMs are not first-line therapy. For all age groups, ICSs are considered first-line. In adolescents older than 12 years and adults, LABAs are preferred over LMs for adjunctive therapy; in this age group zileuton is an alternative, but not preferred therapy due to limited efficacy data and requirements for liver function test (LFT) monitoring. For younger children, LMs are an alternative based on the convenience of delivery device (oral administration vs. Nebulizer or oral inhaler) and safety data, rather than efficacy data.

ii) Meta-Analyses and Systematic Reviews – Three meta-analyses evaluated efficacy of the LMs compared with other asthma controller therapies.

- Sin et al (JAMA 2004) found that LMs were less effective than ICSs in reducing asthma exacerbations and improving forced expiratory volume in 1 second (FEV1) (RR 1.72; 95% CI 1.28-2.31).
- ICSs were also preferred in a Cochrane review (Ducharme, DiSilva) where patients taking LMs versus those taking ICSs were approximately 60%-70% more likely to have an asthma exacerbation (RR 1.65; 95% CI 1.36-2.0). Other endpoints such as FEV1 improvements, withdrawal rates from therapy due to poor symptom control, and asthma symptoms scores were consistently more favorable with ICSs.
- A second Cochrane review (Ducharme, Kakauma) that compared the combination of LMs to ICS versus ICS alone demonstrated minimal differences in combination therapy versus monotherapy (e.g., decreased need for albuterol by only one puff per week and no change in steroid dose vs. using the ICS alone). The combination of LABA plus ICS was superior in preventing asthma exacerbations requiring oral steroids than the combination of LM plus ICS.

iii) Clinical Trials – There are no head–to-head clinical trials evaluating the LMs for asthma. Results of placebo controlled trials or trials using ICS as an active comparator show that all three LMs produced statistically significant changes in FEV1, peak expiratory flow, and asthma symptoms score, compared to placebo. Indirect comparisons of placebo-controlled trials with similar study design using montelukast and zafirlukast suggest similar effects on asthma control, based on increases in FEV1 and as-needed beta agonist use. Fewer studies are available with zileuton.

iv) Steroid-Sparing Effects –Whether the LMs allow a reduction in ICS dose is controversial. The product labeling for montelukast states that a lower dose of ICS than previously used was able to control asthma symptoms when the LM was added on to ICS in one study in 226 patients. The Ducharme/Kakauma Cochrane analysis found no effect on steroid dose when a LM was added on to ICS. There is insufficient evidence to determine the steroid sparing effects of zafirlukast and zileuton. NHLBI/ NAEPP guidelines caution that the steroid sparing effects of the LMs are inconclusive, and that patients cannot be entirely weaned from the ICS.

b) *Exercise Induced Bronchoconstriction*

i) *National Guidelines* – NHLBI/NAEPP guidelines for EIB consider albuterol as the drug of choice, as albuterol prevents EIB in more than 80% of patients and is backed by good quality (Level A) evidence. Similar efficacy rates are seen with the LABAs (also considered Level A evidence); however, caution is required as tolerance develops with chronic use. In contrast, montelukast attenuates EIB in 50% of patients and is supported by Level B evidence. The guidelines stress that EIB is frequently a marker of inadequate asthma management, and that prevention and improved asthma control are recommended.

ii) *Clinical Trials* – Montelukast received FDA approval for EIB in patients older than 15 years in April 07 based on a placebo controlled trial showing a statistically significant benefit 2 hours after dosing. Montelukast has an onset of action of 1-2 hours, and a duration of action lasting up to 24 hours. There are no head-to-head trials comparing montelukast with albuterol. Two comparative trials with montelukast and salmeterol (Serevent) showed similar efficacy at preventing EIB within one hour prior to exercise. One study has evaluated efficacy of zileuton for EIB, but it is not approved by the FDA for this use.

c) *Allergic Rhinitis*

i) *Efficacy Measures* - Meta-analyses and clinical trials evaluating treatment for AR most frequently used two efficacy measures; variations of the rhinitis symptom score where the severity of nasal symptoms of congestion, itching, rhinorrhea are assessed, and the rhinoconjunctivitis-specific quality of life (RQLQ).

ii) *National Guidelines* – A preview of the updated Allergic Rhinitis in Asthma (ARIA) guidelines from the World Health Organization lists NAs or nasal corticosteroids (NCS) as first-line therapy for mild AR; the combination of a NA and NCS for moderate AR; and the combination of NA and NCS plus a LM for severe AR.

iii) *Meta-Analyses and Systematic Reviews* - Two meta-analyses have evaluated efficacy of the LMs vs. NCS and NAs for SAR; one by Wilson et al (2004) and the other by Rodrigo et al (2006).

- *LM vs. Placebo* – The Wilson meta-analysis included eight RCTs (one with zafirlukast; 7 with montelukast; over 3,900 patients) comparing a LM either alone or in combination with NAs or NCS vs. placebo or other treatments. The LMs significantly improved the nasal symptom score 5% more than placebo (95% CI 3-7%). This was of questionable clinical significance, as the authors used a 10% change as designating a minimally important result. There is no one recognized minimally important change in nasal score.

  The four studies where RQLQ was evaluated found that the LM significantly improved RQLQ by 0.3 units compared with placebo

(95% CI 0.24 to 0.36). A minimally important change in RQLQ is accepted to be a change of at least 0.57 units.

- *LM vs. NAs* – The treatment efficacy of LMs vs. NAs was compared in both the Wilson (4 RCTs) and Rodrigo (5 RCTs) meta-analyses. The trials included all compared montelukast with loratadine. In the Wilson analysis, loratadine improved nasal symptom score 2% more than montelukast, but the results were not statistically significant (95% CI 0% to 4%). Treatment with loratadine significantly improved RQLQ by 0.11 units more than montelukast (95% CI 0.04 to 0.18 units). The Rodrigo meta-analysis found no statistically significant difference between montelukast and loratadine in nasal symptom score or RQLQ; additionally, when individual eye symptoms were scored, there was no significant difference between montelukast and loratadine.
- *LM vs. NCS* – In the Wilson meta-analysis, montelukast was compared with fluticasone (3 RCTs), mometasone (1 RCT), budesonide (1 RCT), and zafirlukast was compared with beclomethasone (1 RCT). NCS improved nasal symptom score 12% more than the LM (95% CI 5% to 18%); RQLQ was not assessed.
- *LM plus NA vs. NCS* – The Rodrigo meta-analysis evaluated the combination of LM with a NA vs. NCS. Overall there were only minimal differences noted, although there was a trend toward superiority of the NCS.

iv) PAR – There are no meta-analyses evaluating LM efficacy for PAR. Montelukast is the only LM approved for PAR, which was supported by one placebo-controlled trial in over 1,900 patients that showed statistically significant improvements in daytime and nighttime symptom scores, RQLQ scores, and provider and patient global assessment.

In the pediatric population, montelukast is approved for use in SAR in children age two years and older, and for PAR in age 6 months and older. However, published clinical trial data is limited in the pediatric population, and is primarily based on safety. In two studies in children with PAR, montelukast was less efficacious than cetirizine in most of the endpoints studied.

v) Pediatric Issues

- *FDA Labeling* – Although montelukast is approved for patients as young as 6 months with PAR, and as young as 2 years with SAR, the product labeling states that efficacy data is extrapolated from studies with adolescents older than 15 years with AR.
- *Clinical Trials* – Two small placebo-controlled studies evaluated montelukast with cetirizine in Taiwanese children ranging in age from 2-6 years and 6-12 years with PAR. Cetirizine was statistically

significantly superior to montelukast in improving total nasal symptoms and the individual symptom of nasal congestion.

- *National Guidelines* – The ARIA guidelines for children recommend following the same principles as adults. They acknowledge that NCS are the most effective treatment of pediatric AR, but recognize that long-term safety remains controversial for growth suppression and hypothalamic-pituitary axis suppression.
- *Other Treatments* – Other treatments for AR are approved for use in children as young as 6 months (cetirizine, fexofenadine, and desloratadine), two years (loratadine and mometasone), and 4 years (fluticasone propionate).

d) Off-Label Uses

The Committee reviewed several off-label uses for the LMs; most of these lack sufficient data to prove safe and efficacious use at this time. Treatment of nasal polyps and treatment of reactive airways disease after acute respiratory syncytial virus illness in children appear to have sufficient published evidence to prove safe and clinically effective.

3) *Safety and Tolerability*

a) Serious Adverse Effects

i) Churg-Strauss Syndrome – Case reports of montelukast and zafirlukast causing systemic eosinophilic vasculitis in patients with asthma and AR are available. However, it is uncertain whether this is a direct effect of the LM or due to concomitant withdrawal of corticosteroids. There is insufficient evidence to determine whether one LM is more likely than another to cause this syndrome.

ii) Hepatotoxicity

- *Montelukast* – The product labeling states there are rare reports of hepatic injury without increases in LFTs. The incidence of in aspartate aminotransferase (AST) elevations is 1.7% with montelukast vs. 1.2% with placebo.
- *Zafirlukast* – Product labeling describes rare reports of hepatic failure, with resolution of symptoms and LFT elevations upon drug discontinuation; there is no requirement in labeling for LFT monitoring. According to the manufacturer, there have been eight published cases linking zafirlukast with hepatic failure, two of which required transplant. Information received in response to a Freedom of Information Act request to the FDA revealed 66 cases of hepatitis or liver failure and 23 deaths between 1997 and 2002. These cases were spontaneous reports, and a direct causality with zafirlukast has not been assessed.
- *Zileuton* – Use is contraindicated in patients with active hepatic disease of LFT elevations greater than 3 the upper limit of normal

(ULN). In clinical trials of over 5,000 patients, the incidence of AST elevations more than 3 times the ULN was 4.6% with zileuton. LFT monitoring is required at baseline, monthly for the initial three months of treatment, and every 2-3 months thereafter.

b) Minor Adverse Effects – Overall the LMs have a low incidence of minor adverse effects, with headache and gastrointestinal complaints reported most commonly. Pooled data from the product labeling suggests that there is no relevant difference between the LMs in minor adverse effects.

c) Drug-Drug Interactions – Montelukast has not been associated with clinically significant drug interactions. Zafirlukast and zileuton both can increase the prothrombin time when administered with warfarin (Coumadin). Zileuton can decrease theophylline metabolism, leading to increased theophylline concentrations; theophylline dosage reductions of 50% are required with concomitant use.

d) Special Populations – Montelukast is rated pregnancy category B, while both zafirlukast and zileuton are rated pregnancy category C. Dosage adjustments in renal impairment are not necessary with the LMs. Zileuton is contra-indicated for use in patients with active liver disease.

4) *Other Factors*

Montelukast is available in several dosage formulations (tablets, chewable tablet, and granules), and is dosed once daily. Zafirlukast requires BID dosing, while zileuton requires QID dosing.

5) *Therapeutic Interchangeability*

There is a low degree of therapeutic interchangeability between the three LMs. Montelukast has advantages in terms of multiple indications, multiple formulations, a more favorable safety profile, and FDA approval in the pediatric population.

6) *Clinical Coverage*

To meet the needs of MHS patients, one LM is required; however, it must have a favorable safety profile. For EIB, availability of montelukast, the only LM approved for this indication, is less urgent, due to efficacy and acceptance of albuterol and LABA.

7) *Overall Clinical Effectiveness Conclusion* – The P&T Committee concluded that:

a) For the treatment of asthma, NHLBI/NAEPP guidelines include LMs as alternative, but not preferred therapy. LMs are more effective than placebo in controlling asthma symptoms, but are less effective than ICS, and are less effective when added on to LABA vs. use of a LABA with ICS. Addition of a LM to ICS provides modest benefit over use of the ICS as monotherapy.

b) In placebo-controlled trials for asthma, the three LMs montelukast, zafirlukast, and zileuton demonstrate clinical effectiveness in endpoints such as reduction in exacerbations, improvements in FEV1, asthma symptoms

scores and short acting beta-agonist use. There is insufficient evidence to determine whether one LM is more efficacious at controlling asthma symptoms than another.

c) Limited evidence suggests that LMs may permit a reduced inhaled steroid dose, or could be used in patients resistant or unable to tolerate ICS. The extent or clinical significance of this "steroid sparing" effect is uncertain.

d) Montelukast is the only LM that is FDA approved for the treatment of AR, and is specifically approved for both SAR and PAR. There are a few small clinical trials that evaluate zafirlukast in the treatment of AR, but they fail to consistently show efficacy. There is no data to support the use of zileuton in AR.

e) For AR, meta-analyses show that LMs are superior to placebo in clinically relevant AR endpoints such as rhinitis symptoms scores and rhinoconjunctivitis quality of life scores; however, the treatment effect is modest. When compared to antihistamines, the LMs show relatively similar efficacy. NCSs are clinically superior to montelukast in all clinical endpoints studied. Combinations of an LM with an antihistamine is modestly more effective than either agent alone, but not superior to NCS in improving nasal symptoms of AR.

j) In the pediatric population, montelukast is approved for use in SAR in children age two years and older, and for PAR in age 6 months and older. However, published clinical trial data is limited in the pediatric population, and is primarily based on safety. In two studies in children with PAR, montelukast was less efficacious than cetirizine in most of the endpoints studied.

k) In regard to safety and tolerability, zileuton has been associated with hepatotoxicity, requires LFT monitoring, and is contraindicated in patients with active liver disease. Zafirlukast has also been associated with hepatotoxicity including liver failure and death; however, this data is from spontaneously reported adverse events reports and must be interpreted cautiously. Zafirlukast and zileuton are associated with more clinically significant drug interactions than montelukast.

l) In regard to other factors, montelukast has the advantage of a greater number of FDA approved indications, pediatric indications, less frequent dosing (once daily versus twice and four-times daily for zafirlukast and zileuton), and availability of alternative dosage formulations.

m) Overall, based on clinical issues alone, montelukast is preferred over zafirlukast, which in turn is preferred over zileuton.

COMMITTEE ACTION: The P&T Committee voted (14 for, 0 opposed, 0 abstained, 3 absent) to accept the clinical effectiveness conclusions stated above.

B. LMs – Relative Cost Effectiveness

The P&T Committee evaluated the relative cost effectiveness of the LM agents in relation to efficacy, safety, tolerability, and clinical outcomes of the other agents in the class. Information considered by the P&T Committee included, but was not limited to, sources of information listed in 32 CFR 199.21(e)(2).

The relative clinical effectiveness evaluation determined that there was enough evidence to show that the LM medications differed in regards to efficacy and safety in the treatment of asthma, AR, and EIB. Moreover, the clinical review concluded that the LMs have a role in the management of asthma and are gaining acceptance in the treatment of EIB. However, the use of LMs in AR remains controversial. As a result, the pharmacoeconomic analysis first compared the LMs in a CMA to gauge the cost effectiveness of the agents within the LM class. Once complete, the analysis then considered the cost effectiveness of LMs as compared to NAs and NCS in the treatment of AR. Each analysis compared the weighted average cost per day of treatment across all three points of service.

Results from the LM CMA showed that zafirlukast was the least costly agent in the class. In comparison, montelukast was more costly per day of treatment but also provided additional indications, a better adverse event profile, multiple dosage forms, and more evidence in pediatrics than the other agents in the class. The least cost effective product was zileuton.

In the treatment of AR, the cost effectiveness analysis showed that NA agents and NCS agents were the most cost effective options for the treatment of AR. The LMs were less effective than the NCS and provided comparable efficacy to the NAs. However, the LMs were significantly more costly per day of treatment than either the NAs or the NCS agents. Hence, pervasive use of LMs as first-line therapy in AR should be discouraged to optimize treatment of AR in the MHS.

Based on the results of the clinical review and the pharmacoeconomic evaluations, a BIA of a UF scenario that required a step therapy/PA program for use of LMs in allergic rhinitis (with no PA for other indications) was compared to a scenario with no PA required for use of LMs in any indication. The analysis was conducted to estimate the influence of other factors associated with a UF decision (i.e., market share migration, switch costs, non-formulary cost shares). The goal of the BIA was to estimate the impact of enacting a step therapy/PA policy for AR in the LM class and to aid the Committee in determining which group of LMs best met the clinical needs of the majority of the DOD population at the lowest expected cost to the MHS.

Cost Effectiveness Conclusion – The P&T Committee concluded that:

1) Zafirlukast was the least costly agent in the class; montelukast was more costly relative to zafirlukast but provided additional indications, a better adverse event profile, multiple dosage forms, and more evidence in pediatrics than the other agents in the class; zileuton was not cost effective relative to the other products.
2) LMs are not cost effective in the treatment of AR relative to antihistamines and NCS agents and should not be considered as first-line therapy in the treatment of AR.

3) The Committee concluded that the UF scenario that placed zafirlukast and montelukast on formulary with a step therapy/PA required for use in AR was the scenario that resulted in the lowest expected expenditures in the LM class.

COMMITTEE ACTION: The DOD P&T Committee voted (14 for, 0 opposed, 1 abstained, and 2 absent) to accept the LM relative cost effectiveness analysis as presented by the PEC.

C. LMs – Step Therapy Consideration

For SAR and PAR (although montelukast is the only LM with this indication) the LMs are considered third-line agents after antihistamines and NCS. The Committee reviewed several programs utilized by civilian health plans to address use of the LMs for AR. Several plans allow unrestricted use of the LMs for asthma, but require PA for AR, primarily based on previous use of an antihistamine and/or NCS.

The Committee considered a step therapy/PA program where LMs would be allowed for MHS patients with asthma, but PA would be required for LM use in AR patients older than 5 years of age. Patients older than the age of 5 would require prior use of a NA and NCS, before LM use would be allowed.

COMMITTEE ACTION: Although the committee agreed that the LMs are not cost effective for AR, the Committee voted (6 for, 8 opposed, 1 abstained, and 2 absent) against enacting a step therapy/PA policy for use of LMs in the management of AR. Similar policies have recently been initiated with other drug classes in the MHS and the Committee felt that the most prudent course of action at this time was to delay enacting another step therapy/PA policy. Instead, the PEC will gather additional evidence about the effect of the other step therapy/PA policies recently implemented in the MHS while educating MTF providers to minimize the use of LMs for the management of AR. The PEC will also monitor utilization in the LM class. If the use of LMs for AR continues to proliferate, the Committee will review the class again to determine if further action is required.

D. LMs – UF Recommendations

COMMITTEE ACTION – In view of the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of the LMs, and other relevant factors, the P&T Committee, based upon its collective professional judgment, voted (14 for, 0 opposed, 1 abstained, and 2 absent) to recommend that zafirlukast and montelukast be maintained as formulary on the UF and that zileuton be classified as non-formulary under the UF.

E. LMs – MN Criteria

Based on the clinical evaluation for zileuton, and the conditions for establishing MN for a non-formulary medication provided for in the UF rule, the P&T Committee recommended the following general MN criteria for zileuton:

1) Use of formulary alternatives is contraindicated.
2) The patient has experienced significant adverse effects from formulary alternatives.

3) Formulary agents have resulted in therapeutic failure.

4) Patient previously responded to non-formulary agent and changing to a formulary agent would incur unacceptable risk.

With respect to criterion #4, the P&T Committee's primary concern was for asthma patients stabilized on zileuton, although this is likely to apply to very few patients considering the low usage of zileuton.

COMMITTEE ACTION: The P&T Committee voted (14 for, 0 opposed, 1 abstained, 2 absent) to approve the MN criteria outlined above.

F. LMs – UF Implementation Period

Approximately 145 beneficiaries (0.07% of those using agents in the LM class) will be affected by the UF decision. The P&T Committee recommended an effective date of the first Wednesday following a 90-day implementation period at the TMOP and TRRx, and at the MTFs no later than a 90-day implementation period. The implementation period will begin immediately following approval by the Director, TMA.

MTFs will not be allowed to have zileuton on their local formularies. MTFs will be able to fill non-formulary requests for zileuton only if both of the following conditions are met: 1) the prescription must be written by a MTF provider, and 2) MN is established. MTFs may (but are not required to) fill a prescription for a non-formulary LM agent written by a non-MTF provider to whom the patient was referred, as long as MN has been established.

COMMITTEE ACTION: The P&T Committee recommended (13 for, 1 opposed, 1 abstained, 2 absent) an effective date of the first Wednesday following a 90-day implementation period at the TMOP and TRRx, and at the MTFs no later than a 90-day implementation period. The implementation period will begin immediately following the approval by the Director, TMA.

G. LMs – BCF Review and Recommendation

The P&T Committee considered the BCF status of the LM agents. Based on the results of the clinical and economic evaluations presented, the P&T Committee voted (13 for, 1 opposed, 1 abstained, and 2 absent) to recommend that montelukast be retained on the BCF (specific formulations include tablets, chewable tablets, and oral granules).

8. DRUG CLASS REVIEW – GROWTH STIMULATING AGENTS (GSAs)

The P&T Committee evaluated the relative clinical effectiveness of the GSAs. This class is divided into two subclasses: growth hormone (GH) agents (somatropin products) and insulin-like growth factor-1 (IGF-1) agents (mecasermin). The GSA drug class accounted for about $23 million in MHS expenditures in FY 2006.

A. GSAs – Relative Clinical Effectiveness

The P&T Committee evaluated the relative clinical effectiveness of the GSA agents currently marketed in the U.S. Information regarding the safety, effectiveness, and clinical outcomes of these drugs was considered. The clinical review included, but

was not limited to, the requirements stated in the UF Rule, 32 CFR 199.21(e)(1). The P&T Committee was advised that there is a statutory presumption that pharmaceutical agents in a therapeutic class are clinically effective and should be included on the UF, unless the P&T Committee finds by a majority vote that a pharmaceutical agent does not have a significant, clinically meaningful therapeutic advantage in terms of safety, effectiveness, or clinical outcome over the other pharmaceutical agents included on the UF in that therapeutic class.

Table 1: Growth Stimulating Agents Available in the U.S.

Subclass	Generic Name	Brand Name	FDA Indication
Growth Hormone	Somatropin	Genotropin (Pfizer) Genotropin Miniquick	GHD, PWS, TS, SGA
		Humatrope (Eli Lilly)	GHD, TS, ISS, SHOX
		Nutropin (Genentech) Nutropin AQ	GHD, TS, CRI, ISS
		Norditropin (Novo Nordisk) Norditropin Nordiflex	GHD, Noonan's Syndrome
		Omnitrope (Sandoz)	GHD
		Saizen (Serono)	GHD
		Serostim (Serono)	AIDS/HIV wasting
		Tev-Tropin (Teva/Gate)	GHD (pediatric patients only)
		Zorbtive (Serono)	SBS
Insulin-like growth factor (IGF-1)	Mecasermin	Increlex (Tercica)*	IGFD

*A second mecasermin product, mecasermin rinfabate (Iplex; Insmed) has been withdrawn from the market due to patent litigation settlement; the manufacturer continues to develop the product for the treatment of non-growth related conditions.

GHD = Growth Hormone Deficiency; PWS = Prader-Willi Syndrome; TS = Turner Syndrome; SGA = Small for Gestational Age; ISS = Idiopathic Short Stature; SHOX = Short Stature Homeobox gene deficiency; CRI = Chronic Renal Insufficiency; SBS = Short Bowel Syndrome; IGFD = Insulin-like Growth Factor Deficiency

1) Background

a) Growth stimulant agents

i) Products

This class of drugs includes only two molecular entities, somatropin and mecasermin. There are multiple competing somatropin products. The majority of these are indicated for the treatment of GH deficiency (GHD), which is the most common use, although manufacturers are constantly researching additional FDA indications. Mecasermin is an orphan drug approved by the FDA in 2005 to treat severe primary insulin-like growth factor deficiency (IGFD), which affects a very small number of patients (about 6,000 in the United States).

ii) FDA Approval process

At present, the FDA has no mechanism for approving "generic" versions of biologic drugs (large-molecule or complex proteins that are synthetic or recombinant versions of natural biological substances), which are

regulated under Section 351 of the Public Health Service Act. The lack of a mechanism for approval of generic biologic products produces a unique situation in this class, with multiple competitive branded products available.

iii) Off-Label Uses

GH has the potential for substantial off-label use. It has been proposed as an anti-aging medication based on its effect on growth and metabolism. However, a systematic review found little evidence that GH is clinically beneficial in healthy elderly patients and substantial evidence suggesting high adverse event rates. The data did not support improvements in bone mineral density, lipid levels, or fasting glucose and insulin levels.

2) Efficacy

a) Efficacy Measures

The following measures are used as efficacy trial endpoints for both somatropin and mecasermin in growth-related condition:

- *Height expressed in centimeter (cm) or inches (in):* Absolute or change from baseline
- *Standard Deviation Score (SDS):* Actual height minus mean height for age divided by the standard deviation of height for age. The normal population mean is zero; a normal SD score will lie between -2 SD and +2 SD.
- *Final height:* Stipulates that the individual has stopped growing based on 1) the growth rate has slowed to less than 1-2 cm/year or 2) epiphyseal closure has occurred as confirmed by radiography
- *Near final height:* Based on height velocity less than a certain value, chronological age greater than 15-17 years, or skeletal age greater than 14-16 years
- *Height velocity:* Growth per period of time
- *Mid-parental height:* For boys, add 2.5 in or 6.5 cm to the mean of the parents' heights. For girls, subtract 2.5 in or 6.5 cm from the mean of the parents' heights. This sex-adjusted mid-parental height represents the statistically most probable adult height for the child, based on parental contribution.
- Predicted Adult Height (assuming no intervention): Predicted based on current height, age, and a set of tables known as the Bayley-Pinneau tables, which use radiographic bone age to determine growth potential.

b) Somatropin Efficacy

i) Introduction

GH (somatropin) treatment is indicated for treatment of a variety of conditions that largely affect linear growth. FDA indications overlap to

some degree (see Table 1). All products except Zorbtive and Serostim are indicated to treat GHD, but only three are indicated for treatment of short stature associated with Turner Syndrome, and only one is indicated for treatment of Prader-Willi Syndrome. However, treatment endpoints are similar across all growth-related conditions, and treatment goals are achieved by physiologic replacement or supplementation of growth hormone.

Of prescriptions filled by the Air Force High Dollar Program in July 2007, 62% were for pediatric GHD, another 16% were for adult GHD, 8% were for panhypopituitarism, 6% were for Turner Syndrome, and the rest were split out across various miscellaneous indications. While these data are limited, usage of the growth hormones products by age across the MHS confirms that the great majority of use is for pediatric indications (usage peaks in the 5-14 year age group), with some use in adults (45 years and older).

ii) Somatropin Clinical Efficacy

All marketed somatropin products contain recombinant human GH that is bioequivalent and equally biopotent, and are therefore unlikely to differ in efficacy for the treatment of growth related disorders. There are no studies that compare two or more somatropin products for any indication.

- *Treatment of Childhood Growth Disorders* – Published evidence supports clinical efficacy of somatropin in achieving growth-related clinical endpoints in these conditions, including GHD, Turner Syndrome, Prader-Willi Syndrome, growth restriction related to chronic kidney disease, and small for gestational age. Clinical endpoints evaluated in published clinical trials comparing GH to untreated controls have included: total gains in height, increases in growth velocity, and final or near final adult height vs. mid-parental height or normal population means.
- *Treatment of Adult GHD* – Published evidence supports the clinical efficacy of somatropin treatment in achieving various clinical endpoints, including improvements in body composition (reduction of fat mass, increases in lean body mass); modest reductions in cardiovascular risk factors such as blood pressure, total and LDL cholesterol, and triglycerides; and reduction of C-reactive protein. Modest improvements in bone mineral density (4-10% via DEXA) have also been shown. The data do not support clinically and statistically meaningful improvements in adults without GHD.
- *HIV/AIDS related wasting / cachexia and sShort Bowel Syndrome (SBS) in adults* – GH has been demonstrated to be efficacious in these conditions. The use of somatropin in AIDS wasting results in increased lean body mass and improved muscular strength and endurance, compared to untreated controls. No mortality benefit has been demonstrated. Treatment of SBS with somatropin is based on

evidence that somatropin accelerates the process of bowel adaptation. This process involves morphologic changes of the remaining bowel allowing it to have greater absorption of nutrients and fluids and lessen the need for parenteral nutrition. Data are limited, but suggest that up to four weeks of GH treatment has been beneficial in reducing the need for parenteral nutrition in SBS patients.

- *Noonan Syndrome and Short Stature Homeobox gene (SHOX) deficiency* – The FDA recently approved somatropin for use in two additional pediatric growth disorders: Noonan Syndrome and SHOX deficiency. Both of these conditions are genetic disorders associated with severely restricted growth. Published clinical trials have demonstrated significant improvements in growth-related endpoints in both conditions, compared to untreated control patients.
- *Idiopathic Short Stature (ISS)* – ISS, or non-GHD short stature, refers to individuals who are at least 2.25 standard deviations shorter than the mean height for sex and age (the shortest 1.2% of the population). These individuals have no identified physiologic abnormality affecting growth and appear to be healthy otherwise. Growth velocity and final height gains are modest even with somatropin treatment; individuals usually remain shorter than average regardless of treatment. There are no data showing that the gains in height following GH treatment are associated with improvements in quality of life or psychosocial functioning. Treatment of ISS is not considered medically necessary and is therefore not a covered benefit under TRICARE.

iii) Mecasermin Clinical Efficacy

FDA approval of mecasermin was based on the results of five clinical trials, which are unpublished but summarized in product labeling. These trials enrolled a total of 71 children (mean age 7 years) with symptoms of primary IGFD (slow growth rates, low IGF-1 serum concentrations, and normal GH secretion) and extreme short stature (height almost 7 SD below normal). For years 1 through 6, pooled results showed a significant increase in height velocity in mecasermin-treated patients, compared to baseline. Although statistical interpretation was complicated by the uncontrolled, longitudinal nature of the data and the varying lengths of exposure to mecasermin treatment (range <1 to 11.5 years), children appeared to gain, on average, an additional one inch per year for each year on therapy, compared to pretreatment growth patterns.

Bone age, relative to chronological age, was assessed in 49 subjects, since a disproportional acceleration of bone age (specifically epiphyseal closure) could lessen the eventual height reached even if the drug was otherwise effective at accelerating growth. Radiographically-assessed bone age advanced only marginally above chronologic age (4.9 $\pm$ 3.4 years mean $\pm$ SD change in chronological age vs. A 5.3 + 33.4 years change in bone

age). Subjects felt to be close to adult height all exceeded the mean height of untreated subjects, suggesting a positive net effect.

iv) GSA Efficacy Conclusion

Somatropin appears to be efficacious for the treatment of a number of growth-related disorders, including GHD, Prader Willi Syndrome, Turner Syndrome, chronic renal insufficiency, children who are small for gestational age, SHOX deficiency, and Noonan Syndrome, as well as non-growth related disorders, including adult GHD, AIDS/HIV wasting, and SBS. There are no studies that compare any somatropin product to another for any given indication. Given that all of the products contain the same concentration (3 IU rhGH/mg) of bioidentical recombinant human growth hormone, they are unlikely to differ in efficacy for the treatment of growth-related or other disorders.

Mecasermin increased height in children with severe IGFD, especially in the first year of administration, but not enough to bring these children close to the normal range. It is unlikely to be as effective as GH treatment for children who can respond to GH.

3) *Safety and Tolerability*

a) Somatropin

Mortality in children with GHD is due almost entirely to other pituitary hormone deficiencies. These children have an increased relative risk of death in adulthood from cardiovascular causes resulting from altered body composition and dyslipidemia. Adverse effects of somatropin appear to be dose-related. Initial somatropin studies used higher doses associated with many adverse effects; lower dosages are currently used.

i) Serious Adverse Effects

- *Pseudotumor cerebri or benign intracranial hypertension* – This is more common in children than adults; the FDA has received at least 23 reports in children, 1 in an adult. In all cases, symptoms of intracranial hypertension (headaches) resolved after discontinuation of GH therapy. Only a few patients experienced recurrent headaches and papilledema upon resuming therapy.
- *Slipped capital femoral epiphysis* – This condition is attributed to GH therapy, but may be linked to the result of diathesis induced by GHD and intensified by rapid growth. Children on GH therapy complaining of hip or knee pain should be carefully examined for slipped capital femoral epiphysis.
- *Patients with acute catabolism* – Use of somatropin products is contraindicated in this patient population, including preoperative and post-operative patients, critically ill patients, and burn patients. In a phase III prospective, randomized, placebo-controlled trial in Europe conducted in critically ill patients in an intensive-care unit facility,

patients were given 5.3 mg or 8 mg per day (weight-dependant) of GH therapy for 21 days. A significantly higher mortality (41.7% vs. 18.2%) was seen in the GH-treated group compared to placebo.

- *Retinopathy* is a rare complication of GH treatment. Three case reports (1 adult; 2 children) reported development of retinopathy following GH treatment, although one trial involving 85 children showed no retinopathy after 6.4 ± 2.9 years. A baseline funduscopic evaluation is recommended before starting GH treatment.
- *Malignancies* – Concern has surfaced about the association of GH treatment with tumor recurrence or development of malignancies. This has not been reported in adult GHD patients. An increase in leukemia was reported in Japanese pediatric GHD patients, although this was not confirmed by subsequent studies. Studies in the United States did not confirm an increase in frequency and have shown some differences in incidence related to other risk factors, for example, patients who previously received radiation therapy. This question remains unanswered.

ii) More Common Adverse Effects reported with somatropin include injection site reactions, hypothyroidism, transient gynecomastia, headaches, agitation, fatigue, seizures, and nausea/vomiting. Fluid retention and edema of the extremities, as well as arthralgia, myalgia, carpal tunnel syndrome, and blood pressure increases, are reported primarily in adults. GH may also be associated with insulin resistance and glucose intolerance. Some adverse effects appear to be dose-related.

Reported rates of adverse effects do vary from product to product, although this is potentially due to a number of factors, including differences in dosing regimens for specific indications, patient populations studied, or methods of collecting adverse effects. All products contain the same molecular entity (somatropin).

- *Fluid retention, edema, arthralgia, myalgia, and carpal tunnel syndrome* – Adult starting doses for GH were initially higher than those currently recommended. These higher doses were associated with fluid retention in conjunction with edema of the extremities, resulting in arthralgias, myalgias, and carpal tunnel syndrome. These adverse effects are more frequent in adults but do occur occasionally in GH-treated pediatric patients. In a study of 115 adult patients with GHD given GH therapy for 6 months, 37.4% developed edema, 19.1% developed arthralgia, 15.7% myalgia, 7.8% paresthesias, and 1.7% carpal tunnel syndrome. Most adverse effects occurred at the beginning of treatment and resolved within 1 to 2 months with continued treatment. Fluid retention can also cause increases in blood pressure.
- *Effects on blood glucose* – High doses of GH have been associated with hypoglycemia followed by hyperglycemia, since GH induces

transient resistance to the actions of insulin. In patients with limited insulin reserve, glucose intolerance may result. Insulin resistance and type 2 diabetes were reported in a few patients in early large clinical trials. A placebo-controlled GH trial reported that a higher number of patients receiving GH had worsening glucose tolerance compared to those receiving placebo, with impaired glucose tolerance seen in 13% and diabetes in 4% of GH patients.

iii) Contraindications – Somatropin is contraindicated in patients with active neoplasms or intracranial lesions and treatment should be stopped if evidence of tumor growth develops. Treatment should not be initiated in patients with proliferative or preproliferative diabetic retinopathy; Prader Willi Syndrome patients who are severely obese or have severe respiratory impairment; acute critically ill patients; and patients with growth-related disorders whose epiphyses have closed. Somatropin products containing the preservative benzyl alcohol are not suitable for use in newborns.

iv) Drug-Drug Interactions – Limited published data suggest that somatropin treatment increases CYP450-mediated antipyrine clearance in man. Somatropin may therefore alter the clearance of compounds known to be metabolized by CYP450 liver enzymes (e.g., corticosteroids, sex steroids, anticonvulsants, or cyclosporine). Careful monitoring is advisable when somatropin is administered in combination with other drugs known to be metabolized by CYP450 liver enzymes. Formal drug interaction studies have not been conducted.

v) Tolerability – There is insufficient evidence to conclude that any one somatropin product is more tolerable or leads to better compliance than any other somatropin product. Any such differences are likely to be based on factors such as formulation / preservative differences and packaging.

Table 2: Somatropin Products – Other Consideration

Drugs	Preservative-free	Delivery Device			Storage		1-800 number
		Vial	Pen Device	Dose calculation to use pen	Ready to use	Room Temperature Storage	
Genotropin	yes		yes	Not required	Miniquick syringe only (single-dose)	Before initial use: Miniquick syringe	yes
Humatrope		yes	yes	Required			yes
Norditropin			yes	Not required	yes	After initial use: (21 days for Nordiflex 5 & 10 mg pens)	yes
Nutropin & Nutropin AQ		yes	yes	Required	yes		yes
Omnitrope	yes	yes		-			yes
Saizen		yes	yes, pen & needle-free pen	Required		Before initial use	yes
Serostim	yes	yes	yes, needle-free pen	Required		Before initial use	yes
Tev-Tropin		yes	*	-			yes
Zorbtive		yes		-			yes

*Approval of pen device anticipated

vi) *Other Considerations* – Since marketed somatropin products appear to be similar in efficacy and safety, the primary differences between products is based on educational materials; drug formulations / preservatives; delivery devices (pen or vial/syringe); and storage requirements (refrigeration vs. room temperature). Table 2 outlines differences between somatropin products with regard to many of these issues.

- *Educational material* – All manufacturers provide some type of educational material for their products, ranging from a hotline number for information and assistance to the patient or caregiver (provided by all manufacturers) to complete packages including a hotline number, website, nurse educator for initial instruction, and a safety registry website for physicians. The literature assessing the value of these educational programs is sparse. In MTFs, certain components of the educational programs are handled by MTF staff and manufacturer offerings such as nurse educators may be of little additional value.
- *Formulations* – The primary reason for the selection of preservatives is to prevent leaching of the drug into its glass or plastic container. The availability of a preservative-free product may be an advantage, although the need for such a product for use in infants should be rare. In addition, ready-to-use formulations that do not require reconstitution may increase accuracy of dosing.
- *Delivery Devices* – Availability of a product in a pen device allows for accuracy in dosing and may enhance compliance. Pens are available for these product lines: Genotropin, Humatrope, Norditropin, and Nutropin. Providers in general reported that patients prefer pens to vials; indeed, 67% of MHS utilization from June 2006 to July 2007 was for pens, followed by vials (26%) and disposable syringes (7%).

  Some pen devices conceal the needle from view, an advantage in children who fear needles. The Serono products, Saizen and Serostim, are the only products with a needle-free pen device. An additional consideration is the requirement for dose calculations on the part of the caregiver/patient; some pens require users to convert the milligram dose prescribed to the units dosed on the pen. Products requiring conversions are the Nutropin product line, Saizen, and Serostim.
- *Drug Wastage* – Packaging for the two somatropin products that lack a GHD indication (Serostim and Zorbtive) is designed for dosage regimens used in AIDS/HIV wasting and SBS, not for use in GHD. Drug wastage would be inevitable if these products were used for GHD. In addition, educational materials available for these products do not address GHD.

b) Mecasermin

i) Serious Adverse Effects

- *Hypoglycemia* – Mecasermin can cause hypoglycemia due to its insulin-like effects. Hypoglycemia was reported in 30 of 71 patients in clinical trials (42%) at least once during their course of therapy. Most cases of hypoglycemia were mild or moderate in severity. Five patients had severe hypoglycemia that required assistance and treatment on one or more occasion, while four experienced hypoglycemic seizures/loss of consciousness on one or more occasion. Of the 30 patients reporting hypoglycemia, 14 (47%) had a history of hypoglycemia before treatment. The incidence of hypoglycemia was highest in the first month of therapy, and episodes were more frequent in younger children. Symptomatic hypoglycemia was usually avoided when a meal or snack was consumed either shortly (i.e., 20 minutes) before or after the administration of mecasermin.
- *Lymphoid tissue hypertrophy* – Hypertrophy of lymphoid tissues (e.g. Tonsillar) can result in snoring, sleep apnea, and chronic middle-ear effusions. Tonsillar hypertrophy was noted in 11 (15%) subjects in the first 1 to 2 years of therapy with lesser tonsillar growth in succeeding years. Tonsillectomy or tonsillectomy/adenoidectomy was performed in 7 subjects; 3 of these had obstructive sleep apnea, which resolved after the surgery in all three cases.
- *Intracranial hypertension* – Intercranial hypertension with papilledema, visual changes, headache, nausea and/or vomiting have been reported with mecasermin (as with therapeutic GH administration). Intracranial hypertension occurred in three subjects, and in two subjects, resolved without interruption of mecasermin treatment. Mecasermin therapy was discontinued in the third subject and resumed later at a lower dose without recurrence.
- *Scoliosis* due to slipped capital femoral epiphysis can occur with rapid growth.

ii) Common Adverse Effects reported in the pooled mecasermin trials were hypoglycemia (42% of patients), lipohypertrophy, and tonsillar hypertrophy (15%). Other adverse effects occurring in at least 5% of patients include bruising, otitis media, headache, dizziness, convulsions, vomiting, hypoacusis, fluid in the middle ear, ear pain, abnormal tympanometry, arthralgia, pain in extremity, and thymus hypertrophy. Adverse effects were generally mild to moderate and no patients withdrew from the pooled trials as a result.

Also reported during clinical trials were: mild elevations in serum AST, alanine aminotransferase (ALT), and lactate dehydrogenase not leading to treatment discontinuation; increases in cholesterol and triglycerides to above the upper limit of normal; increases in renal and/or splenic length

reaching or surpassing the 95th percentile in some patients but not associated with impairments in renal function (as defined by serum creatinine and calculated creatinine clearance); echocardiographic evidence of cardiomegaly/valvulopathy without associated clinical symptoms ; and development of anti-IGF-1 antibodies with no apparent clinical consequence (e.g., allergic reactions or attenuation of growth).

iii) Contraindications – Mecasermin is contraindicated in patients whose epiphyses are already closed and those with active or suspected neoplasia. Mecasermin is not suitable for use in neonates due to its benzyl alcohol preservative.

iv) Monitoring – Preprandial glucose monitoring should be considered at treatment initiation, until a well tolerated dose is established, or if frequent or severe symptoms of hypoglycemia occur. Funduscopic exams are recommended at the start of therapy and periodically thereafter. Patients should also be monitored for *t*hickening of soft tissues of the face and symptoms suggesting the occurrence of scoliosis due to a slipped capital femoral epiphysis.

v) Special Populations – Safety and effectiveness has not been established in children less than 2 years of age or in adults.

c) Safety/Tolerability Conclusion

i) Growth Hormone (Somatropin)

Serious adverse events of GH include benign intracranial hypertension, slipped capital femoral epiphyses, and retinopathy. Whether or not GH treatment has tumorigenic effects remains debatable, due to possible associations with underlying disease states. The most common adverse events are edema, arthralgias, injections site reactions, diabetogenic effects, and hypothyroidism. Consistent lab monitoring is necessary to decrease the potential for adverse effects from possible excessive dosing or exacerbation of other disease states; required monitoring does not differ among marketed products. GH is not recommended in critically ill patients.

Although all products contain the same molecular entity, reported rates of adverse events vary from product to product, possibly due to different dosing schemes for specific indications or differences between study populations. There is limited evidence concerning differences between products attributable to excipients. Preservatives are primarily used as a way to prevent the drug leaching into the plastic or glass container. Products containing the preservative benzyl alcohol are not suitable for use in newborns; preservative-free products are available.

Since marketed somatropin products appear to be similar in efficacy and safety, the primary differences between products is based on educational materials; drug formulations / preservatives; delivery devices (pen or

vial/syringe); and storage requirements (refrigeration vs. room temperature).

The biggest difference is in available delivery devices (e.g., a pen device, vial/syringe, needle-less system). A pen device is advantageous for ease of use and may increase accuracy in dosing. A pen device that does not require the caregiver or patient to convert from milligrams to "units" or "clicks" is more convenient and less likely to cause errors than one that requires conversion. Only one manufacturer, Serono, offers a needle-free device (for Saizen and Serostim).

Most of the products require refrigeration before and after initial use; products with room temperature storage may be advantageous in terms of limiting waste of the product and facilitating use while traveling. All products have a hotline number for patients and caregivers; other materials vary.

ii) Mecasermin

Mecasermin can cause disruptions in blood glucose and may require blood glucose monitoring. Lymphoid tissue hypertrophy, intracranial hypertension: and scoliosis due to slipped capital femoral epiphysis related to rapid growth can also occur.

4) *Overall Clinical Effectiveness Conclusion* – The P&T Committee concluded that:

a) Somatropin products appear to be safe and efficacious for the treatment of various growth-related conditions and for a few specialized non-growth related conditions.

b) There are no studies comparing any somatropin product to another for any given indication. Given that all of the products contain the same concentration (3 IU rhGH/mg) of bioidentical recombinant human growth hormone, they are unlikely to differ in efficacy for the treatment of growth-related or other disorders.

c) There are potential differences between somatropin products with respect to delivery devices, formulations, and stability/storage requirements. Differences that may favor particular products include availability of a pen device (preferably along with a vial/syringe product); the ability to use the pen device without having to do dose conversions, and the ability to store products at room temperature before or after initial use.

d) Mecasermin is safe and efficacious for severe IGF-1 deficiency, a much rarer condition than GHD. It is the only product available for the treatment of this condition.

e) Based on clinical issues alone, there are no compelling reasons to classify any of the GSA agents as non-formulary under the UF.

COMMITTEE ACTION: The P&T Committee voted (15 for, 0 opposed, 0 abstained, 2 absent) to accept the clinical effectiveness conclusions above.

B. GSAs – Relative Cost Effectiveness

In considering the relative cost effectiveness of pharmaceutical agents in this class, the P&T Committee evaluated the costs of the agents in relation to the efficacy, safety, tolerability, and clinical outcomes of the other agents in the class. Information considered by the P&T Committee included but was not limited to sources of information listed in 32 CFR 199.21(e)(2).

The GSAs are divided into the IGF-1 and somatropin subclasses. The sole IGF-1 agent is mecasermin. It is indicated for the treatment of IGF-1 deficiency and therefore occupies a unique place in therapy within the GSAs. Among the somatropin products, two (Serostim and Zorbtive) are primarily used in disorders most commonly seen in adult patients (HIV wasting and short bowel syndrome). These two somatropin products are therefore available in dosage forms/ concentrations that would make delivery of a pediatric dose difficult. For these reasons, mecasermin, Serostim, and Zorbtive were excluded from the CMA and BIA. However, they were compared to the other GSAs on a cost per milligram basis.

The relative clinical effectiveness evaluation concluded that there was insufficient evidence to suggest that the remaining somatropin products within the GSA class differed in regards to efficacy, safety, tolerability, or clinical outcomes data in the treatment of GHD. As a result, CMA was performed to compare the relative cost effectiveness of these somatropin products.

Results from the somatropin CMA revealed: 1) Tev-Tropin was the most cost effective somatropin product. However, Tev-Tropin does not offer some of the features (pen dosage forms, storage at room temperature, and ease of use) that some of the more costly products offer; 2) two product lines, Norditropin and Nutropin, are the most cost effective agents that offer physician- and patient-preferred features.

The BIA evaluated the potential impact of various scenarios with one or more somatropin products designated as formulary on the UF. The BIA included a single agent in front of a step-edit (automated PA) as well as two or more (up to all) somatropin products on the UF.

Cost Effectiveness Conclusion – The P&T Committee concluded that:

1) Mecasermin and two somatropin products (Zorbtive and Serostim) have a specific niche in therapy and are offer sufficient value on a cost/mg basis relative to the other agents within the therapeutic class.
2) Tev-Tropin was the most cost effective somatropin agent based on cost-minimization analysis. However, the product offers fewer features than most other growth stimulating agent product lines.
3) Two somatropin product lines, Norditropin and Nutropin, offered more features (pen dosage forms, storage at room temperature, and ease of use) at a middle range of cost.
4) The BIA results showed that the most cost effective formulary strategy for the somatropin products was the combination of the Tev-tropin and the Norditropin and Nutropin product lines.

COMMITTEE ACTION: The P&T Committee voted (15 for, 0 opposed, 0 abstention, and 2 absent) to accept the GSA relative cost effectiveness analysis as presented by the PEC.

C. GSAs – UF Recommendations

COMMITTEE ACTION – Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of the GSA agents, and other relevant factors, the P&T Committee, based upon its collective professional judgment, voted (13 for, 0 opposed, 1 abstained, 3 absent) to recommend that Tev-Tropin, Nutropin, Nutropin AQ, Norditropin, Nortropin Nordiflex, Serostim, Zorbtive, and mecasermin be maintained as formulary on the UF and that the Genotropin, Humatrope, Saizen and Omnitrope brands of somatropin be classified as non-formulary under the UF.

D. GSAs – MN Criteria

Based on the clinical evaluation and the conditions for establishing MN for a non-formulary medication provided for in the UF rule, the P&T Committee recommended the following general MN criteria for the somatropin products Genotropin, Humatrope, Saizen and Omnitrope:

1) Use of formulary alternatives is contraindicated.
2) The patient has experienced or is likely to experience significant adverse effects from formulary alternatives.

The P&T Committee noted that since the somatropin products all contain the same active ingredient, the most likely scenario under which criterion #2 would apply would be issues specific to specific formulations / preservatives (e.g., injection site reactions).

COMMITTEE ACTION: The P&T Committee voted (13 for, 0 opposed, 1 abstained, 3 absent) to approve the MN criteria outlined above.

E. GSAs – UF Implementation Period

The P&T Committee recommended an effective date of the first Wednesday following a 60-day implementation period at the TMOP and TRRx, and at the MTFs no later than a 60-day implementation period. The implementation period will begin immediately following approval by the Director, TMA.

MTFs will not be allowed to have the somatropin products Genotropin, Humatrope, Saizen and Omnitrope on their local formularies. MTFs will be able to fill non-formulary requests for these agents only if both of the following conditions are met: 1) the prescription must be written by a MTF provider, and 2) MN is established. MTFs may (but are not required to) fill a prescription for a non-formulary Somatropin agent written by a non-MTF provider to whom the patient was referred, as long as MN has been established.

COMMITTEE ACTION: The P&T Committee recommended (13 for, 0 opposed, 1 abstained, 3 absent) an effective date of the first Wednesday following a 60-day implementation period at the TMOP and TRRx, and at the MTFs no later than a 60-

day implementation period. The implementation period will begin immediately following the approval by the Director, TMA.

F. GSAs – PA Criteria

Currently, PA criteria apply to both GH (somatropin products) and mecasermin. The P&T Committee voted (13 for, 0 opposed, 1 abstained, 3 absent) that the following PA criteria should apply to GH and mecasermin. Changes from previous GH (somatropin) criteria are the addition of Noonan's Syndrome and SHOX deficiency as covered uses; no changes were recommended to mecasermin criteria.

1) *Growth Hormone (Somatropin)* – Coverage would be approved for the treatment of any of the following:
   a) GHD in children and adults as a result of pituitary disease, hypothalamic disease, surgery or radiation therapy
   b) Chronic renal insufficiency before renal transplantation with associated short stature
   c) Other known renal indications: autorecessive polycystic kidney disease, cystinosis and hypophosphatemic rickets in the pediatric population
   d) Short stature in patients with Turner Syndrome or Prader-Willi Syndrome
   e) Infants born small for gestational age that have not reached age appropriate height by 24 months of age
   f) Human immunodeficiency virus-associated wasting in adults
   g) Noonan Syndrome
   h) SHOX deficiency
2) *Mecasermin* – Coverage would be approved for the treatment of:
   a) Patients with severe primary IGFD defined by the following:
      i) Height standard deviation score $\leq$ -3
      ii) Basal IGF-1 standard deviation score $\leq$ -3
      iii) Normal or elevated GH levels

      OR
   b) Patients with GH gene deletion who have developed neutralizing antibodies to GH

   In addition, patients must meet the following criteria:

   - Are receiving ongoing care under the guidance of a health care provider skilled in the diagnosis and management of patients with growth disorders (e.g., pediatric endocrinologist)
   - Thyroid and nutritional deficiencies have been corrected before initiating mecasermin treatment
   - Have been educated on monitoring and management of hypoglycemia

Coverage is NOT provided for:

- Patients with closed epiphyses (bone growth plates)
- Patients with active or suspected neoplasia (therapy should be discontinued if evidence of neoplasia develops)
- Patients with other causes of growth failure (secondary forms of IGF-1 deficiency, such as GHD, malnutrition, hypothyroidism, or chronic treatment with pharmacologic doses of anti-inflammatory steroid

COMMITTEE ACTION: The P&T Committee voted (14 for, 0 opposed, 1 abstained, 2 absent) to recommend the PA criteria outlined above.

G. GSAs – Extended Core Formulary (ECF) Review and Recommendations

The P&T Committee considered the ECF status of the GSA agents. Based on the results of the clinical and economic evaluations presented, the P&T Committee voted (13 for, 0 opposed, 1 abstained, and 3 absent) to recommend that Norditropin / Norditropin Nordiflex be added to the ECF.

9. QUANTITY LIMITS

A. Rizatriptan (Maxalt) – The current QL for rizatriptan tablets and orally disintegrating tablets (Maxalt, Maxalt MLT) is 18 tablets per 30 days, or 36 tablets per 90 days. This QL was increased from 12 to 18 tablets per 30 days in May 2006 to accommodate a change in packaging (from 6 tablets per package to 9 tablets per package). Packaging for rizatriptan recently changed again, from 9 tablets per package to 12 tablets per package. QLs for triptans are based on the lack of safety evidence for treating more than 3-4 headaches per month with triptans, dosing recommendations, and package size.

***COMMITTEE ACTION*:** The Committee voted (14 for, 0 opposed, 1 abstained, 2 absent) to recommend changing the QL for rizatriptan tablets and orally disintegrating tablets to 12 tablets per 30 days, or 36 tablets per 90 days.

10. BCF STATUS OF ROSIGLITAZONE

Rosiglitazone (Avandia) – The PEC updated the P&T Committee on the two recent alerts issued by the FDA regarding rosiglitazone.

1) *FDA Alert #1: 8/14/2007:* Important revisions to the full prescribing information (labeling) highlighting increased risks of congestive heart failure associated with rosiglitazone. The updated information includes a new BOXED WARNING, and additional updated WARNINGS, PRECAUTIONS and CONTRAINDICATIONS to emphasize that rosiglitazone may cause or exacerbate heart failure, particularly in certain patient populations. *Source*: www.fda.gov/cder/drug/InfoSheets/HCP/rosiglitazone200707HCP.htm

2) FDA Alert #2: 5/21/2007**:** Ongoing FDA review of clinical data to assess a potential increased risk of ischemic cardiovascular events in patients taking rosiglitazone. FDA is aware of a potential safety issue related to rosiglitazone maleate. Safety data from a pooled analysis of controlled clinical trials have shown a significant increase in the risk of heart attack and heart-related deaths in patients taking rosiglitazone.

However, other published and unpublished data from long-term clinical trials of rosiglitazone provide contradictory evidence about the risk of ischemic cardiovascular events in patients taking rosiglitazone. FDA's review of all available data is ongoing. FDA has not confirmed the clinical significance of the reported increased risk of ischemic cardiovascular events in the context of other studies. Myocardial ischemic events are currently described in the WARNINGS section of the rosiglitazone label. FDA does not know whether the other approved medication in the same pharmacologic class or other oral drugs for treating type 2 diabetes have less, the same, or greater risks. Switching diabetic patients to other therapies also confers its own risks. For those reasons, FDA is providing this emerging information to prescribers so that they and their patients can make individualized treatment decisions. *Source:* www.fda.gov/cder/drug/InfoSheets/HCP/rosiglitazone200707HCP.htm

The P&T Committee discussed the advantages and disadvantages of removing rosiglitazone from the BCF. Ultimately, the P&T Committee determined that there was insufficient clinical evidence to justify removal of rosiglitazone from the BCF at this time. The PEC will update the P&T Committee as more information becomes available.

***COMMITTEE ACTION*:** The Committee voted (7 for, 6 opposed, 1 abstained, 3 absent) to not remove rosiglitazone from the BCF at this time.

11. BCF / ECF REVIEW

The P&T Committee agreed with the PEC's plan to systematically review drug classes represented on the BCF over the next few meetings with the goals of: 1) removing obsolete medications, 2) defining BCF listings more specifically, 3) reframing or revising BCF listings to be compatible with drug classes as defined or outlined by the P&T Committee, and 4) assessing the need for future review. The P&T Committee agreed that BCF/ECF listings will in the future be framed with greater specificity as drug classes are reviewed or reviewed.

The P&T Committee made initial recommendations for clarifying BCF listings in three drug classes or potential drug classes, including atypical antipsychotics (quetiapine and risperidone), osteoporosis agents (alendronate/vitamin D), and cough-cold medications (guaifenesin/pseudoephedrine). Details are outlined in Appendix C.

COMMITTEE ACTION: The P&T Committee recommended the following changes to BCF / ECF listings (see Appendix C for rationale):

Table 3: Recommended BCF / ECF Changes

Drug class or potential drug class	Current BCF / ECF listing	Recommendation	Vote			
			For	Opposed	Abstained	Absent
Atypical antipsychotics	BCF – "Quetiapine"	Clarify BCF listing to: "quetiapine tablets, immediate and extended release"	14	0	1	2
	BCF – "Risperidone oral; does not include orally disintegrating tablets (Risperdal Redi-tabs)"	Clarify BCF listing to: "Risperidone tablets and solution, does not include orally disintegrating tablets"	14	0	1	2
Osteoporosis agents	BCF – "Alendronate 70 mg / vitamin D 2800 IU (Fosamax Plus D)"	Clarify BCF listing to specify new product with higher strength of vitamin D – "Alendronate 70 mg/vitamin D 5600 IU tablets"	14	0	1	2
Cough-cold medications	BCF – "Guaifenesin 600 / PSE 120 mg ER oral"	Remove from BCF	14	0	1	2

12. CLASS OVERVIEWS

Class overviews for the osteoporosis agents were presented to the P&T Committee. The P&T Committee provided expert opinion regarding those clinical outcomes considered most important for the PEC to use in completing the clinical effectiveness review and developing the appropriate cost effectiveness models. The clinical and economic analyses of these classes will be completed during the February 2008 meeting; no action is necessary.

13. ADJOURNMENT

The second day of the meeting adjourned at 1700 hours on 15 August 2007. The next meeting will be 14-15 November 2007.

Captain, Medical Corps, U.S. Navy
Chairperson

Appendix A – Implementation Status of UF Class Review Recommendations / Decisions

Meeting	Drug Class	Non-Formulary Medications	BCF/ ECF Class	BCF/ECF Medications	Decision Date (DoD P&T minutes signed, effective date for BCF/ECF medications)	Effective Date for Non-Formulary Medications (Implementation period)
Aug 07	Newer Antihistamines	▪ desloratadine (Clarinex) ▪ desloratadine/pseudoephedrine (Clarinex D)	BCF	▪ MTFs required to carry at least one single ingredient agent from the newer antihistamine class (loratadine, cetirizine, or fexofenadine) on their local formulary, including at least one dosage form suitable for pediatric use	Pending approval	Pending approval
Aug 07	Leukotriene Modifiers	▪ Zileuton (Zyflo)	BCF	▪ montelukast (Singulair)	Pending approval	Pending approval
Aug 07	Growth Stimulating Agents	▪ somatropin (Genotropin, Genotropin Miniquick) ▪ somatropin (Humatrope) ▪ somatropin (Omnitrope) ▪ somatropin (Saizen)	ECF	▪ somatropin (Norditropin)	Pending approval	Pending approval
Nov 05 (updated for new drug Aug 07)	Nasal Corticosteroids	▪ beclomethasone dipropionate (Beconase AQ, Vancenase AQ) ▪ budesonide (Rhinocort Aqua) ▪ triamcinolone (Nasacort AQ)	BCF	▪ fluticasone propionate (Flonase)	19 Jan 06	19 Apr 06 (90 days)
		Recommended Aug 07 ▪ fluticasone furoate (Veramyst)			Pending approval	Pending approval
May 07 re-review (Feb 05 original)	PPIs	▪ lansoprazole (Prevacid) ▪ omeprazole/sodium bicarbonate (Zegerid) ▪ pantoprazole (Protonix) ▪ rabeprazole (Aciphex)	BCF	▪ generic omeprazole 10 mg and 20 mg (excludes Prilosec 40 mg) ▪ esomeprazole (Nexium)	24 July 07	24 Oct 07 (90 days)
May 07	Antilipidemic Agents II	▪ fenofibrate nanocrystallized (Tricor) ▪ fenofibrate micronized (Antara) ▪ omega-3 fatty acids (Omacor) ▪ colesevelam (Welchol)	BCF	▪ gemfibrozil ▪ fenofibrate IDD-P (Triglide)	24 July 07	21 Nov 07 (120 days)
May 07 re-review (Feb 05 original)	ARBs	▪ eprosartan (Teveten) ▪ eprosartan HCTZ (Teveten HCT) ▪ irbesartan (Avapro) ▪ irbesartan HCTZ (Avalide) ▪ olmesartan (Benicar) ▪ olmesartan HCTZ (Benicar HCT) ▪ valsartan (Diovan) ▪ valsartan HCTZ (Diovan HCT)	BCF	▪ telmisartan (Micardis) ▪ telmisartan HCTZ (Micardis HCT)	24 July 07	21 Nov 07 (120 days)

Meeting	Drug Class	Non-Formulary Medications	BCF/ ECF Class	BCF/ECF Medications	Decision Date (DoD P&T minutes signed, effective date for BCF/ECF medications)	Effective Date for Non-Formulary Medications (Implementation period)
May 07	5-Alpha Reductase Inhibitors	▪ dutasteride (Avodart)	BCF	▪ finasteride	24 July 07	24 Oct 07 (90 days)
Feb 07	Newer Sedative Hypnotics	▪ zolpidem ER (Ambien CR) ▪ zaleplon (Sonata) ▪ ramelteon (Rozerem)	BCF	▪ zolpidem IR (Ambien)	02 May 07	01 Aug 07 (90 days)
Feb 07	Narcotic Analgesics	▪ tramadol ER (Ultram ER)	BCF	▪ morphine sulfate IR 15 mg, 30 mg ▪ morphine sulfate 12-hour ER (MS Contin or equivalent) 15, 30, 60 mg ▪ oxycodone/APAP 5/325 mg ▪ hydrocodone/APAP 5/500 mg ▪ codeine/APAP 30/300 mg ▪ codeine/APAP elixir 12/120 mg/5 mL ▪ tramadol IR	02 May 07	01 Aug 07 (90 days)
Feb 07	Ophthalmic Glaucoma Agents	▪ travoprost (Travatan, Travatan Z) ▪ timolol maleate for once daily dosing (Istalol) ▪ timolol hemihydrate (Betimol) ▪ brinzolamide (Azopt)	BCF	▪ latanoprost (Xalatan) ▪ brimonidine (Alphagan P); excludes 0.1% ▪ timolol maleate ▪ timolol maleate gel-forming solution ▪ pilocarpine	02 May 07	01 Aug 07 (90 days)
Nov 06	Older Sedative Hypnotics	-	BCF	▪ temazepam 15 and 30 mg	17 Jan 07	NA
Nov 06	ADHD Agents	▪ dexmethylphenidate IR (Focalin) ▪ dexmethylphenidate SODAS (Focalin XR) ▪ methylphenidate transdermal system (Daytrana)	BCF	▪ methylphenidate OROS (Concerta) ▪ mixed amphetamine salts ER (Adderall XR) ▪ methylphenidate IR (Ritalin)	17 Jan 07	18 Apr 07 (90 days)
Aug 06	TZDs	-	BCF	▪ rosiglitazone (Avandia) ▪ rosiglitazone / metformin (Avandamet)	23 Oct 06	NA
Aug 06	H2 Antagonists / GI protectants	-	BCF	▪ ranitidine (Zantac) – excludes gelcaps and effervescent tablets	23 Oct 06	NA
Aug 06	Antilipidemic Agents I	▪ rosuvastatin (Crestor) ▪ atorvastatin / amlodipine (Caduet)	BCF	▪ simvastatin (Zocor) ▪ pravastatin ▪ simvastatin / ezetimibe (Vytorin) ▪ niacin extended release (Niaspan)	23 Oct 06	1 Feb 07 (90 days)

Meeting	Drug Class	Non-Formulary Medications	BCF/ ECF Class	BCF/ECF Medications	Decision Date (DoD P&T minutes signed, effective date for BCF/ECF medications)	Effective Date for Non-Formulary Medications (Implementation period)
May 06 (updated for new drugs Nov 06)	Contraceptives	▪ EE 30 mcg / levonorgestrel 0.15 mg in special packaging for extended use (Seasonale) ▪ EE 25 mcg / norethindrone 0.4 mg (Ovcon 35) ▪ EE 50 mcg / norethindrone 1 mg (Ovcon 50) ▪ EE 20/30/35 mcg / norethindrone 1 mg (Estrostep Fe)	BCF	▪ EE 20 mcg / 3 mg rospirenone (Yaz) ▪ EE 20 mcg / 0.1 mg levonorgestrel (Alesse, Levlite, or equivalent) ▪ EE 30 mcg / 3 mg drospirenone (Yasmin) ▪ EE 30 mcg / 0.15 mg levonorgestrel (Nordette or equivalent / excludes Seasonale) ▪ EE 35 mcg / 1 mg norethindrone (Ortho-Novum 1/35 or equivalent) ▪ EE 35 mcg / 0.25 mg norgestimate (Ortho-Cyclen or equivalent) ▪ EE 25 mcg / 0.18/0.215/0.25 mg norgestimate (Ortho Tri-Cyclen Lo) ▪ EE 35 mcg / 0.18/0.215/0.25 mg norgestimate (Ortho Tri-Cyclen or equivalent) ▪ 0.35 mg norethindrone (Nor-QD, Ortho Micronor, or equivalent)	26 Jul 06	24 Jan 07 (180 days)
		Recommended Nov 06 ▪ EE 30/10 mcg / 0.15 mg levonorgestrel in special packaging for extended use (Seasonique) ▪ EE 20 mcg / 1 mg norethindrone (Loestrin 24 Fe)			17 Jan 07	18 Mar 07 (60 days)
May 06	Antiemetics	▪ dolasetron (Anzemet)	BCF	▪ promethazine (oral and rectal)	26 Jul 06	27 Sep 06 (60 days)
Feb 06	OABs	▪ tolterodine IR (Detrol) ▪ oxybutynin patch (Oxytrol) ▪ trospium (Sanctura)	BCF	▪ oxybutynin IR (Ditropan tabs/soln) ▪ tolterodine SR (Detrol LA)	26 Apr 06	26 Jul 06 (90 days)
Feb 06	Misc Antihypertensive Agents	▪ felodipine/enalapril (Lexxel) ▪ verapamil/trandolapril (Tarka)	BCF	▪ amlodipine/benazepril (Lotrel) ▪ hydralazine ▪ clonidine tablets	26 Apr 06	26 Jul 06 (90 days)
Feb 06	GABA-analogs	▪ pregabalin (Lyrica)	BCF	▪ gabapentin	26 Apr 06	28 Jun 06 (60 days)
Nov 05	Alzheimer's Drugs	▪ tacrine (Cognex)	ECF	▪ donepezil (Aricept)	19 Jan 06	19 Apr 06 (90 days)
Nov 05 (updated Aug 07)	Nasal Corticosteroids	▪ beclomethasone dipropionate (Beconase AQ, Vancenase AQ) ▪ budesonide (Rhinocort Aqua) ▪ triamcinolone (Nasacort AQ)	BCF	▪ fluticasone (Flonase)	19 Jan 06	19 Apr 06 (90 days)

Meeting	Drug Class	Non-Formulary Medications	BCF/ ECF Class	BCF/ECF Medications	Decision Date (DoD P&T minutes signed, effective date for BCF/ECF medications)	Effective Date for Non-Formulary Medications (Implementation period)
Nov 05	Macrolide/ Ketolide Antibiotics	▪ azithromycin 2 gm (Zmax) ▪ telithromycin (Ketek)	BCF	▪ azithromycin (Z-Pak) ▪ erythromycin salts and bases	19 Jan 06	22 Mar 06 (60 days)
Nov 05	Antidepressants I	▪ paroxetine HCl CR (Paxil) ▪ fluoxetine 90 mg for weekly administration (Prozac Weekly) ▪ fluoxetine in special packaging for PMDD (Sarafem) ▪ escitalopram (Lexapro) ▪ duloxetine (Cymbalta) ▪ bupropion extended release (Wellbutrin XL)	BCF	▪ citalopram ▪ fluoxetine (excluding weekly regimen and special packaging for PMDD) ▪ sertraline (Zoloft) ▪ trazodone ▪ bupropion sustained release	19 Jan 06	19 Jul 06 (180 days)
Aug 05	Alpha Blockers for BPH	▪ tamsulosin (Flomax)	BCF	▪ terazosin ▪ alfuzosin (Uroxatral)	13 Oct 05	15 Feb 06 (120 days)
Aug 05	CCBs	▪ amlodipine (Norvasc) ▪ isradipine IR (Dynacirc) ▪ isradipine ER (Dynacirc CR) ▪ nicardipine IR (Cardene, generics) ▪ nicardipine SR (Cardene SR) ▪ verapamil ER (Verelan) ▪ verapamil ER for bedtime dosing (Verelan PM, Covera HS) ▪ diltiazem ER for bedtime dosing (Cardizem LA)	BCF	▪ nifedipine ER (Adalat CC) ▪ verapamil SR ▪ diltiazem ER (Tiazac)	13 Oct 05	15 Mar 06 (150 days)
Aug 05	ACE Inhibitors & ACE Inhibitor / HCTZ Combinations	▪ moexipril (Univasc), ▪ moexipril / HCTZ (Uniretic) ▪ perindopril (Aceon) ▪ quinapril (Accupril) ▪ quinapril / HCTZ (Accuretic) ▪ ramipril (Altace)	BCF	▪ captopril ▪ lisinopril ▪ lisinopril / HCTZ	13 Oct 05	15 Feb 06 (120 days)
May 05	PDE-5 Inhibitors	▪ sildenafil (Viagra) ▪ tadalafil (Cialis)	ECF	▪ vardenafil (Levitra)	14 Jul 05	12 Oct 05 (90 days)
May 05 (updated for new drugs Nov 06)	Topical Antifungals*	▪ econazole ▪ ciclopirox ▪ oxiconazole (Oxistat) ▪ sertaconazole (Ertaczo) ▪ sulconazole (Exelderm)	BCF	▪ nystatin ▪ clotrimazole	14 Jul 05	17 Aug 05 (30 days)
		Recommended Nov 06: ▪ 0.25% miconazole / 15% zinc oxide / 81.35% white petrolatum ointment (Vusion)			17 Jan 07	18 Mar 07 (60 days)

Meeting	Drug Class	Non-Formulary Medications	BCF/ ECF Class	BCF/ECF Medications	**Decision Date** (DoD P&T minutes signed, effective date for BCF/ECF medications)	**Effective Date for Non-Formulary Medications** (Implementation period)
May 05	MS-DMDs	-	ECF	▪ interferon beta-1a intramuscular injection (Avonex)	14 Jul 05	-
Feb 05	ARBs – see May 07 for re-review	▪ eprosartan (Teveten) ▪ eprosartan/HCTZ (Teveten HCT)	BCF	▪ telmisartan (Micardis) ▪ telmisartan/HCTZ (Micardis HCT)	18 Apr 05	17 Jul 05 (90 days)
Feb 05	PPIs – see May 07 for re-review	▪ esomeprazole (Nexium)	BCF	▪ omeprazole ▪ rabeprazole (Aciphex)	18 Apr 05	17 Jul 05 (90 days)

BCF = Basic Core Formulary; ECF = Extended Core Formulary; ESI = Express-Scripts, Inc; MN = Medical Necessity; TMOP = TRICARE Mail Order Pharmacy; TRRx = TRICARE Retail Pharmacy program; UF = Uniform Formulary

ER = extended release; IR = immediate release; SR = sustained release; IDD-P = insoluble drug delivery-microParticle

ADHD = Attention Deficit Hyperactivity Disorder; ARBs = Angiotensin Receptor Blockers; ACE Inhibitors = Angiotensin Converting Enzyme Inhibitors; BPH = Benign Prostatic Hyperplasia; CCBs = Calcium Channel Blockers; EE = ethinyl estradiol; GI = gastrointestinal; GABA = gamma-aminobutyric acid; H2 = Histamine-2 receptor; HCTZ = hydrochlorothiazide; MS-DMDs = Multiple Sclerosis Disease-Modifying Drugs; OABs = Overactive Bladder Medications; PDE-5 Inhibitors = Phosphodiesterase-5 inhibitors; PPIs = Proton Pump Inhibitors; TZDs = thiazolidinediones

*The topical antifungal drug class excludes vaginal products and products for onychomycosis (e.g., ciclopirox topical solution [Penlac])

Appendix B – Newly Approved Drugs. August 2007 DoD P&T Committee Meeting

Medication (Brand name; manufacturer) mechanism of action	**FDA Approval Date & FDA-Approved Indications**	**Committee Recommendation**
Budesonide / formoterol inhaler (Symbicort, Astra Zeneca) corticosteroid with long-acting beta agonist	Jul 06 (launched Jul 07) ▪ Long term maintenance treatment of asthma in patients 12 years of age and older.	No UF recommendation at this meeting. Consideration of UF status deferred until inhalational asthma drugs are reviewed; UF review anticipated within the next 12 months. Quantity limits recommended: ▪ TMOP o #3 inhalers per 90 days ▪ Retail Network o #1 inhaler per 30 days
Rotigotine topical patch (Neupro; Schwarz Biosciences) non-ergoline D3/D2/D1 dopamine agonist	May 07 (launched Jul 07) ▪ Treatment of signs and symptoms of early stage idiopathic Parkinson's disease	No UF recommendation at this meeting. Consideration of UF status deferred until Parkinson's drugs are reviewed; UF review not anticipated in the next 12 months.
Estradiol 0.1% gel (Divigel; Upsher-Smith) estrogen for hormone replacement	Jun 07 (launched Aug 07) ▪ Treatment of moderate to severe hot flashes associated with menopause.	No UF recommendation at this meeting. Consideration of UF status deferred until hormone replacement therapies are reviewed; UF review not anticipated in the next 12 months.
Estradiol 0.06% gel (Elestrin; Bradley Pharmaceuticals) estrogen for hormone replacement	Dec 06 (launched Jun 07) Treatment of moderate to severe vasomotor symptoms associated with menopause.	No UF recommendation at this meeting. Consideration of UF status deferred until hormone replacement therapies are reviewed; UF review not anticipated in the next 12 months.

Appendix C – Basic / Extended Core Formulary (BCF/ECF) Review

Drug Class or Potential Drug Class	BCF / ECF listing	Recommendation/ Rationale
Atypical antipsychotics	BCF – "Quetiapine"	• ER formulation (Seroquel XR) approved May 07; manufacturer willing to supply at no higher cost than IR quetiapine; no generics anticipated for some time (~2011). • Available in IR tabs (6 strengths), ER tabs (4 strengths). • Recommendation: • Clarify BCF listing to "Quetiapine tablets, immediate and extended release."
	BCF – "Risperidone oral; does not include orally disintegrating tablets (Risperdal Redi-tabs)"	• Oral dosage forms available: solution, tablets (6 strengths), rapidly disintegrating tablets (5 strengths) • Several manufacturers have tentative ANDAs listed for risperidone solution and tablets; patent expires Dec 2007, pediatric exclusivity ends Jun 2008. Unclear when orally disintegrating tablets will become generically available. • Recommendation: • Clarify BCF listing to "Risperidone tablets and solution, does not include orally disintegrating tablets."
Osteoporosis agents	BCF – "Alendronate 70 mg / vitamin D 2800 IU (Fosamax Plus D)"	• Alendronate 70 mg / vitamin D 5600 IU approved Apr 07; manufacturer willing to extend current pricing agreement for Fosamax Plus D; class to be reviewed soon. • 5600 IU combination recommended for "most" osteoporotic patients. • Recommendation • Clarify BCF listing to specify product with higher strength of vitamin D – "Alendronate 70 mg/vitamin D 5600 IU tablets."
Cough-cold medications	BCF – "Guaifenesin 600 / PSE 120 mg ER oral" (Entex LA generic)	• Guaifenesin containing timed release prescription products targeted for regulatory action by FDA in May 2007. • Companies expected to stop manufacturing unapproved products containing timed-release guaifenesin within 90 days and must cease shipping them in interstate commerce within 180 days. • Only guaifenesin products expected to remain on market are Adams' Labs over-the-counter products (e.g., Mucinex D). • Recommendation: • Remove listing from BCF.

Appendix D – Table of Abbreviations

ACE	angiotensin converting enzyme
ACR	American College of Rheumatology
ALT	alanine aminotransferase
APR	automated profile review
ARB	angiotensin receptor blocker
AR	allergic rhinitis
ARIA	Allergic Rhinitis and Its Impact on Asthma
AST	aspartate aminotransferase
BAP	Beneficiary Advisory Panel
BCF	Basic Core Formulary
BIA	budget impact analysis
BID	twice daily
BP	blood pressure
CEA	cost effectiveness analysis
CFR	Code of Federal Regulations
CI	confidence interval
CIU	chronic idiopathic urticaria
CMA	cost minimization analysis
CRI	chronic renal insufficiency
CYP	cytochrome (P450)
DERP	Drug Effectiveness Review Project (state of Oregon)
DoD	Department of Defense
EIB	exercise-induced bronchoconstriction
ER	extended release
ESI	Express Scripts, Inc.
FDA	Food and Drug Administration
FEV1	forced expiratory volume in 1 second
FY	fiscal year
GAD	generalized anxiety disorder
GH	growth hormone
GHD	growth hormone deficiency
GI	gastrointestinal
GSA	Growth Stimulating Agent (drug class)
HCTZ	hydrochlorothiazide
IGFD	insulin-like growth factor deficiency
ICS	inhaled corticosteroids
ISS	idiopathic short stature
LABA	long-acting beta agonists
LDL	low density lipoprotein
LFT	liver function test
LM	Leukotriene Modifier (drug class)
MAOI	monoamine oxidase inhibitor
MHS	Military Health System
MN	medical necessity
MTF	military treatment facility
NA	Newer Antihistamine (drug class)
NCS	nasal corticosteroids
NHLBI NAEPP	National Heart, Lung and Blood Institute National Asthma Education Prevention Program
OTC	over-the-counter
PA	prior authorization
PAR	perennial allergic rhinitis
P&T	Pharmacy and Therapeutics
PEC	Pharmacoeconomic Center

Appendix D – Table of Abbreviations (continued)

QD	once daily
QID	four times daily
RAAs	renin-angiotensin antihypertensive (drug class)
RCT	randomized controlled trial
RQLQ	rhinoconjunctivitis-specific quality of life
RR	relative risk
rTNSS	reflective Total Nasal Symptom Score
SAR	seasonal allergic rhinitis
SBS	Short bowel syndrome
SED-1	Sedative Hypnotic-1 (drug class)
SGA	small for gestational age
SHOX	Short Stature Homeobox gene
SNRI	serotonin norepinephrine reuptake inhibitor
SSRI	selective serotonin reuptake inhibitor
TCA	tricyclic antidepressant
TID	three times daily
TMA	TRICARE Management Activity
TMOP	TRICARE Mail Order Pharmacy
TNSS	Total Nasal Symptom Score
TRRx	TRICARE Retail Pharmacy Network
TS	Turner Syndrome
UF	Uniform Formulary
ULN	upper limit of normal

DECISION PAPER

DEPARTMENT OF DEFENSE

PHARMACY AND THERAPEUTICS COMMITTEE RECOMMENDATIONS

May 2007

1. **CONVENING**
2. **ATTENDING**
3. **REVIEW MINUTES OF LAST MEETING**
4. **ITEMS FOR INFORMATION**
5. **REVIEW OF RECENTLY APPROVED AGENTS**

A. Recently Approved Agents in Classes Not Yet Reviewed for the Uniform Formulary (UF) – The Pharmacy and Therapeutics (P&T) Committee was briefed on three new drugs which were approved by the Food and Drug Administration (FDA) (see Appendix B). The P&T Committee determined that these three new drugs fall into drug classes that have not yet been reviewed for UF status; therefore, UF consideration was deferred until drug class reviews are completed. The P&T Committee discussed the need for quantity limit (QL) or prior authorization (PA) requirements for the drugs (see paragraph 5A on pages 19-20 of the P&T Committee minutes).

COMMITTEE ACTION: QL RECOMMENDATIONS

- Arformoterol (Brovana) –The P&T Committee voted (13 for, 0 opposed, 1 abstained, 3 absent) to recommend QLs for arformoterol of 60 unit dose vials per 30 days, 180 unit dose vials per 90 days.
- Lapatinib (Tykerb) – The P&T Committee voted (14 for, 0 opposed, 1 abstained, 2 absent) to recommend QLs for lapatinib as follows: 150 tablets per 30 days at retail network pharmacies, with a days supply limit of 30 days (no multiple fills for multiple co-pays); and 225 tablets per 45 days at mail order, with a days supply limit of 45 days.
- Vorinostat (Zolinza) – The P&T Committee voted (14 for, 0 opposed, 1 abstained, 2 absent) to recommend QLs for vorinostat as follows: 120 tablets per 30 days at retail network pharmacies, with a days supply limit of 30 days (no multiple fills for multiple co-pays); and 180 tablets per 45 days at mail order, with a days supply limit of 45 days.

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

B. Over-the-Counter Terbinafine 1% Cream (Lamisil AT) – The John Warner National Defense Authorization Act for FY 2007 directs the Secretary of Defense to conduct a demonstration project to assess the impact of authorizing TRICARE coverage for over-the-counter (OTC) agents recommended for inclusion on the UF. The DoD P&T Committee must find that the OTC drug is cost effective and therapeutically equivalent to a prescription drug. The P&T Committee, after consultation with the TRICARE Management Activity (TMA) Pharmacy Program Office, selected the topical antifungal terbinafine 1% cream OTC (Lamisil AT) as the second OTC product for the demonstration.

The P&T Committee reviewed the topical antifungal drug class in May 2005. Topical antifungals on the UF include clotrimazole (Lotrimin, generics), nystatin (Mycostatin, generics), miconazole (Monistat Derm, generics), ketoconazole (Nizoral, generics), butenafine (Mentax), and naftifine (Naftin). Clotrimazole (Lotrimin, generics) and nystatin (Mycostatin, generics) are classified as Basic Core Formulary (BCF) agents. Topical antifungal agents classified as non-formulary under the UF are econazole (Spectazole, generics), sertaconazole (Ertaczo), sulconazole (Exelderm), ciclopirox (Loprox, generics; excludes ciclopirox topical solution (Penlac) for onychomycosis), oxiconazole (Oxistat) and 0.25% miconazole/15% zinc oxide (Vusion).

Relative Clinical Effectiveness – The P&T Committee concluded (14 for, 0 opposed, 1 abstained, 2 absent) that terbinafine 1% cream OTC has no clinically significant differences with respect to safety, efficacy, or tolerability, when compared to other allylamines included on the UF (butenafine and naftifine). The P&T Committee also concluded that it was unlikely that clinically significant differences exist between OTC terbinafine and the other prescription allylamines for the treatment of common dermatologic infections.

Relative Cost Effectiveness – Based on the results of the cost analysis and other clinical and cost considerations, the P&T Committee voted (14 for, 0 opposed, 1 abstained, 2 absent) that terbinafine 1% cream OTC is more cost effective than other allylamines in the topical antifungal class (butenafine and naftifine) across all three points of service.

COMMITTEE ACTION: UF RECOMMENDATION –Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations, and other relevant factors, the P&T Committee, based upon its collective professional judgment, voted (14 for, 0 opposed, 1 abstained, 2 absent) to recommend that terbinafine 1% cream OTC be classified as formulary on the UF (see paragraph 5B on pages 20-22 of the P&T Committee minutes).

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

6. DRUG CLASS REVIEW – ANTILIPIDEMIC II AGENTS (LIP-2s)

The P&T Committee evaluated the relative clinical effectiveness of the Antilipidemic II (LIP-2) agents. This class is divided into three subclasses: fibric acid derivatives, omega-3 fatty acids, and bile acid sequestrants (BAS). The fibric acid derivatives available commercially include gemfibrozil (Lopid, generics) and several formulations of fenofibrate (Tricor, Lofibra, Antara, and Triglide). Omega-3 fatty acid ("fish oil") products include the prescription product Omacor, along with a number of nutritional supplement products available OTC. Of these, only Omacor is eligible for inclusion on the UF. The BAS class consists of cholestyramine/sucrose (Questran, generics), cholestyramine/aspartame (Questran Light, generics), colestipol (Colestid, generics), and the newest agent, colesevelam (Welchol).

The LIP-2 drug class accounted for $63 million in Military Health System (MHS) expenditures in FY 2006, ranking in the top 20 in terms of total expenditures.

Relative Clinical Effectiveness Conclusion: The P&T Committee voted (15 for, 0 opposed, 0 abstained, 2 absent) to accept the following clinical effectiveness conclusion:

1) Fibric acid derivatives

   a) Both gemfibrozil and fenofibrate reduce triglycerides (TG) by 20-50% and raise high density lipoprotein (HDL) by 10-20%. There is insufficient evidence to conclude that gemfibrozil and fenofibrate differ in their ability to reduce TG and raise HDL.

   b) Two placebo-controlled trials with gemfibrozil have shown a benefit in reducing the risk of cardiovascular events in a primary prevention setting and the risk of nonfatal myocardial infarction (MI) and coronary heart disease (CHD) death in a secondary prevention setting. Mixed results were demonstrated with fenofibrate in a large outcomes trial in a primary/secondary prevention setting; fenofibrate did not result in a statistically significant benefit in reducing the composite of CHD death or nonfatal MI, but was associated with significant reductions in nonfatal MI ($p=0.01$) and coronary revascularization ($p=0.035$).

   c) Although gastrointestinal (GI) adverse effects occurred in fewer than 5% of patients taking fibric acid derivatives, they appeared to occur more frequently in patients taking gemfibrozil than those taking fenofibrate, based on pooled data from product labeling. Gemfibrozil must be taken twice daily prior to meals.

   d) Monotherapy with either fibric acid derivatives or statins has been associated with an increased risk of myalgia, myositis, and rhabdomyolysis. This risk appears to be increased with gemfibrozil/statin combination therapy, based on spontaneous adverse event reporting data from the FDA. These data showed a higher reporting rate of rhabdomyolysis with a statin plus gemfibrozil (8.6) compared to a statin plus fenofibrate (0.58), based on the number of spontaneous case reports per 1 million U.S. prescriptions from 1998 to 2002. This study excluded cerivastatin, which has now been withdrawn from the market. Limitations include varying definitions of myotoxicity, lack of verification of data, and the use of spontaneous reporting rates, which are subject to reporting bias and do not establish a causal relationship. It is unclear whether combination therapy with fenofibrate and a

statin increases the risk of myotoxicity more than either agent given alone. One trial comparing statin monotherapy vs. combination therapy with fenofibrate plus a statin reported similar rates of myalgia.

e) Pharmacokinetic differences in glucuronidation pathways between gemfibrozil and fenofibrate are postulated to account for potential differences in the risk of developing myotoxicity when used in combination with a statin. However, there are no head-to-head trials supporting a lower risk of myotoxicity with gemfibrozil than with fenofibrate, either alone or in combination with a statin, and professional organizations have not favored one fibric acid derivative over the other. The most recent joint guidelines (2003) from the American College of Cardiology, the American Heart Association, and the National Heart Lung and Blood Institute conclude that there is a risk with all fibric acid derivative/statin combinations, not just gemfibrozil plus statins.

f) Fenofibrate formulations include nanocrystallized fenofibrate (Tricor), micronized fenofibrate (Antara), insoluble drug delivery microparticle (IDD-P) fenofibrate (Triglide) and generic formulations of non-micronized and micronized fenofibrate (Lofibra). These newer formulations, regardless of dosage strength or particle size, are bioequivalent to 200 mg of the original fenofibrate formulation. Changes in particle size are designed to address bioavailability issues, allowing the most recent products (Tricor, Antara and Triglide) to offer once daily dosing and be taken without regard to meals. There is insufficient evidence to conclude that newer formulations offer improved efficacy, safety, or tolerability compared to each other or to older formulations.

2) Omega-3 Fatty Acids (Omacor)

a) Omacor is the only prescription omega-3 fatty acid product approved by the FDA. FDA oversight of the manufacturing process for Omacor offers increased assurance of its omega-3 fatty acid content and purity, in contrast to some fish oil supplements.

b) Overall, Omacor decreases TG by 20-45%. However, Omacor has also been associated with increases in low density lipoprotein (LDL), which may offset beneficial reductions in TG.

c) The TG-lowering effects of Omacor are slightly lower than those achieved with fibric acid derivatives or niacin. Omacor is associated with similar increases in HDL compared to fibric acid derivatives and niacin. Niacin and gemfibrozil both have clinical trial evidence supporting long-term benefits on cardiovascular outcomes.

d) The omega-3 fatty acid formulation found in Omacor does not have outcomes studies that demonstrate beneficial cardiovascular effects (e.g., reductions in cardiovascular death, MI or stroke).

3) Bile Acid Sequestrants

a) The BAS agents reduce LDL by 15 to 30%. This subclass has largely been replaced by the statins, which reduce LDL by 18% to 55%. There is insufficient evidence to conclude that BAS differ in their ability to lower LDL.

Cholestyramine is the only BAS to show beneficial effects on cardiovascular outcomes.

b) Colesevelam has no major efficacy advantages compared to cholestyramine or colestipol, despite manufacturer claims of enhanced bile acid binding capacity. It has a more favorable pregnancy category rating than the older products (B vs. C) and may cause less constipation, which may be clinically relevant in patients with a previous history of GI obstruction.

c) Issues with palatability of powder formulations and/or large daily tablet burdens are a concern with the class as a whole and may affect compliance.

d) The BAS agents have a high degree of therapeutic interchangeability.

Overall Clinical Effectiveness Conclusion – Based on clinical issues alone, there are no compelling reasons to classify any of the LIP-2 agents as non-formulary under the UF.

Relative Cost Effectiveness Conclusion: Based on the results of the pharmacoeconomic analyses and other clinical and cost considerations, the DoD P&T Committee voted (15 for, 0 opposed, 0 abstained, and 2 absent) that:

1) Gemfibrozil was the most cost-effective fibric acid derivative evaluated. Of the various fenofibrate formulations, IDD-P fenofibrate demonstrated the best cost effectiveness profile.

2) Colesevelam was recognized as not cost effective in the treatment of hyperlipidemia compared to other BAS.

3) In the management of hypertriglyceridemia, Omacor was identified as not cost-effective compared to gemfibrozil, fenofibrate, and niacin.

4) The UF scenario that maintained fenofibrate, IDD-P fenofibrate, cholestyramine/ aspartame, cholestyramine/sucrose, colestipol, and gemfibrozil on the UF was the most cost effective UF scenario.

A. COMMITTEE ACTION: UF RECOMMENDATION – Taking into consideration the conclusions from the relative clinical effectiveness and the relative cost effectiveness determinations for the LIP-2s, and other relevant factors, the P&T Committee recommended (13 for, 1 opposed, 1 abstained, 2 absent) that: 1) fenofibrate, IDD-P fenofibrate, cholestyramine/aspartame, cholestyramine/sucrose, colestipol, and gemfibrozil be maintained as formulary on the UF; 2) micronized fenofibrate (Antara), nanocrystallized fenofibrate, colesevelam, and Omacor be classified as non-formulary under the UF; and 3) the normal brand formulary cost-share of $9.00 for IDD-P fenofibrate (Triglide) be lowered to the generic formulary cost-share of $3.00 (see paragraphs 6A, 6B, and 6C on pages 22-37 of the P&T Committee minutes).

The authority for the last recommendation is codified in 32 CFR 199.21(j)(3), which states that “when a blanket purchase agreement, incentive price agreement, Government contract, or other circumstances results in a brand pharmaceutical agent being the most cost effective agent for purchase by the Government, the P&T Committee may also designate that the drug be cost-shared at the generic rate.” The objective is to maximize use of IDD-P fenofibrate in the retail network and mail

order, given its significantly lower cost relative to other fenofibrate products. Lowering the cost-share for brand name IDD-P fenofibrate will provide a greater incentive for beneficiaries to use the most cost effective fenofibrate formulation in the purchased care arena.

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

B. COMMITTEE ACTION: MEDICAL NECESSITY (MN) CRITERIA – Based on the clinical evaluation and the conditions for establishing MN for a non-formulary medication provided for in the UF rule, the P&T Committee recommended (13 for, 1 opposed, 1 abstained, 2 absent) general MN criteria for micronized fenofibrate (Antara), nanocrystallized fenofibrate, colesevelam, and Omacor (see paragraph 6D on page 37 of the P&T Committee minutes).

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

C. COMMITTEE ACTION: IMPLEMENTATION PERIOD – The P&T Committee recommended (14 for, 0 opposed, 1 abstained, 2 absent) an effective date of the first Wednesday following a 90-day implementation period. The implementation period will begin immediately following the approval by the Director, TMA (see paragraph 6E on pages 37-38 of the P&T Committee minutes).

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows: for 120 days

D. COMMITTEE ACTION: BCF RECOMMENDATION – Based on the results of the clinical and economic evaluations presented, the P&T Committee voted (14 for, 0 opposed, 1 abstained, 2 absent) to recommend that gemfibrozil and IDD-P fenofibrate (Triglide) be designated as the BCF selections in this class (see paragraph 6F on page 38 of the P&T Committee minutes).

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

7. DRUG CLASS REVIEW – 5-ALPHA REDUCTASE INHIBITORS (5-ARIs)

The P&T Committee evaluated the relative clinical effectiveness of the 5-alpha reductase inhibitor agents (5-ARIs). The 5-ARI drug class includes finasteride (Proscar, generics) and dutasteride (Avodart). Both have been approved by the FDA for the treatment of symptomatic benign prostatic hyperplasia (BPH) in men with an enlarged prostate.

The 5-ARI drug class accounted for $31.2 million in MHS expenditures for FY 2006 and is ranked #50 in terms of total expenditures. More than 281,000 prescriptions for 5-ARIs

were filled in the MHS during a one-year period (January 2006 to December 2006). Of these, 59% were for finasteride and 41% were for dutasteride.

Relative Clinical Effectiveness Conclusion: The P&T Committee voted (15 for, 0 opposed, 0 abstained, 2 absent) to accept the following clinical effectiveness conclusion:

1) There is insufficient evidence to conclude that there are significant differences in efficacy between finasteride and dutasteride. Indirect comparisons from long-term efficacy trials suggest similar decreases in total prostate volume, increases in urinary flow rate, improvement in symptoms, and similar reductions in the risk of acute urinary retention and BPH-related surgery.
2) The only fully published head-to-head trial suggests that dutasteride therapy reduces serum dihydrotestosterone levels by 95%, compared to 71% with finasteride. The clinical significance of this finding has yet to be determined. This 24-week trial contributes no useful comparative data concerning long-term efficacy. A large but as yet unpublished head-to-head trial (the Enlarged Prostate International Comparator Study) reported no differences in efficacy outcomes with finasteride vs. dutasteride after one year of treatment.
3) There is insufficient evidence to compare the two agents when used in combination with alpha blockers. More data are available with finasteride than with dutasteride, including a long-term trial with finasteride and doxazosin (the Medical Therapy of Prostatic Symptoms trial); there are no published long-term combination trials with dutasteride.
4) The overall effect of 5-ARIs on prostate cancer prevention is unclear.
5) There appear to be few differences in the incidence of adverse effects with finasteride or dutasteride, based on placebo-controlled trials and limited comparative data. Both agents are well tolerated. The most common adverse effects are related to sexual dysfunction; they diminish with chronic dosing.
6) Reported withdrawal rates due to adverse effects are low in clinical trials of finasteride and dutasteride, similar during the first year of therapy, and decrease further with both agents during continued treatment.
7) There are no major differences between finasteride and dutasteride with regard to use in special populations or drug interactions.
8) Neither agent appears to interfere with prostate cancer detection.
9) Finasteride and dutasteride appear to have a high degree of therapeutic interchangeability; either could be expected to meet the needs of the majority of DoD BPH patients.

Relative Cost Effectiveness Conclusion: Based on the results of the cost minimization analysis (CMA) and other clinical and cost considerations, the DoD P&T Committee voted (15 for, 0 opposed, 0 abstained, and 2 absent) that:

1) Finasteride was the most cost effective agent, with a lower cost per day of treatment than dutasteride across all condition sets evaluated.

2) A cost-effectiveness analysis that evaluated the cost per BPH surgery averted showed that finasteride was the preferred choice with a lower expected cost per surgery averted than dutasteride.

3) The UF scenario that placed finasteride as the sole 5-ARI on the UF was the most cost effective scenario.

A. COMMITTEE ACTION: UF RECOMMENDATION – Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of the 5-ARIs, and other relevant factors, the P&T Committee, based upon its collective professional judgment, voted (14 for, 0 opposed, 1 abstained, 2 absent) to recommend that: 1) finasteride be classified as formulary on the UF, and 2) that dutasteride be classified as non-formulary under the UF (see paragraphs 7A, 7B, and 7C on pages 38-44 of the P&T Committee minutes).

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

B. COMMITTEE ACTION: MN CRITERIA – Based on the clinical evaluation for dutasteride and the conditions for establishing MN for a non-formulary medication provided for in the UF rule, the P&T Committee recommended (14 for, 0 opposed, 1 abstained, 2 absent) MN criteria for dutasteride (see paragraph 7D on page 44 of the P&T Committee minutes).

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

C. COMMITTEE ACTION: IMPLEMENTATION PERIOD – The P&T Committee voted (14 for, 0 opposed, 1 abstained, 2 absent) to recommend an effective date of the first Wednesday following a 90-day implementation period. The implementation period will begin immediately following approval by the Director, TMA (see paragraph 7E on pages 44-45 of the P&T Committee minutes).

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

D. COMMITTEE ACTION: BCF RECOMMENDATION – Based on the relative clinical effectiveness and cost effectiveness analyses, the P&T Committee voted (14 for, 0 opposed, 1 abstained, 2 absent) to recommend designating finasteride as the BCF selection in this class (see paragraph 7F on page 45 of the P&T Committee minutes).

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

8. DRUG CLASS REVIEW – PROTON PUMP INHIBITORS (PPIs)

The P&T Committee evaluated the relative clinical effectiveness of the PPIs. The PPI drug class includes the following agents: esomeprazole (Nexium), lansoprazole (Prevacid), omeprazole (Prilosec and generics), omeprazole/sodium bicarbonate (Zegerid), omeprazole magnesium (Prilosec OTC), pantoprazole (Protonix), and rabeprazole (Aciphex). Omeprazole magnesium (Prilosec OTC) was added to the UF for purposes of the OTC Demonstration Project as a result of the February 2007 P&T Committee meeting.

PPIs have become the standard of care for treatment of acid-related gastrointestinal disorders. As of March 07, about 350,000 MHS prescriptions for PPIs are filled per month. This drug class has now taken over the #1 spot in terms of MHS expenditures: more than $485 million over the 12 months from April 2006 to March 2007, compared to about $350 million in FY 2005. Military treatment facility (MTF) pharmacies dispense 47% of all PPI tablets, compared to 36% dispensed by retail network pharmacies and 17% dispensed by the TRICARE Mail Order Pharmacy (TMOP). Across the MHS, rabeprazole is the most commonly prescribed PPI, due mainly to its favorable formulary status and high utilization at MTFs. The next four most-prescribed PPIs – lansoprazole, esomeprazole, pantoprazole, and omeprazole – have similar utilization patterns. Of the PPIs, only prescription omeprazole is generically available.

Relative Clinical Effectiveness Conclusion: The P&T Committee voted (15 for, 0 opposed, 0 abstained, 2 absent) to accept the following clinical effectiveness conclusion:

1) Based on head-to-head and other controlled trials, PPIs have similar efficacy in a wide range of acid related disorders and are highly therapeutically interchangeable.

2) Although some trials appear to demonstrate superior efficacy for healing of erosive esophagitis (EE) with esomeprazole, actual differences are small and inconsistent among trials. Evidence for clinical efficacy is similar enough to consider all agents equally effective in healing of EE.

3) There is sufficient evidence to support the use of PPIs for maintenance of initial healing and symptomatic relief of EE for as long as five years. However, the evidence is insufficient to conclude that one PPI is superior to the others for maintenance of EE healing.

4) There appear to be no comparative differences among PPIs for healing, maintenance of healing, or symptom improvement in peptic ulcer disease and/or non-steroidal anti-inflammatory drug (NSAID) induced ulcers.

5) Based on available clinical trials, PPIs appear to be similarly efficacious in the short-term treatment of endoscopy-negative reflux disease (ENRD); there are insufficient data to draw conclusions regarding efficacy for long-term or on-demand treatment.

6) *H. pylori* eradication rates appear similar among PPIs when differing doses of antibiotics and treatment duration are taken into account.

7) There are insufficient data to suggest superiority of one PPI over the others for treatment of pediatric patients; omeprazole, lansoprazole, and esomeprazole have FDA indications for use in pediatric patients.

8) The class as a whole is well-tolerated, with an adverse effect profile similar to placebo; most drug interactions are minor in nature. In general, PPIs appear very similar with respect to safety and tolerability.

9) Minor differences include the lack of a requirement to adjust the dose of pantoprazole (Protonix) in patients with severe hepatic disease (unlike other PPIs); a less favorable pregnancy category rating for omeprazole than the more recently introduced PPIs (C vs. B); and the availability of liquid dosage forms for esomeprazole, lansoprazole, and omeprazole/sodium bicarbonate.

Relative Cost Effectiveness Conclusion: Based on the results of the CMAs and other clinical and cost considerations, the P&T Committee voted (14 for, 0 opposed, 0 abstained, 3 absent) that:

1) The CMA of each potential UF scenario showed that, as expected, the more restrictive the UF scenario, the lower the cost per day of treatment.

2) Among UF scenarios with two agents on the UF, omeprazole and esomeprazole were the most cost effective option.

3) Among UF scenarios with three to four agents on the UF, omeprazole, esomeprazole, pantoprazole, and rabeprazole were the most cost effective agents.

4) The UF scenario that maintained omeprazole and esomeprazole as the only two agents on the UF in conjunction with a PA requiring a trial of either agent for new patients was the most cost effective scenario.

A. COMMITTEE ACTION: UF RECOMMENDATION – Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of the PPIs, and other relevant factors, the P&T Committee, based upon its collective professional judgment, voted (14 for, 0 opposed, 1 abstained, and 2 absent) to recommend that: 1) omeprazole and esomeprazole be maintained as formulary on the UF with a PA requiring a trial of either agent for new patients; 2) that rabeprazole, lansoprazole, pantoprazole, and omeprazole/sodium bicarbonate be classified as non-formulary under the UF with a PA requiring a trial of either omeprazole or esomeprazole for new patients; and 3) that the normal brand formulary cost-share of $9.00 for esomeprazole be lowered to the generic formulary cost-share of $3.00.

The authority for the last recommendation is codified in 32 CFR 199.21(j)(3), which states that "when a blanket purchase agreement, incentive price agreement, Government contract, or other circumstances results in a brand pharmaceutical agent being the most cost effective agent for purchase by the Government, the P&T may also designate that the drug be cost-shared at the generic rate." Lowering the cost-share for brand name esomeprazole will provide a greater incentive for beneficiaries to use esomeprazole rather than the less cost effective branded products – rabeprazole, lansoprazole, pantoprazole, or omeprazole/sodium bicarbonate – in the

purchased care arena (see paragraphs 8A, 8B, and 8C on pages 46-53 of the P&T Committee minutes).

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

B. COMMITTEE ACTION: PA CRITERIA

The P&T Committee voted (14 for, 0 opposed, 1 abstained, 2 absent) that the following PA criteria should apply to PPIs other than omeprazole or esomeprazole. Coverage would be approved if a patient met any of the following criteria:

1) Automated PA criteria:
   a) The patient has received a prescription for any PPI agent at any MHS pharmacy point of service (MTFs, retail network pharmacies, or mail order) during the previous 180 days.
2) PA criteria if automated criteria are not met:
   a) The patient has tried omeprazole or esomeprazole and had an inadequate response or was unable to tolerate treatment due to adverse effects.
   b) Treatment with omeprazole or esomeprazole is contraindicated.

(See paragraph 8D on pages 53-54 of the P&T Committee minutes.)

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

C. COMMITTEE ACTION: MN CRITERIA – Based on the clinical evaluation and the conditions for establishing MN for a non-formulary medication provided for in the UF rule, the P&T Committee recommended (14 for, 0 opposed, 1 abstained, 2 absent) MN criteria for rabeprazole, lansoprazole, pantoprazole, and omeprazole/sodium bicarbonate (see paragraph 8E on page 54 of the P&T Committee minutes).

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

D. COMMITTEE ACTION: IMPLEMENTATION PERIOD – The P&T Committee voted (14 for, 0 opposed, 1 abstained, 2 absent) to recommend an effective date of the first Wednesday following a 90-day implementation period. The implementation period will begin immediately following approval by the Director, TMA (see paragraph 8F on page 54 of the P&T Committee minutes).

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

E. COMMITTEE ACTION: BCF RECOMMENDATION – Based on the relative clinical effectiveness and cost effectiveness analyses, the P&T Committee voted (14 for, 0 opposed, 1 abstained, 2 absent) to recommend designating generic omeprazole (Prilosec 40 mg specifically omitted) and esomeprazole as the BCF selections in this class (see paragraph 8G on page 55 of the P&T Committee minutes).

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

9. DRUG CLASS REVIEW – ANGIOTENSIN RECEPTOR BLOCKERS (ARBs)

The P&T Committee evaluated the relative clinical effectiveness of the seven angiotensin receptor blockers (ARBs) marketed in the U.S. The ARB drug class is comprised of losartan (Cozaar), irbesartan (Avapro), valsartan (Diovan), candesartan (Atacand), telmisartan (Micardis), eprosartan (Teveten), olmesartan (Benicar) and their respective combinations with hydrochlorothiazide (HCTZ).

Utilization of the ARBs has been steadily increasing in the MHS. The ARB drug class accounted for $137 million in MHS expenditures in FY 2006, and is ranked #10 in terms of total expenditures during that time period.

The P&T Committee focused on efficacy differences with respect to labeled indications, particularly in those areas where a benefit in clinical outcomes (e.g., death, hospitalization for heart failure, decreased need for dialysis or renal transplantation) was demonstrated. The primary areas evaluated were efficacy for hypertension, chronic heart failure, and type 2 diabetic nephropathy.

Relative Clinical Effectiveness Conclusion: The P&T Committee voted (15 for, 0 opposed, 0 abstained, 2 absent) to accept the following clinical effectiveness conclusion:

1) There is no evidence that any one ARB is more efficacious than the others for lowering blood pressure.
2) Although losartan is labeled to reduce the risk of stroke in patients with left ventricular hypertrophy (LVH), Joint National Commission (JNC) guidelines support use of other antihypertensive drugs (e.g., angiotensin converting enzyme (ACE) inhibitors, diuretics) in this setting. Differences in blood pressure reduction largely account for differences in cardiovascular outcomes seen in trials comparing ARBs to other antihypertensives.
3) There is no evidence to support clinically significant differences in efficacy between candesartan and valsartan in reducing heart failure (HF) hospitalizations in patients with chronic HF.
4) There is no evidence to support clinically significant differences in efficacy between irbesartan and losartan in improving clinical outcomes (e.g., reducing the risk of doubling of serum creatinine, death, or development of end stage renal disease) in patients with type 2 diabetic nephropathy.
5) Valsartan is the only ARB labeled to reduce death and development of heart failure in post-MI patients with left ventricular systolic dysfunction (LVSD).

However, ACE inhibitors have a larger body of evidence supporting a mortality benefit in post-MI patients with LVSD than valsartan. The aldosterone antagonists spironolactone (Aldactone, generics) and eplerenone (Inspra) are also labeled for use or have shown efficacy in the post-MI setting.

6) There is no evidence that the ARBs differ significantly with regard to safety and tolerability profiles.

7) Based on clinical issues alone, there are no compelling reasons to classify any of the ARBs as nonformulary under the UF.

Relative Cost Effectiveness Conclusion: Based on the results of the CMAs and other clinical and cost considerations, the Committee voted (15 for, 0 opposed, 0 abstained, and 2 absent) that:

1) A UF scenario with three or fewer agents on the UF was more cost effective than scenarios that included additional agents on the UF.

2) Telmisartan was the most cost effective agent for the management of hypertension; candesartan was more cost effective for management of chronic HF than valsartan; losartan and irbesartan had similar cost effectiveness profiles for treatment of type 2 diabetic nephropathy.

3) The UF scenario that included candesartan, candesartan/HCTZ, losartan, losartan/HCTZ, telmisartan, and telmisartan/HCTZ was the most cost effective UF scenario evaluated.

A. COMMITTEE ACTION: UF RECOMMENDATION – In view of the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of the ARBs, and other relevant factors, the P&T Committee, based upon its collective professional judgment, voted (14 for, 0 opposed, 1 abstained, and 2 absent) to recommend that candesartan, candesartan/HCTZ, losartan, losartan/HCTZ, telmisartan, and telmisartan/HCTZ be maintained as formulary on the UF and that eprosartan, eprosartan/HCTZ, irbesartan, irbesartan/HCTZ, olmesartan, olmesartan/HCTZ, valsartan and valsartan/HCTZ be classified as non-formulary under the UF (see paragraphs 9A, 9B, and 9C on pages 55-61 of the P&T Committee minutes).

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

B. COMMITTEE ACTION: MN CRITERIA – Based on the clinical evaluation and the conditions for establishing MN for a non-formulary medication provided for in the UF rule, the P&T Committee recommended (13 for, 1 opposed, 1 abstained, 2 absent) general MN criteria for eprosartan, eprosartan/HCTZ, irbesartan, irbesartan/HCTZ, olmesartan, olmesartan/HCTZ, valsartan and valsartan/HCTZ (see paragraph 9D on pages 61-62 of the P&T Committee minutes).

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

C. COMMITTEE ACTION: IMPLEMENTATION PERIOD – The P&T Committee recommended (14 for, 0 opposed, 1 abstained, 2 absent) an effective date of the first Wednesday following a 120-day implementation period. The implementation period will begin immediately following the approval by the Director, TMA (see paragraph 9E on pages 62 of the P&T Committee minutes).

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

D. COMMITTEE ACTION: BCF RECOMMENDATION – Based on the results of the clinical and economic evaluations, the P&T Committee voted (14 for, 0 opposed, 1 abstained, and 2 absent) to recommend that telmisartan and telmisartan/HCTZ remain on the BCF (see paragraph 9F on page 62 of the P&T Committee minutes).

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows

10. QUANTITY LIMITS

The P&T Committee agreed that current QLs for two nasal inhalers should be increased, based on daily maximum doses recommended in product labeling and increases in QL override requests based on higher dosing consistent with labeling (see paragraph 10 on pages 63-64 of the P&T Committee minutes).

COMMITTEE ACTION: QL RECOMMENDATIONS

- Mometasone nasal spray (Nasonex) – The Committee voted (14 for, 0 opposed, 1 abstained, and 2 absent) to recommend that the QL for mometasone nasal spray (Nasonex) be increased to 34 gm (2 inhalers) per 30 days (retail network pharmacies), 102 gm (6 inhalers) per 90 days (mail order), based on daily maximum dosing recommended in product labeling.
- Ipratropium nasal spray (Atrovent) – The Committee voted (13 for, 0 opposed, 2 abstained, and 2 absent) to recommend that 1) the QL for ipratropium nasal spray (Atrovent) be changed from a collective limit to a QL by strength; 2) the QL for the 0.03% strength be increased to 2 inhalers (60 mL) per 30 days (retail network pharmacies), 6 inhalers (180 mL) per 90 days (mail order); and 3) the QL for the 0.06% strength be increased to 3 inhalers (45 mL) per 30 days (retail network pharmacies), 9 inhalers (135 mL) per 90 days (mail order), based on daily maximum dosing recommended in product labeling.

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

11. RE-EVALUATION OF NON-FORMULARY AGENTS

Amlodipine (Norvasc) was designated non-formulary at the August 2005 P&T Committee meeting. In early 2007, the FDA approved Mylan Pharmaceutical's first-time generic for Norvasc (amlodipine, Pfizer). The price of amlodipine remains high enough that the Committee felt that even the generic was not cost effective relative to other drugs in the calcium channel blocker class. However, as part of its re-evaluation of the non-formulary UF status of amlodipine, the P&T Committee recognized that there will be situations in the future in which it would be helpful if a procedure were in place that allowed reclassification of such a drug from non-formulary to generic in a more expeditious manner than can be accomplished through the normal quarterly P&T Committee cycle. Such a procedure would be advantageous for both the MHS and its beneficiaries. The P&T Committee proposed the following process to more expeditiously reclassify non-formulary agents:

1) For each drug class in which such a reclassification is a possibility, the P&T Committee will recommend criteria under which non-formulary agents will be reclassified as generic agents on the UF. These criteria will be reviewed and adopted as a recommendation of the committee. The recommendation will be subject to comment by the Beneficiary Advisory Panel (BAP), and final decision by the Director, TMA (see recommended criteria below).
2) When the pre-established criteria for reclassification are met, the Chairperson of the P&T Committee will call for an electronic vote by the members of the P&T Committee on the matter.
3) Upon a majority vote affirming that the non-formulary drug should be reclassified as generic, that agent will be changed from non-formulary status to formulary status as a generic.
4) Committee members will be briefed on any reclassification of a non-formulary agent at the next meeting of the P&T Committee. This information will be recorded as an information-only item in the meeting minutes. The item will be included in information provided for the BAP's next meeting; however, since the BAP will have already made any comments on the subject, it is not expected the item will normally generate further BAP comment.

The DoD P&T Committee recommended the following criteria for the re-evaluation of non-formulary agents for UF status. These criteria would apply only to drug classes in which UF status was NOT awarded based on condition sets that specified the number of similar agents on the UF (i.e., agents in the same class or subclass). All three criteria must be met for the reclassification of a non-formulary agent.

1) The P&T Committee had concluded previously that the non-formulary agent had similar relative clinical effectiveness (i.e., similar efficacy, safety, and tolerability) compared to similar agents on the UF, and the drug had not been excluded from the UF based on clinical issues alone.
2) The non-formulary agent becomes generically available and:
    a) The generic product is "A-rated" as therapeutically equivalent to the brand name product according to the FDA's classification system

b) The generic market supply is stable and sufficient to meet DoD MHS supply demands.

3) The non-formulary agent is cost effective relative to similar agents on the UF. A non-formulary agent becomes cost-effective when:

a) The non-formulary agent's total weighted average cost per day of treatment is less than or equal to the total weighted average cost per day of treatment for the UF class to which they were compared.

b) The non-formulary agent's total weighted average cost based on an alternate measure used during the previous review is less than or equal to that for the UF class to which they were compared. For example, antibiotics may be compared on the cost per course of therapy used to treat a particular condition.

(See paragraph 11 on pages 64-65 of the P&T Committee minutes).

COMMITTEE ACTION: The P&T Committee recommended (14 for, 0 against, 3 absent) that the process and criteria described above should be adopted.

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

Department of Defense
Pharmacy and Therapeutics Committee Minutes
May 2007

1. CONVENING

The Department of Defense (DoD) Pharmacy and Therapeutics (P&T) Committee convened at 0800 hours on May 15-16, 2007 at the DoD Pharmacoeconomic Center (PEC), Fort Sam Houston, Texas.

2. ATTENDANCE

A. Voting Members Present

CAPT Patricia Buss, MC, USN	DoD P&T Committee Chair
LTC Brett Kelly, MSC, USA	DoD P&T Committee Recorder
CAPT William Blanche, MSC, USN	DoD Pharmacy Programs, TMA
Lt Col Roger Piepenbrink, MC	Air Force, Internal Medicine Physician
Capt Jeremy King, MC	Air Force, OB/GYN Physician
Lt Col Brian Crownover, MC	Air Force, Physician at Large
LCDR Ronnie Garcia, MC *for* LCDR Michelle Perrello, MC	Navy, Internal Medicine Physician
CDR David Tanen, MC	Navy, Physician at Large
CAPT David Price, MSC	Navy, Pharmacy Officer
COL Doreen Lounsbery, MC	Army, Internal Medicine Physician
MAJ Roger Brockbank, MC	Army, Family Practice Physician
COL David Estroff, MC *for* COL Ted Cieslak, MC	Army, Physician at Large
LTC Peter Bulatao, MSC *for* COL Isiah Harper, MSC	Army, Pharmacy Officer
CAPT Vernon Lew, USPHS	Coast Guard, Pharmacy Officer
Mr. Joe Canzolino, RPh.	Department of Veterans Affairs

B. Voting Members Absent

Col Everett McAllister, BSC	Air Force, Pharmacy Officer
LCDR Scott Akins, MC	Navy, Pediatrics Physician

C. Non-Voting Members Present

COL Kent Maneval, MSC, USA	Defense Medical Standardization Board
Lt Col Paul Hoerner, BSC, USAF	Deputy Director, DoD Patient Safety Center
CPT Alvin Blackmon, MSC, USA	Defense Supply Center Philadelphia
Mr. Lynn T. Burleson	Assistant General Counsel, TMA

D. Non-Voting Members Absent

LT Thomas Jenkins, MSC, USN	TMA Aurora
Martha Taft	Health Plans Operations, TMA

E. Others Present

Col Nancy Misel, BSC, USAF	IMA DoD Pharmacoeconomic Center
Lt Col James McCrary, MC, USAF	DoD Pharmacoeconomic Center
Maj Wade Tiller, BSC, USAF	DoD Pharmacoeconomic Center
Maj Josh Devine, BSC, USAF	DoD Pharmacoeconomic Center
LCDR Joe Lawrence, MSC, USN	DoD Pharmacoeconomic Center
CPT Josh Napier, MC, USA	DoD Pharmacoeconomic Center
Shana Trice, Pharm.D.	DoD Pharmacoeconomic Center
David Bretzke, Pharm.D.	DoD Pharmacoeconomic Center
Angela Allerman, Pharm.D.	DoD Pharmacoeconomic Center
Eugene Moore, Pharm.D.	DoD Pharmacoeconomic Center
Julie Liss, Pharm.D.	DoD Pharmacoeconomic Center
Elizabeth Hearin, Pharm.D.	DoD Pharmacoeconomic Center
David Meade, Pharm.D.	DoD Pharmacoeconomic Center
Harsha Mistry, Pharm.D.	DoD Pharmacoeconomic Center
Lisa Longo, Pharm.D.	VAPBM
Lisa McNair	TMA
LCDR Rob Hayes	DHHS, Indian Health Service

3. REVIEW MINUTES OF LAST MEETING

A. Corrections to the Minutes – February 2007 DoD P&T Committee meeting minutes were approved as written, with no corrections noted.

B. Approval of February Minutes – MG Elder Granger, USA, MC, Deputy Director, TMA, approved the minutes of the February 2007 DoD P&T Committee meeting on May 2, 2007.

4. ITEMS FOR INFORMATION

TRICARE Management Activity (TMA) and DoD PEC staff members briefed the P&T Committee on the following:

A. Beneficiary Advisory Panel (BAP) Briefing – CAPT Buss briefed the members of the P&T Committee regarding the March 2007 BAP meeting. The P&T Committee was briefed on BAP comments regarding the DoD P&T Committee's Uniform Formulary (UF) and implementation recommendations.

B. Implementation Status of UF Decisions – The PEC briefed the members of the P&T Committee on the progress of implementation for drug classes reviewed for UF status since February 2005.

C. Administrative Action – Modification of Modafinil (Provigil) Prior Authorization (PA) Criteria – A PA for modafinil (Provigil) was recommended by the P&T Committee at the November 2006 meeting and subsequently approved by the Director, TMA, with an effective date of April 18, 2007. The PEC briefed the members of the P&T Committee on an administrative action to omit the PA criterion addressing use for cocaine dependence from PA criteria posted on the TRICARE Pharmacy website and incorporated into PA forms. The criterion provided for coverage of modafinil for cocaine dependence, based on two randomized trials supporting the use of modafinil for the treatment of cocaine dependency. (One trial reported decreased euphoria with cocaine use, the other an increased abstinence rate; modafinil is thought to counteract the glutamate-depleting effect of cocaine, possibly reducing craving.) The criterion was administratively omitted because coverage of substance abuse treatment in settings other than authorized institutional providers falls under another TRICARE approval process and is affected by other TRICARE regulations, not because of clinical considerations. The P&T Committee concurred with the change.

5. REVIEW OF RECENTLY APPROVED AGENTS

A. Recently Approved Agents in Classes Not Yet Reviewed for the UF

The P&T Committee was briefed on three new drugs which were approved by the Food and Drug Administration (FDA) (see Appendix B). The P&T Committee determined that these three new drugs fall into drug classes that have not yet been reviewed for UF status; therefore, UF consideration was deferred until drug class reviews are completed. The P&T Committee discussed the need for quantity limit (QL) or PA requirements for the drugs.

The P&T Committee agreed that the three new drugs required QLs, based on existing QLs for similar agents (oral cancer agents and products for oral inhalation) and recommendations for use in product labeling.

COMMITTEE ACTION: QLs

- Arformoterol (Brovana) – The P&T Committee voted (13 for, 0 opposed, 1 abstained, 3 absent) to recommend QLs for arformoterol (Brovana) of 60 unit dose vials per 30 days, 180 unit dose vials per 90 days.

- Lapatinib (Tykerb) – The P&T Committee voted (14 for, 0 opposed, 1 abstained, 2 absent) to recommend QLs for lapatinib (Tykerb) as follows: 150 tablets per 30 days at retail network pharmacies, with a days supply limit of 30 days (no multiple fills for multiple co-pays); and 225 tablets per 45 days at mail order, with a days supply limit of 45 days.
- Vorinostat (Zolinza) – The P&T Committee voted (14 for, 0 opposed, 1 abstained, 2 absent) to recommend QLs for vorinostat (Zolinza) as follows: 120 tablets per 30 days at retail network pharmacies, with a days supply limit of 30 days (no multiple fills for multiple co-pays); and 180 tablets per 45 days at mail order, with a days supply limit of 45 days.

B. Over-the-Counter (OTC) terbinafine 1% Cream (Lamisil AT)

Section 705 of the John Warner National Defense Authorization Act for Fiscal Year 2007 directs the Secretary of Defense to conduct a demonstration project under section 1092 of title 10, U.S. Code, to allow particular OTC drugs to be included on the UF under section 1074g of such title. The purpose is to assess the impact of authorizing TRICARE coverage for OTC agents recommended for inclusion on the UF. For an OTC drug to be included as part of the OTC Demonstration Project, the P&T Committee must find that the OTC drug is cost effective and therapeutically equivalent to a prescription drug. Beneficiaries will be required to have a prescription for the OTC product. OTC drugs provided under the demonstration project shall be made available through military treatment facilities (MTFs) and the TRICARE Mail Order Pharmacy (TMOP).

The P&T Committee, after consultation with the TMA Pharmacy Program office, selected the topical antifungal terbinafine 1% cream OTC (Lamisil AT) as the second OTC product for the project. Since this is the first opportunity for terbinafine 1% cream OTC to be considered for UF inclusion, it was reviewed as a new drug in a class previously reviewed.

The P&T Committee reviewed the topical antifungal drug class in May 2005. Topical antifungals on the UF include clotrimazole (Lotrimin, generics), nystatin (Mycostatin, generics), miconazole (Monistat Derm, generics), ketoconazole (Nizoral, generics), butenafine (Mentax), and naftifine (Naftin). Clotrimazole and nystatin are classified as Basic Core Formulary (BCF) agents. Topical antifungal agents classified as non-formulary under the UF are econazole (Spectazole, generics), sertaconazole (Ertaczo), sulconazole (Exelderm), ciclopirox (Loprox, generics; excludes ciclopirox topical solution (Penlac) for onychomycosis), oxiconazole (Oxistat) and 0.25% miconazole/15% zinc oxide (Vusion).

1) *Relative Clinical Effectiveness* – Terbinafine is a synthetic allylamine derivative that interferes with synthesis of the fungal cell wall. Terbinafine was originally available as a prescription product in 1992, but as of 1999 is solely available OTC. FDA-approved indications for terbinafine include tinea pedis, tinea cruris, and tinea corporis. Terbinafine is also effective for treating tinea versicolor, although it is not labeled for this indication. Dosing and administration vary with the indication; for tinea pedis, terbinafine is applied twice daily for seven days, or once daily for four weeks. For tinea versicolor, tinea corporis, or tinea cruris, the

recommended dosing is once daily for 14 days. Terbinafine 1% OTC is available in several different formulations, including cream, spray, and gel; only the cream is under consideration for UF inclusion.

Allylamines on the UF include butenafine (Mentax) and naftifine (Naftin). The allylamines, including terbinafine, appear to be slightly more efficacious than azoles for treatment of tinea pedis. A Cochrane analysis evaluated efficacy of the allylamines (terbinafine, naftifine) and azoles (clotrimazole, econazole, miconazole, and sulconazole) for treating tinea pedis. Pooled analyses of trials comparing azoles with allylamines yielded cure rates of 73% with the azoles vs. 80% with the allylamines. There were no detectable differences in efficacy between individual allylamines or individual azoles.

In general, topical antifungals are recognized as safe and well-tolerated, allowing for the switch from prescription to OTC status for terbinafine. Common adverse events reported with terbinafine include burning, stinging, peeling or other local reactions, which are commonly attributed to the vehicle or the condition itself; terbinafine does not appear to be any more likely to cause these adverse reactions than the other allylamine products on the UF.

Conclusion: The P&T Committee concluded that terbinafine 1% cream OTC has no clinically significant differences with respect to safety, efficacy, or tolerability, when compared to other allylamines included on the UF. The P&T Committee also concluded that it was unlikely that clinically significant differences exist between OTC terbinafine and the prescription allylamines for the treatment of common dermatologic infections.

2) *Relative Cost Effectiveness* – The P&T Committee evaluated the relative cost effectiveness of terbinafine 1% cream OTC in relation to efficacy, safety, tolerability, and clinical outcomes of the other allylamines in the topical antifungal class. Information considered by the P&T Committee included, but was not limited to, sources of information listed in 32 CFR 199.21(e)(2).

   Based on the information reported from the relative clinical effectiveness evaluation, there was evidence to suggest that terbinafine 1% cream OTC has similar efficacy, safety, tolerability, and clinical outcomes compared to the other allylamines in the topical antifungal class.

   The cost review for terbinafine 1% cream OTC compared the Federal Supply Schedule cost per 30 grams to the other allylamines, naftifine and butenafine.

   Conclusion: The results of the cost review showed that terbinafine 1% cream OTC is more cost effective than other allylamines in the topical antifungal class (butenafine and naftifine) across all three points of service.

3) *Clinical and Cost Effectiveness Conclusions* – The P&T Committee voted (14 for, 0 opposed, 1 abstained, 2 absent) to accept the clinical and cost effectiveness conclusions stated above.

   COMMITTEE ACTION – Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations, and other relevant factors, the P&T Committee, based upon its collective professional

judgment, voted (13 for, 0 opposed, 1 abstained, 3 absent) to recommend that terbinafine 1% cream OTC be classified as formulary on the UF for the OTC Demonstration Project.

4) *Medical Necessity (MN) Criteria* – Since terbinafine 1% cream OTC was not recommended for non-formulary status under the UF, establishment of MN criteria is not applicable.

5) *UF Implementation Period* – Since terbinafine 1% cream OTC was not recommended for non-formulary status under the UF, establishment of an implementation plan is not applicable.

6. DRUG CLASS REVIEW – ANTILIPIDEMIC AGENTS II (LIP-2s)

The P&T Committee evaluated the relative clinical effectiveness of the Antilipidemic Agents II (LIP-2) agents. This class is divided into three subclasses: fibric acid derivatives, omega-3 fatty acids, and bile acid sequestrants. Omega-3 fatty acid ("fish oil") products include the prescription product Omacor, along with a number of nutritional supplement products available OTC. Of these, only Omacor is eligible for inclusion on the UF.

The LIP-2 drug class accounted for $63 million in Military Health System (MHS) expenditures in FY 2006, ranking in the top 20 in terms of total expenditures. By comparison, the LIP-1 drug class reviewed in August 2006 (statins, ezetimibe, niacin, and combinations) accounted for $500 million in MHS expenditures and was ranked #1.

A. LIP-2s – Relative Clinical Effectiveness

The P&T Committee evaluated the relative clinical effectiveness of the LIP-2 agents currently marketed in the U.S. Information regarding the safety, effectiveness, and clinical outcomes of these drugs was considered. The clinical review included, but was not limited to, the requirements stated in the UF Rule, 32 CFR 199.21(e)(1). The P&T Committee was advised that there is a statutory presumption that pharmaceutical agents in a therapeutic class are clinically effective and should be included on the UF, unless the P&T Committee finds by a majority vote that a pharmaceutical agent does not have a significant, clinically meaningful therapeutic advantage in terms of safety, effectiveness, or clinical outcome over the other pharmaceutical agents included on the UF in that therapeutic class.

Table 1: Antilipidemic II Agents Available in the U.S.

Subclass	Generic Name	Brand Name
Fibric Acid Derivatives	Gemfibrozil	Lopid, generics
	Fenofibrate	
	Nanocrystallized	Tricor
	Non-micronized/micronized	Lofibra (generic to innovator Tricor)
	Micronized	Antara
	IDD-P (micronized)	Triglide
Omega-3 fatty acids	Omega-3 fatty acid	Omacor
Bile Acid Sequestrants	Cholestyramine/aspartame	Questran Light, Prevalite, generics
	Cholestyramine/sucrose	Questran, generics
	Colestipol	Colestid, generics
	Colesevelam	Welchol

IDD-P = Insoluble Drug Delivery - microParticle

1) Formulations

a) Fibric Acid Derivatives

i) Products

The fibric acid derivatives available commercially include gemfibrozil (Lopid, generics) and several formulations of fenofibrate. Fenofibrate is a prodrug that is metabolized to its active ingredient, fenofibric acid. The innovator fenofibrate product launched in 1998 under the trade name Tricor by Abbott Laboratories was very insoluble in water, thus was poorly absorbed and required administration with food. Drug particle size has been reduced in newer fenofibrate formulations to enhance absorption compared to the original fenofibrate product. As products are re-formulated, previous versions are typically removed from the market.

The most recent fenofibrate formulations are micronized fenofibrate (Antara), insoluble drug delivery microparticle (IDD-P) fenofibrate (Triglide), and nanocrystallized fenofibrate (Tricor). Antara, Triglide, and Tricor can be taken without regard to meals.

The innovator fenofibrate formulation has been discontinued by Abbott, along with a later version. The current Tricor product (nanocrystallized) is the third version on the market. Lofibra is a branded generic to the two earlier Tricor formulations, and is available in both a micronized and non-micronized version.

ii) FDA approval process

The newer fenofibrate formulations received FDA approval via a 505b(2) application. Under this process, newer products are approved by demonstrating bioequivalence to the original new drug application of the innovator fenofibrate 200 mg product. The newer formulations are marketed in varying dosage strengths lower than 200 mg. However, bioequivalence is similar between innovator fenofibrate 200 mg, IDD-P micronized fenofibrate (Triglide) 160 mg, nanocrystallized fenofibrate 145 mg, and micronized fenofibrate (Antara) 130 mg.

b) Omega-3 Fatty Acids

i) Products

Fish oil Supplements – The omega-3 fatty acids include eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA). Several formulations of omega-3 fatty acids (fish oils) are available as dietary supplements. Dietary products do not undergo the rigorous approval process required for prescription products.

Prescription omega-3 fatty acids (Omacor) – Omacor is a marine-derived omega-3 polyunsaturated fatty acid product that was approved by the FDA in 2004. It is the first and only prescription fish oil product available. Each 1-gram Omacor capsule contains 90% omega-3 acid esters,

consisting of 465 mg (46%) EPA, 375 mg (38%) DHA), 6% other omega-3 acid esters, and 10% omega-6 fatty acids.

ii) FDA indication

Fish Oil Supplements – The FDA allows a qualified health claim for dietary supplements and conventional foods containing EPA and DHA omega-3 fatty acids to reduce the risk of coronary heart disease (CHD).

Omacor – Omacor is currently approved only as an adjunct to diet in patients with very high triglyceride (TG) levels (>500 mg/dL).

iii) Off-label uses

Prevention of CHD – In Europe, fish oil supplements are approved by regulatory authorities for secondary prevention of CHD. The U.S. FDA has not approved use of the Omacor product for CHD prevention, as it considers the data incomplete. In February 2007, the manufacturer added wording to the labeling stating that Omacor has not been shown to prevent myocardial infarction (MI) or strokes. However, Omacor is likely to be used off-label for CHD prevention.

c) Bile Acid Sequestrants

i) Products – The bile acid sequestrants (BAS) have been marketed since the 1960s and are still utilized for lowering low density lipoprotein (LDL). The class consists of cholestyramine/sucrose (Questran, generics), cholestyramine/aspartame (Questran Light, generics), colestipol (Colestid, generics), and the newest agent, colesevelam (Welchol).

ii) Indications – The BAS are all indicated for use as either monotherapy or in combination with statins to reduce LDL.

iii) Pharmacokinetics – The BAS are not absorbed and are not hydrolyzed by digestive enzymes. The older agents preferably bind to dihydroxy bile acids over trihydroxy bile acids. Colesevelam binds to both dihydroxy and trihydroxy bile acids equally, thus removing both types of bile acids from the circulation. *In vitro* lab data suggests that colesevelam is 4 to 6 times more potent than the older BAS in regard to lower total cholesterol and LDL levels, possible due to enhanced binding of trihydroxy bile acids. However, this difference in *in vitro* binding has not translated into enhanced efficacy of colesevelam in clinical trials assessing lipid parameters.

2) Efficacy

a) Efficacy Measures

The primary efficacy measures used to assess efficacy of the LIP-2 agents are reduction in LDL, TG, and total cholesterol levels (TC), and increases in high-density lipoprotein (HDL). The fibric acid derivatives and omega-3 fatty acids primarily reduce elevated TG levels and raise HDL. The BAS primarily reduce LDL.

When available, clinical outcomes data (reduction of CHD risk, including MI, mortality (all-cause or CHD), need for revascularization, and stroke) were also evaluated to assess differences between agents.

b) Fibric Acid Derivatives

i) Lipoprotein efficacy

Package inserts – The majority of clinical trials evaluating lipid effects have compared gemfibrozil or fenofibrate (Tricor, Antara, Triglide, Lofibra) with placebo. Both fenofibrate and gemfibrozil reduce TG levels by 20 to 50% and increase HDL by 10 to 20%. Varying effects on LDL concentrations are seen, ranging from reductions to increases of 5 to 20%.

Head-to-head trial – One small comparative trial with the fibric acid derivatives is available. Micronized fenofibrate 200 mg (an earlier Tricor formulation) was compared to gemfibrozil in 21 patients with type IIa and IIb hyperlipidemia. After six weeks, similar reductions in triglycerides were seen between the two agents (54% with fenofibrate vs. 46.5% with gemfibrozil; not statistically significant). However, micronized fenofibrate resulted in greater reductions in LDL and TC than gemfibrozil. The differences in LDL effects were likely attributed to the fact that a gemfibrozil dose of 900 mg QD was used, rather than the FDA-approved 600 mg BID dosage.

ii) Clinical outcomes

Three placebo-controlled trials are available that assessed clinical outcomes for gemfibrozil (HHS, VA-HIT) and fenofibrate (FIELD). There are no published head-to-head trials available that assess clinical outcomes (e.g. all-cause mortality, CHD mortality, MI, etc).

- *Helsinki Heart Study 1987 (HHS)* – HHS was a double-blind, placebo-controlled study conducted in 4,000 Finnish men (average age 47 years) who did not have CHD (primary prevention trial). After five years, gemfibrozil 600 mg BID resulted in a significant reduction (34%) in nonfatal MI and CHD death, compared to placebo. There was no difference between gemfibrozil and placebo in all-cause mortality.
- *Veteran Affairs High density lipoprotein cholesterol Intervention Trial 2001 (VA-HIT)* – VA-HIT was a secondary prevention trial conducted in over 2,000 male VA patients who had a history of CHD (average age 64 years). After five years, compared to placebo, treatment with gemfibrozil 600 mg BID resulted in a significant reduction (22%) in the risk of nonfatal MI or CHD death. There was no difference in death due to any cause. Thirty percent of the study participants were diabetic, and when this subpopulation was analyzed, significant reductions in the composite of nonfatal MI, stroke and CHD death were seen.

- *Fenofibrate Intervention and Event Lowering in Diabetes 2005 (FIELD)* – The FIELD trial was a randomized double-blinded placebo-controlled trial which included 9,975 type 2 diabetic participants, 2,131 of whom had cardiovascular disease. Patients were treated with fenofibrate 200 mg QD or placebo for 5 years. Patients were not receiving statins at the start of the study, but could start antilipidemic therapy, including statins, during the trial.

  After five years, there was no statistically significant difference between fenofibrate and placebo in the primary composite endpoint of nonfatal MI and CHD death (5.9% vs. 5.2%, respectively, hazard ratio 0.89, 95% CI 0.75-1.05). However, statistically significant reductions in nonfatal MI (4% vs. 3%) and total cardiovascular events (14% vs. 13%) were seen with fenofibrate. Reductions in total cardiovascular events were primarily due to a significant reduction in the need for coronary revascularization (7% vs. 6%). The concomitant use of statins in 17% of the placebo group vs. only 8% of the fenofibrate group may have accounted for the modest effect of fenofibrate in reducing cardiovascular events.

  An unexpected finding was a 19% (p=0.22) increase in CHD death with fenofibrate compared to placebo, reflecting an increase in sudden deaths in the fenofibrate group.

iii) Efficacy conclusion

Clinically the fibric acid derivatives are useful in reducing elevated TG concentrations and raising HDL. There are no major clinical differences between gemfibrozil and fenofibrate in terms of changes in lipid parameters as shown in the HHS, VA-HIT and FIELD clinical trials; both drugs reduce TG by 20-50%, and increase HDL by 10-20%. Varying effects on LDL have been reported. One small head-to-head trial reported that fenofibrate resulted in greater reductions in TG and LDL than gemfibrozil; however, the gemfibrozil dose was lower than that recommended in the product labeling.

Two placebo-controlled trials with gemfibrozil have shown a benefit in reducing the risk of cardiovascular events in a primary prevention setting and the risk of nonfatal MI and CHD death in a secondary prevention setting. Mixed results were demonstrated with fenofibrate in a large outcomes trial in a primary/secondary prevention setting; fenofibrate did not result in a statistically significant benefit in reducing the composite of CHD death or nonfatal MI, but was associated with significant reductions in nonfatal MI and coronary revascularization.

b) Omega-3 fatty acids

i) Lipoprotein efficacy

Fish oil supplements: placebo-controlled trials – One meta-analysis of 36 crossover and 32 parallel studies of dietary and supplemental omega-3 fatty acids reported that a 3- to 4-gram daily dose resulted in a reduction of TG by

25-34%, and an increase in LDL by 4-11%, regardless of source or formulation.

Omacor: placebo-controlled trials – Ten prospective, randomized clinical trials have examined the effects of the marketed Omacor formulation on TG and LDL concentrations in patients with elevated TG levels. Overall, Omacor 4 grams daily resulted in a 20-45% reduction in TG levels when compared to placebo. The TG-lowering response appears to correlate with baseline TG levels (e.g. patients with higher baseline TG levels will generally have a greater TG-lowering response).

Increases in LDL ranging from 17 to 31% were reported in four of the ten studies. Increases in LDL also appeared to correlate with baseline TG levels. Concomitant use of a statin may blunt any increase in LDL associated with Omacor.

ii) Omacor vs. fish oil supplements – There are no head-to-head trials comparing the lipid effects of Omacor vs. nutritional omega-3 fatty acid supplements.

iii) Omacor vs. other lipid-lowering therapies – The TG-lowering effects of Omacor are slightly lower than those achieved with fibric acid derivatives or niacin. Omacor is associated with similar increases in HDL compared to fibric acid derivatives and niacin.

iv) Clinical outcomes

- *Fish oil supplements: systematic reviews/meta-analyses* – The effects of dietary or supplemental omega-3 fatty acids on cardiovascular disease outcomes have been evaluated in several meta-analyses and systematic reviews, with conflicting results reported. Some reports suggest a beneficial effect when omega-3 fatty acids are used for either primary or secondary cardiovascular disease prevention. In contrast, a 2004 Cochrane review of randomized controlled trials and cohort studies found no strong evidence that dietary or supplemental omega-3 fatty acids reduced total mortality, cardiovascular events, or cancer.
- *Fish oil supplements: placebo-controlled trial (GISSI-Prevenzione)* – In the Gruppo Italiano per lo Studio della Sopravvivenza nell'Infarcto miocardico (GISSI)-Prevenzione Trial, an omega-3 fatty acid with a different ratio of EPA and DHA than Omacor was evaluated. Fish oil supplementation was associated with a 15% reduction in the risk of the composite endpoint of death, nonfatal MI, and stroke in 11,324 survivors of a recent MI. There was a 20% reduction in all-cause mortality, which was driven by a 45% reduction in sudden death. There was no difference in nonfatal MI between the groups. Limitations to the study include the open label study design, a dropout rate nearing 30% by study completion, use of a fish oil supplement different than Omacor, and high dietary intake of fish (which in itself has cardiovascular benefits).

- *Omacor: placebo-controlled trial* – One placebo-controlled, double-blinded trial evaluated the effect of Omacor on cardiovascular outcomes. In this study, 300 patients with acute MI were randomly assigned to receive Omacor 4 grams daily or corn oil placebo for a median time period of 1.5 years. There was no statistically significant difference in the rate of cardiac events (cardiac death, resuscitation, recurrent MI, and unstable angina) between groups (28% with Omacor vs. 24% with placebo, hazard ratio 1.19, 95% CI 0.76-1.86). The lack of difference was attributed to the small size and short duration of the trial, as well as the inclusion of Norwegian patients whose diets already contained a high content of fish.
- *Omacor vs. fish oil supplements* – There are no head-to-head trials of Omacor versus fish oil supplements.
- *Omacor vs. other lipid-lowering therapies* – Niacin and gemfibrozil both have clinical trial evidence supporting long-term benefits on cardiovascular outcomes.

v) Efficacy conclusion: Randomized clinical trials showed a reduction in TG levels of 20-45% with Omacor 4 grams once daily. However, Omacor has also been associated with increases in LDL, which may offset beneficial reductions in TG. Concomitant use of a statin may blunt increases in LDL.

The GISSI-Prevenzione trial is the largest trial showing a benefit of omega-3 fatty acids on cardiovascular outcomes, but it assessed a different omega-3 fatty acid product and not Omacor. Its validity may also be limited by its open-label design, high dropout rate, and high dietary fish intake. A small, short-duration placebo-controlled trial specifically assessing the cardio-vascular outcomes of Omacor did not demonstrate a reduction in cardiac events.

The TG-lowering effect of Omacor is slightly less than that achieved with either fibric acid derivatives or niacin. In the National Cholesterol Education Panel (NCEP) guidelines, fibric acid derivatives or niacin are listed as first-line treatments for patients with TG >500 mg/dL; both have clinical outcomes data supporting a benefit in reducing the risk of cardiovascular events.

c) Bile Acid Sequestrants

i) Lipoprotein efficacy – There are only a few clinical trials available for the BAS, and most were conducted in the 1970s and early 1980s. No trials have compared the older agents, cholestyramine and colestipol, with colesevelam.

- *Cholestyramine* – The Lipid Research Clinics Coronary Primary Prevention Trial (LRC-CPPT) was a large placebo-controlled trial that compared cholestyramine 24 g QD to placebo in preventing coronary artery disease (CAD) in 3,806 men with primary hypercholesterolemia. Treatment with cholestyramine resulted in greater reductions in TC and

LDL than placebo (TC -17% with cholestyramine vs. -1% with placebo; LDL -26% with cholestyramine vs. -5% with placebo ($p<0.001$).

The National Heart, Lung, and Blood Institute (NHLBI) compared cholestyramine with placebo in 143 patients. Cholestyramine reduced LDL by 26% vs. 5% with placebo ($p<0.001$). There was no significant difference between cholestyramine and placebo in TG or HDL levels.

- *Colesevelam* – One double-blind study compared various doses of colesevelam to placebo for 24 weeks in 494 patients with primary hypercholesterolemia. LDL levels decreased by 18% at the highest dose; all colesevelam doses reduced LDL significantly versus placebo ($p<0.001$). There were small, non-clinically significant increases in HDL and TG.
- *Colestipol* – One large placebo-controlled trial with colestipol published in 1978 reported a 12% reduction in TC; LDL values were not reported.
- *Cholestyramine or colestipol vs. placebo* – In 1972, a study of 45 adults with hyperlipidemia examined the cholesterol lowering activity and safety of colestipol monotherapy or cholestyramine monotherapy versus placebo. After one year of therapy, colestipol and cholestyramine had a similar effect on TC (40% reduction).

ii) Combination therapy with a statin – The BAS are uncommonly used as monotherapy; they are more likely to be used as adjunctive therapy with a statin. Colestipol plus simvastatin (Zocor, generics) has produced LDL reductions of 45-50%. Colesevelam plus simvastatin has resulted in a 48% reduction in LDL.

iii) Clinical outcomes – The only BAS trial that evaluated clinical outcomes was the LRC-CPPT with cholestyramine. This trial reported a 19% reduction in the combined rate of CHD death plus nonfatal MI with cholestyramine vs. placebo (7% vs. 95, respectively; $p<0.05$).

iv) Efficacy conclusion – Treatment with a BAS reduces LDL by15-30%. Use of BAS as monotherapy has declined in popularity, since statins offer greater LDL reduction. Based on indirect comparison of placebo-controlled trials, cholestyramine, colestipol, and colesevelam have comparable efficacy in lowering LDL. There are no direct comparative trials. There is clinical evidence supporting the use of cholestyramine for reducing the risk of cardiovascular events; no such benefit has been documented with colestipol or colesevelam.

3) 3) Safety / Tolerability

a) Fibric Acid Derivatives

i) Myopathy with statin combination therapy

- *Background* – An increased risk of myositis and potentially fatal rhabdomyolysis has been reported with fibric acid derivatives, either as monotherapy or in combination with a statin (particularly cerivastatin); it

appears to be dose-related. This risk was first identified via spontaneous reports to the FDA Adverse Event Reporting System (AERS).

- *Gemfibrozil vs. fenofibrate* – Mechanistically, differences in glucuronidation pathways between gemfibrozil and fenofibrate are postulated to account for potential differences in the risk of developing myotoxicity. Gemfibrozil undergoes glucuronidation metabolism through the uridine diphosphate glucuronosyl transferase (UGT) 1A1 and 1A3 pathways, which results in competition with the statins. Fenofibrate is eliminated via UGT 1A9 and 2B7 pathways, which do not appear to interfere with statin glucuronidation.
- *FDA retrospective review* – A retrospective data analysis of the FDA AERS database found that half of the cases of statin-induced rhabdomyolysis identified were associated with concomitant medications affecting statin metabolism, and of these more than one third were associated with fibric acid derivatives, gemfibrozil in particular. Many of these reports involved cerivastatin, which has now been withdrawn from the market.

  Another study evaluating the FDA AERS database analyzed the reporting rate (not incidence rate) of myotoxicity between fenofibrate plus a statin vs. gemfibrozil plus a statin. Based on 606 adverse event reports compiled from 1998 to 2002, the reporting rate (rhabdomyolysis cases per million U.S. prescriptions) was 0.58 for fenofibrate and 8.6 with gemfibrozil. This study excluded cerivastatin, which has now been withdrawn from the market. Limitations include varying definitions of myotoxicity, lack of verification of data, and the use of spontaneous reporting rates, which are subject to reporting bias and do not establish a causal relationship.
- *Fenofibrate/statin combination trial* – In 2005, one randomized, double-blinded 18-week trial (n=600) evaluated safety of monotherapy with low-dose simvastatin (20 mg) versus combination therapy with a standard dose of fenofibrate plus simvastatin 20 mg. The incidence of myalgia in the combination group was 2.2% vs. 2.4% with simvastatin. There were no reports of rhabdomyolysis.
- *Clinical practice guidelines* – Professional organizations have not favored one fibric acid derivative over the other with respect to safety of use in combination with statins. The most recent joint guidelines (2003) from the American College of Cardiology, the American Heart Association, and the NHLBI conclude that there is a risk with all fibric acid derivative/statin combinations, not just gemfibrozil plus statins.

ii) Minor adverse effects

- *Lab abnormalities* – Both gemfibrozil and fenofibrate have been associated with abnormal liver function tests when administered as monotherapy. Increases in serum creatinine ranging from 8 to 18% have

been reported with fenofibrate in patients with normal or impaired renal function. Product labeling advises monitoring of serum creatinine during therapy with either fenofibrate or gemfibrozil.

- *Gemfibrozil vs. fenofibrate: minor adverse effects* – Gastrointestinal (GI) complaints (e.g., nausea, vomiting, and diarrhea) are most common for both fenofibrate and gemfibrozil. Although they occur in fewer than 5% of patients taking fibric acid derivatives, they appear to occur more often with gemfibrozil than with fenofibrate, based on pooled data from product labeling. The head-to-head efficacy trial mentioned earlier (conducted in 21 patients) did not report adverse events.
- *Fenofibrate formulations: minor adverse effects* – There are no head-to-head trials assessing differences in adverse effects among the newer fenofibrate formulations. Differences in fenofibrate formulations are primarily related to decreases in particle size designed to address bioavailability issues, allowing the most recent products (Tricor, Antara, and Triglide) to offer once daily dosing and be taken without regard to meals. These differences do not appear to equate to differences in GI adverse effects, although comparative data are not available.

iii) Special populations – None of the fibric acid derivatives are FDA-approved for use in pediatric patients. All are rated Pregnancy Category C. Dosage adjustments for both gemfibrozil and fenofibrate are required in patients with mild renal impairment.

iv) Drug interactions –There appear to be no major clinical differences between the products with respect to drug interactions with products other than statins, which were discussed previously.

v) Safety conclusion – There are no head-to-head trials supporting a lower risk of myotoxicity with gemfibrozil than with fenofibrate, either alone or in combination with a statin, and professional organizations have not favored one fibric acid derivative over the other. The most recent joint guidelines (2003) from the American College of Cardiology, the American Heart Association, and the NHLBI conclude that there is a risk with all fibric acid derivative/statin combinations, not just gemfibrozil plus statins.

GI complaints (e.g., nausea, vomiting, and diarrhea) are most common for both fenofibrate and gemfibrozil. Although they occur in fewer than 5% of patients taking fibric acid derivatives, they appear to occur more often with gemfibrozil than with fenofibrate, based on pooled data from product labeling. There are no comparative data. There are no clinically significant differences between gemfibrozil and fenofibrate with regard to use in special populations or drug interaction potential.

b) Omacor

i) Minor adverse events – Omacor appears to be safe and well tolerated, with GI disturbances reported most commonly. Patients frequently complain of fishy-smelling breath and taste perversion, which may limit compliance.

ii) Special populations – Safety of Omacor has not been evaluated in pediatric patients or pregnant patients. No dosage adjustments are required in renal or hepatic impairment.

iii) Drug-drug interactions – Patients receiving Omacor and anticoagulants require periodic monitoring, due to the potential risk of increased bleeding. Clinically significant drug interactions due to inhibition of CYP450 metabolism are not expected with Omacor.

c) Bile Acid Sequestrants

i) Systemic adverse events – The BAS are not absorbed, thus are associated with a low incidence of systemic effects. Non-GI effects (such as angina and tachycardia, or rash) are rare.

ii) GI adverse events – Constipation is the most common minor adverse effect with all the BAS, occurring with an incidence of greater than 10%. In the LRC-CPPT trial, the incidence of constipation with cholestyramine was 39% vs. 10% with placebo; however, GI distress from cholestyramine appeared to decrease with time. Constipation appears to occur less frequently with colesevelam than with other BAS, based on pooled data in product labeling. Rare reports of GI obstruction, including two deaths, have been reported in pediatric patients receiving cholestyramine.

Chronic use of BAS can cause bleeding due to hypoprothrombinemia secondary to malabsorption of vitamin K.

iii) Drug-drug interactions – Drug interactions with BAS are primarily due to effects on absorption of concomitant oral medications.

iii) Special populations

Pediatrics – Cholestyramine is the only BAS that is FDA-indicated to treat hypercholesterolemia in the pediatric population.

Pregnancy – Cholestyramine and colestipol have a Pregnancy Category C rating; colesevelam has a Category B rating. Because statins are rated Pregnancy Category X, NCEP guidelines state that BAS are recommended for women with elevated cholesterol who are considering pregnancy.

4) Other Factors

a) Fibric Acid Derivatives – Gemfibrozil is given twice daily before meals, while the newer formulations of fenofibrate ((Tricor, Triglide, Antara) may be given once daily without regard to meals.

b) Omega-3 Fatty Acids – Since Omacor has undergone the new drug approval process, the ratio and amount of DHA and EPA contained in each capsule and the amount of other ingredients is known. The FDA has more authority to oversee manufacturing of Omacor than fish oil supplements. Fish oil supplement manufacturers are not required to list ingredients other than omega-3 fatty acids (e.g., omega-6 fatty acids, cholesterol) in their label. The

Omacor formulation requires four capsules daily; higher capsule burdens are necessary with some fish oil supplements.

c) Bile Acid Sequestrants – Cholestyramine is only available in a powder form, which some patients find unpalatable. Cholestyramine and colestipol are available as powders or granules for oral suspension, with colestipol also available in tablet form. Both colestipol and colesevelam require large daily tablet burdens (up to sixteen tablets per day for colestipol and seven for colesevelam).

5) Place in Therapy

a) Fibric Acid Derivatives – Fibric acid derivatives have been used clinically since the 1970s and are effective at lowering TG levels and raising HDL. They are widely used as adjunctive treatment with statins, which primarily reduce LDL.

b) Prescription Omega-3 Fatty Acids (Omacor) – Omacor provides an alternative for patients with elevated TG who are not candidates for niacin or fibric acid derivatives. The American Heart Association (AHA) recommends niacin as first-line for elevated TG. The AHA recommends consumption of a variety of fish as primary prevention, with omega-3 fatty acids potentially considered for secondary prevention. NCEP guidelines recommend either fibric acid derivatives or niacin as first line for elevated TG, along with a high dietary intake of fatty fish or omega-3-containing vegetable oils.

c) Bile Acid Sequestrants – NCEP guidelines recommend BAS for LDL-lowering in patients with moderately elevated LDL; women who are considering pregnancy and have elevated LDL; and patients who need only modest reductions in their LDL to reach their target goal.

6) *Overall Clinical Effectiveness Conclusion* – The P&T Committee concluded that:

a) Fibric Acid Derivatives

i) Both gemfibrozil and fenofibrate reduce TG by 20-50% and raise high density lipoprotein (HDL) by 10-20%. There is insufficient evidence to conclude that gemfibrozil and fenofibrate differ in their ability to reduce TG and raise HDL.

ii) Two placebo-controlled trials with gemfibrozil have shown a benefit in reduction of cardiovascular events in a primary prevention setting and a reduction in nonfatal MI and CHD death in a secondary prevention setting. Mixed results were demonstrated with fenofibrate in a large outcomes trial in a primary/secondary prevention setting; fenofibrate did not result in a statistically significant benefit in reducing the composite of CHD death or nonfatal MI, but was associated with significant reductions in nonfatal MI (p=0.01) and coronary revascularization (p=0.035).

iii) Although GI adverse effects occurred in fewer than 5% of patients taking fibric acid derivatives, they appeared to occur more frequently in patients taking gemfibrozil than those taking fenofibrate, based on pooled data

from product labeling. Gemfibrozil must be taken twice daily prior to meals.

iv) Monotherapy with either fibric acid derivatives or statins has been associated with an increased risk of myalgia, myositis, and rhabdomyolysis. This risk appears to be increased with gemfibrozil/statin combination therapy, based on spontaneous adverse event reporting data from the FDA. These data showed a higher reporting rate of rhabdomyolysis with a statin plus gemfibrozil (8.6) compared to a statin plus fenofibrate (0.58), based on the number of spontaneous case reports per 1 million U.S. prescriptions from 1998 to 2002. This study excluded cerivastatin, which has now been withdrawn from the market. Limitations include varying definitions of myotoxicity, lack of verification of data, and the use of spontaneous reporting rates, which are subject to reporting bias and do not establish a causal relationship. It is unclear whether combination therapy with fenofibrate and a statin increases the risk of myotoxicity more than either agent given alone. One trial comparing statin monotherapy vs. combination therapy with fenofibrate plus a statin reported similar rates of myalgia.

v) Pharmacokinetic differences in glucuronidation pathways between gemfibrozil and fenofibrate are postulated to account for potential differences in the risk of developing myotoxicity when used in combination with a statin. However, there are no head-to-head trials supporting a lower risk of myotoxicity with gemfibrozil than with fenofibrate, either alone or in combination with a statin, and professional organizations have not favored one fibric acid derivative over the other. The most recent joint guidelines (2003) from the American College of Cardiology, the American Heart Association, and the NHLBI conclude that there is a risk with all fibric acid derivative/statin combinations, not just gemfibrozil plus statins.

vi) Fenofibrate formulations include nanocrystallized fenofibrate (Tricor), micronized fenofibrate (Antara), insoluble drug delivery microparticle (IDD-P) fenofibrate (Triglide) and generic formulations of non-micronized and micronized fenofibrate (Lofibra). These newer formulations, regardless of dosage strength or particle size, are bioequivalent to 200 mg of the original fenofibrate formulation. Changes in particle size are designed to address bioavailability issues, allowing the most recent products (Tricor, Antara and Triglide) to offer once daily dosing and be taken without regard to meals. There is insufficient evidence to conclude that newer formulations offer improved efficacy, safety, or tolerability compared to each other or to older formulations.

b) Omega-3 Fatty Acids

i) Omacor is the only prescription omega-3 fatty acid product approved by the FDA. FDA oversight of the manufacturing process for Omacor offers

increased assurance of its omega-3 fatty acid content and purity, in contrast to some fish oil supplements.

ii) Overall, Omacor decreases TG by 20-45%. However, Omacor has also been associated with increases in LDL, which may offset beneficial reductions in TG.

iii) The TG-lowering effects of Omacor are slightly lower than those achieved with fibric acid derivatives or niacin. Omacor is associated with similar increases in HDL compared to fibric acid derivatives and niacin. Niacin and gemfibrozil both have clinical trial evidence supporting long-term benefits on cardiovascular outcomes.

iv) The omega-3 fatty acid formulation found in Omacor does not have outcomes studies that demonstrate beneficial cardiovascular effects (e.g., reductions in cardiovascular death, MI or stroke).

c) Bile Acid Sequestrants

i) The BAS agents reduce LDL by 15-30%. This subclass has largely been replaced by the statins, which decrease LDL by 18% to 55%. There is insufficient evidence to conclude that BAS differ in their ability to lower LDL. Cholestyramine is the only BAS to show beneficial effects on cardiovascular outcomes.

ii) Colesevelam has no major efficacy advantages compared to cholestyramine or colestipol, despite manufacturer claims of enhanced bile acid binding capacity. It has a more favorable pregnancy category rating than the older products (B vs. C) and may cause less constipation, which may be clinically relevant in patients with a previous history of GI obstruction.

iii) Issues with palatability of powder formulations and/or large daily tablet burdens are a concern with the class as a whole and may affect compliance.

iv) The BAS agents have a high degree of therapeutic interchangeability.

Overall Clinical Effectiveness Conclusion – Based on clinical issues alone, there are no compelling reasons to classify any of the LIP-2 agents as non-formulary under the UF.

COMMITTEE ACTION: The P&T Committee voted (15 for, 0 opposed, 0 abstained, 2 absent) to accept the clinical effectiveness conclusions above.

B. B. LIP-2s – Relative Cost Effectiveness

In considering the relative cost-effectiveness of pharmaceutical agents in this class, the P&T Committee evaluated the costs of the agents in relation to the efficacy, safety, tolerability, and clinical outcomes of the other agents in the class. Information considered by the P&T Committee included but was not limited to sources of information listed in 32 CFR 199.21(e)(2).

The relative clinical effectiveness evaluation concluded that there was insufficient evidence to suggest that the agents within the fibric acid derivative and BAS subclasses differed in regards to efficacy, safety, tolerability, or clinical outcomes data in the treatment of hypertriglyceridemia and hyperlipidemia, respectively. As a result, cost minimization analyses (CMAs) were performed to compare the relative cost effectiveness of the agents within the fibric acid derivative and BAS subclasses. Since Omacor is the only prescription omega-3 fatty acid product, a cost effectiveness analysis (CEA) was conducted to compare it to other agents used in the treatment of hypertriglyceridemia.

Results from the fibric acid derivative CMA revealed: 1) gemfibrozil was the most cost-effective fibric acid derivative, and 2) IDD-P fenofibrate (Triglide) was by far the most cost effective fenofibrate. Among the bile acid sequestrants, the CMA showed that colesevelam was not cost-effective in the treatment of hyperlipidemia when compared to other available agents. The results for the prescription omega-3 fatty acids CEA showed that Omacor was not cost effective in the treatment of hypertriglyceridemia when compared to gemfibrozil, fenofibrate, and niacin. At this time, there is insufficient evidence to support a clinical benefit for omega-3 fatty acids in prevention of CHD. For this reason, the cost effectiveness of Omacor was not evaluated for this consequence or clinical outcome.

Based on the results of the clinical review and the pharmacoeconomic evaluations, a budget impact analysis (BIA) of various UF scenarios for the LIP-2s was conducted. The goal of the BIA was to aid the Committee in determining which group of LIP-2s best met the majority of the clinical needs of the DoD population at the lowest expected cost to the MHS.

Cost Effectiveness Conclusion – The DoD P&T Committee accepted the conclusions from the cost effectiveness analyses stated above. In addition, the Committee concluded that the UF scenario that maintained fenofibrate (Lofibra), IDD-P fenofibrate (Triglide), cholestyramine/aspartame, cholestyramine/sucrose, colestipol, and gemfibrozil on the UF was the most cost effective UF scenario.

COMMITTEE ACTION: The P&T Committee voted (15 for, 0 opposed, 0 abstained, 2 absent) to accept the relative CEA of the LIP-2 class.

C. LIP-2s – UF Recommendations

COMMITTEE ACTION: Taking into consideration the conclusions from the relative clinical effectiveness and the relative cost effectiveness determinations for the LIP-2s, and other relevant factors, the P&T Committee recommended (13 for, 1 opposed, 1 abstained, 2 absent) that: 1) fenofibrate (Lofibra, generics), IDD-P fenofibrate (Triglide), cholestyramine/ aspartame, cholestyramine/sucrose, colestipol, and gemfibrozil be maintained as formulary on the UF; 2) micronized fenofibrate (Antara), nanocrystallized fenofibrate, colesevelam, and prescription omega-3 fatty acids (Omacor) be classified as non-formulary under the UF; and 3) the normal brand formulary cost-share of $9.00 for IDD-P fenofibrate (Triglide) be lowered to the generic formulary cost-share of $3.00.

The authority for the last recommendation is codified in 32 CFR 199.21(j)(3), which states that "when a blanket purchase agreement, incentive price agreement, Government contract, or other circumstances results in a brand pharmaceutical agent being the most cost effective agent for purchase by the Government, the P&T Committee may also designate that the drug be cost-shared at the generic rate." The objective is to maximize use of IDD-P fenofibrate (Triglide) in the retail network and mail order, given its significantly lower cost relative to other fenofibrate products. Lowering the cost-share for brand name IDD-P fenofibrate (Triglide) will provide a greater incentive for beneficiaries to use the most cost effective fenofibrate formulation in the purchased care arena

D. LIP-2s – MN Criteria

Based on the clinical evaluation and the conditions for establishing MN for a non-formulary medication provided for in the UF rule, the P&T Committee recommended the following general MN criteria for micronized fenofibrate (Antara), nanocrystallized fenofibrate, colesevelam, and omega-3 fatty acids (Omacor):

1) The use of formulary alternatives is contraindicated.
2) The patient has experienced or is likely to experience significant adverse effects from formulary alternatives.
3) Formulary alternatives have resulted in therapeutic failure.

The P&T Committee noted that some circumstances under which criterion #2 might be considered to apply may be 1) Omacor for patients who cannot take statins or fibric acid derivatives due to a history of myopathy and who cannot tolerate niacin, or 2) colesevelam for patients with a history of GI obstruction or pregnant patients who require treatment with a bile acid sequestrant.

COMMITTEE ACTION: The P&T Committee voted (13 for, 1 opposed, 1 abstained, 2 absent) to approve the MN criteria outlined above.

E. LIP-2s – UF Implementation Period

Given the relatively low number of beneficiaries are affected (approximately 83,612 patients (65%) of approximately 127,901 beneficiaries at all three points of service), the P&T Committee recommended an effective date of the first Wednesday following a 90-day implementation period. The implementation period will begin immediately following approval by the Director, TMA.

MTFs will not be allowed to have micronized fenofibrate (Antara), nanocrystallized fenofibrate, colesevelam, or prescription omega-3 fatty acids (Omacor) on their local formularies. MTFs will be able to fill non-formulary requests for these agents only if both of the following conditions are met: 1) the prescription must be written by a MTF provider, and 2) MN is established. MTFs may (but are not required to) fill a prescription for a non-formulary LIP-2 agent written by a non-MTF provider to whom the patient was referred, as long as MN has been established.

COMMITTEE ACTION: The P&T Committee recommended (14 for, 0 opposed, 1 abstained, 2 absent) an effective date of the first Wednesday following a 90-day

implementation period. The implementation period will begin immediately following the approval by the Director, TMA.

F. LIP-2s – BCF Review and Recommendation

Based on the results of the clinical and economic evaluations presented, the P&T Committee voted (14 for, 0 opposed, 1 abstained, 2 absent) to recommend that gemfibrozil and IDD-P fenofibrate (Triglide) be designated as the BCF selections in this class.

7. DRUG CLASS REVIEW – 5-ALPHA REDUCTASE INHIBITORS (5-ARIs)

The P&T Committee evaluated the relative clinical effectiveness of the 5-alpha reductase inhibitor agents (5-ARIs) available in the U.S. The 5-ARI drug class includes finasteride (Proscar, generics) and dutasteride (Avodart). These two agents have been marketed for a number of years; finasteride is available generically. The class review did not include the lower dosage (1 mg) strength of finasteride, which is marketed for alopecia (hair loss) under the brand name Propecia, since this indication is not covered by TRICARE.

The 5-ARI drug class accounted for $31.2 million in the MHS expenditures for the period October 2005 to September 2006 and is ranked #50 in terms of total expenditures during that time period. More than 281,000 prescriptions for 5-ARIs were filled in the MHS during a one-year period (January 2006 to December 2006). Of these, 59% were for finasteride and 41% were for dutasteride.

Pharmacologically, the 5-ARIs reduce prostate volume by inhibiting the conversion of testosterone to dihydrotestosterone (DHT). Finasteride selectively inhibits type I 5-alpha receptors, while dutasteride inhibits both type I and type II receptors; the clinical significance of this difference is unknown. 5-ARIs are used for the treatment of benign prostatic hyperplasia (BPH) in men with an enlarged prostate. Their effect on lower urinary tract symptoms (LUTS) associated with BPH (e.g., urinary frequency, urgency, nocturia, decreased / intermittent force of stream, and the sensation of incomplete bladder emptying) is related to relief of urethral obstruction and may take several months of treatment to become clinically evident. BPH to the point of prostatic obstruction can cause acute urinary retention (AUR), which is considered a medical emergency.

Standard treatments for BPH include watchful waiting (in men with mild symptomatic BPH); alpha blockers (which rapidly relieve symptoms by relaxing prostate and bladder smooth muscle but do not affect prostate volume); 5-ARIs (reduce prostate volume); combination alpha blocker/5-ARI treatment (in men with moderate-to-severe symptomatic BPH); and surgery (in men with severe symptomatic BPH).

A. 5-ARIs – Relative Clinical Effectiveness

The P&T Committee evaluated the relative clinical effectiveness of the 5-ARI agents currently marketed in the U.S. Information regarding the safety, effectiveness, and clinical outcomes of these drugs was considered. The clinical review included, but was not limited to, the requirements stated in the UF Rule, 32 CFR 199.21(e)(1). The P&T Committee was advised that there is a statutory presumption that pharmaceutical agents in a therapeutic class are clinically effective and should be included on the UF, unless the P&T Committee finds by a majority vote that a pharmaceutical agent does

not have a significant, clinically meaningful therapeutic advantage in terms of safety, effectiveness, or clinical outcome over the other pharmaceutical agents included on the UF in that therapeutic class.

1) FDA-approved indications

   Both finasteride and dutasteride are indicated for the treatment of symptomatic BPH in men with an enlarged prostate to improve symptoms, reduce the risk of AUR, and reduce the risk of the need for BPH-related surgery. Finasteride is approved for combination therapy with the alpha blocker doxazosin to reduce the risk of symptomatic progression of BPH; labeling for dutasteride does not include an indication for combination therapy. Both are dosed once daily without regard to meals.

2) Efficacy Measures

   The primary outcome measures used to assess efficacy of the 5-ARIs are changes in symptom scores (AUA-SI or IPSS), urinary flow rate (Qmax), reductions in total prostate volume (TPV), and decreased risk of AUR or BPH-related surgery. In trials, a decrease in symptom score of three or more points is generally considered clinically significant; although men rate themselves as slightly improved with a decrease of one to two points. A change in the urinary flow rate of 2 to 3 mL/sec is considered clinically significant.

3) Efficacy

   a) *Long term placebo-controlled trials* – The most extensive data supporting long term efficacy and safety of the 5-ARIs are from two large randomized, double-blind, placebo-controlled trials. The four-year Proscar Long-Term Efficacy and Safety Study (PLESS) [McConnell et al, 1998] showed a significant reduction in symptom scores, Qmax, TPV, risk of AUR, and risk of BPH-related surgery with finasteride, compared to placebo. Data for dutasteride come from pooled analyses of three identical parallel-group trials (ARIA 3001, 3002, 3003) [Roehrborn et al, 2002]. All three trials had a two-year double-blinded phase comparing dutasteride to placebo, followed by a two-year open-label extension phase during which all patients were treated with dutasteride. At the end of the two-year double-blind phase, dutasteride significantly reduced symptom scores, Qmax, TPV, risk of AUR, and risk of BPH-related surgery with finasteride, compared to placebo.

      Reductions in the risk of AUR and BPH-related surgery appeared similar. The calculated risk reduction after two years with finasteride (PLESS) was a 57% reduction in AUR (95% CI 40-69%) and a 58% reduction in BPH-related surgery 58% (95% CI 41-65%), compared with placebo. For dutasteride, the risk reduction after two years (ARIA pooled data) was 57% for AUR (95% CI 38-71%) and 48% for BPH-related surgery (95% CI 26-63%), compared with placebo.

   b) *Systematic reviews and meta-analysis* – Two systematic reviews [Clifford et al, 2000; Edwards et al, 2002] and one meta-analysis [AUA Guideline, 2003] concluded that finasteride offers consistent improvement in terms of symptom

relief, urinary flow rate, and decreased risk of AUR and the need for prostatic surgery, compared to placebo. No systematic reviews or meta-analyses are available for dutasteride.

Head-to-head trials – The only fully published head-to-head trial [Clark et al, 2004] compared effects of finasteride and dutasteride on DHT, testosterone, and leutinizing hormone (LH) levels. This 24-week, Phase II, double-blind, placebo-controlled, dose-ranging trial randomized 399 men with BPH to dutasteride (0.01, 0.05, 0.5, 2.5, or 5.0 mg), 5 mg finasteride, or placebo. The mean percent decrease in DHT with dutasteride was more profound and less variable than with finasteride [dutasteride 0.5 mg (the labeled dose) 94.7 ± 3.3% vs. finasteride 5 mg 70.8 ± 18.3%]. Mean testosterone levels increased but remained in the normal range for all treatment groups. Whether or not differences between finasteride and dutasteride with respect to DHT suppression result in a clinically significant difference in patient outcomes has yet to be determined. Limitations of this trial include its short duration relative to the typical onset of benefits from 5-ARIs and its small sample size, especially given that only one of the dutasteride arms was at the labeled dose (0.5mg).

Unpublished summary data from a second head-to-head trial, the Enlarged Prostate International Comparator Study (EPICS), were furnished by the manufacturer of dutasteride [data on file, GlaxoSmithKline]. EPICS compared dutasteride 0.5 mg and finasteride 5 mg in men with BPH. Following a 4-week placebo run-in period, 1630 men were randomized to dutasteride (n=813) or finasteride (n=817) for twelve months. After one year similar improvements from baseline were seen with dutasteride vs. finasteride, respectively, with respect to changes in symptom scores (-5.8 vs.- 5.5), reductions in TPV (-26.3% vs. -26.7%) and Qmax (2.0 vs. 1.7 mL/sec). No statistically significant differences in outcome measures between treatment groups were reported.

c) *Combination therapy trials* – Three short-term combination trials (finasteride plus an alpha blocker) demonstrated no additional benefit compared to alpha blockers alone. However, the large, long-term Medical Therapy of Prostatic Symptoms (MTOPS) trial demonstrated improvements in LUTS and a greater reduction in overall disease progression (including reduced risk of AUR and need for BPH-related surgery) with combination therapy (finasteride plus doxazosin) versus monotherapy with either agent. The AUA meta-analysis of finasteride trials reported improved AUA-SI scores and Qmax with combination therapy and supported its use in men with LUTS and demonstrable prostate enlargement. There are no published long-term combination trials with dutasteride; therefore, there is insufficient evidence to compare finasteride to dutasteride when used in combination with an alpha blocker.

d) *Prostate cancer* – There is limited evidence concerning the potential use of 5-ARIs for prostate cancer prevention. The only large, long-term trial [Thompson et al, 2003] reported a 24.8% reduction in the prevalence of

prostate cancer in patients receiving finasteride vs. placebo; however, a higher percentage of high-grade prostate cancer tumors was reported with finasteride, compared to placebo. It is not known whether or not dutasteride produces the same effect.

e) Efficacy conclusion – There is insufficient evidence to conclude that there are significant differences in efficacy between finasteride and dutasteride. Indirect comparisons from long-term efficacy trials suggest similar decreases in total prostate volume, increases in urinary flow rate, improvement in symptoms, and similar reductions in the risk of AUR and BPH-related surgery. Summary results from an unpublished head-to-head trial (the Enlarged Prostate International Comparator Study – EPICS) showed similar improvements in symptom scores, TPV, and Qmax; no statistically significant differences in outcome measures were reported. There is insufficient evidence to compare the two agents for use in combination with alpha blockers. More data are available with finasteride than with dutasteride, including a long-term trial with finasteride and doxazosin (the Medical Therapy of Prostatic Symptoms trial – MTOPS); there are no published long-term combination trials with dutasteride. The clinical significance of more profound suppression of DHT with dutasteride than with finasteride is unknown. The overall effect of 5-ARIs on prostate cancer prevention is unclear.

4) Safety and Tolerability

a) Serious adverse events – There have been no notable reports of serious adverse events with either agent.

b) Overall adverse events – The most common adverse effects are related to sexual dysfunction. Similar incidences of sexual adverse events and gynecomastia have been reported with finasteride and dutasteride. In general, clinical trials report rates of decreased libido of 2 to10%, erectile dysfunction 3 to16%, ejaculatory disorders 0 to 8%, and gynecomastia 1 to 2%. The incidence of sexual dysfunction is generally higher during the first six to twelve months of treatment and diminishes with chronic dosing.

c) Withdrawals due to adverse events during clinical trials – With the exception of gynecomastia, adverse effects are generally not severe enough to discontinue use of 5-ARIs. There do not appear to be major differences between the two agents with respect to withdrawal rates due to adverse events. Reported withdrawal rates in clinical trials of finasteride and dutasteride were low overall, similar in the first year of therapy, and decreased further for both agents during continued treatment.

d) Drug interactions – No major comparative disadvantage was noted for either agent based on its potential for drug-drug interactions. Both are metabolized via the cytochrome P450 (CYP) 3A4 enzyme system and should be used cautiously in patients taking potent CYP 3A4 inhibitors.

e) Special populations – There are no major differences between finasteride and dutasteride with regard to use in special populations; both are pregnancy category X, contraindicated in children and women, and carry warnings regarding exposure to 5-ARIs of women who are pregnant or may become pregnant, due to the potential risk of transdermal absorption and fetal exposure (feminization of male fetuses is an expected consequence of the inhibition of the conversion of testosterone to DHT by 5-ARIs). Men taking a 5-ARI should defer blood donation for six months from discontinuation of therapy to avoid possible administration of the drug to a pregnant female transfusion recipient. Neither finasteride nor dutasteride requires dosing adjustments or has special dosing requirements, although caution is advised in hepatic dysfunction.

f) Other factors – 5-ARIs as a class are associated with a decrease in prostate specific antigen (PSA) concentrations of about 50% after six months of treatment. Neither drug appears to interfere with detection of prostate cancer when PSA values used for prostate cancer screening are appropriately adjusted (they should be doubled in men who have received 5-ARI therapy for at least six months).

g) Safety and tolerability conclusion – There appear to be few differences in the incidence of adverse effects with finasteride or dutasteride, based on placebo-controlled trials and limited comparative data. Both agents are well tolerated; with the most common adverse effects related to sexual dysfunction and diminishing with chronic dosing. Reported withdrawal rates due to adverse effects are low overall in clinical trials of finasteride and dutasteride, similar during the first year of therapy, and decrease further with both agents during continued treatment. The two agents appear similar with regard to potential drug interactions and use in special populations (both are contraindicated in women and children and carry special warnings against exposure of women who are or may become pregnant). Neither agent appears to interfere with the prostate cancer detection.

5) Therapeutic Interchangeability

Finasteride and dutasteride appear similar in terms of efficacy, safety, and tolerability, and are used in the same patient population. Neither drug offers a unique benefit, nor is it likely that a patient who did not have an adequate response with one 5-ARI would have a better response with the other. Either finasteride or dutasteride could be expected to meet the needs of the majority of DoD BPH patients.

6) 5-ARIs – Overall Clinical Effectiveness Conclusion

The P&T Committee concluded that:

a) There is insufficient evidence to conclude that there are significant differences in efficacy between finasteride and dutasteride. Indirect comparisons from long-term efficacy trials suggest similar decreases in total prostate volume,

increases in urinary flow rate, improvement in symptoms, and similar reductions in the risk of AUR and BPH-related surgery.

b) The only fully published head-to-head trial suggests that dutasteride therapy reduces serum DHT levels by 95%, compared to 71% with finasteride. The clinical significance of this finding has yet to be determined. This 24-week trial contributes no useful comparative data concerning long-term efficacy. A large but as yet unpublished head-to-head trial (EPICS) reported no differences in efficacy outcomes with finasteride vs. dutasteride after one year of treatment.

c) There is insufficient evidence to compare the two agents when used in combination with alpha blockers. More data are available with finasteride than with dutasteride, including a long-term trial with finasteride and doxazosin (MTOPS); there are no published long-term combination trials with dutasteride.

d) The overall effect of 5-ARIs on prostate cancer prevention is unclear.

e) There appear to be few differences in the incidence of adverse effects with finasteride or dutasteride, based on placebo-controlled trials and limited comparative data. Both agents are well tolerated. The most common adverse effects are related to sexual dysfunction; they diminish with chronic dosing.

f) Reported withdrawal rates due to adverse effects are low in clinical trials of finasteride and dutasteride, similar during the first year of therapy, and decrease further with both agents during continued treatment.

g) There are no major differences between finasteride and dutasteride with regard to use in special populations or drug interactions.

h) Neither agent appears to interfere with prostate cancer detection.

i) Finasteride and dutasteride appear to have a high degree of therapeutic interchangeability; either could be expected to meet the needs of the majority of DoD BPH patients.

COMMITTEE ACTION: The P&T Committee voted (15 for, 0 opposed, 0 abstained, 2 absent) to accept the clinical effectiveness conclusions stated above.

B. 5-ARIs – Relative Cost Effectiveness

The P&T Committee evaluated the relative cost-effectiveness of the 5-ARIs in relation to efficacy, safety, tolerability, and clinical outcomes of the other agents in the class. Information considered by the P&T Committee included, but was not limited to, sources of information listed in 32 CFR 199.21(e)(2).

The relative clinical effectiveness evaluation concluded that there was insufficient evidence to suggest that the 5-ARI medications differed in regards to efficacy, safety, tolerability, or clinical outcomes data in the treatment of BPH. As a result, several CMAs were performed to compare the relative cost effectiveness of the 5-ARIs by condition set. The CMAs compared the weighted average cost per day of treatment

for each drug product across all three points of service. In addition, a CEA was conducted evaluating the cost per BPH surgery avoided for each of the 5-ARIs.

Results from the CMAs showed that finasteride was the most cost effective agent with a lower cost per day of treatment than dutasteride across all conditions sets evaluated. In addition, finasteride was the preferred choice in the CEA with a lower expected cost per BPH surgery averted than dutasteride.

Based on the results of the clinical review and the pharmacoeconomic evaluations, a BIA of various formulary scenarios was conducted to estimate the influence of other factors associated with a UF decision (i.e., market share migration, switch costs, non-formulary cost-shares). The goal of the BIA was to aid the Committee in determining which group of 5-ARIs best met the majority of the clinical needs of the DoD population at the lowest expected cost to the MHS.

Cost Effectiveness Conclusion – The P&T Committee accepted the conclusions from the cost effectiveness analyses stated above. In addition, the Committee concluded that the UF scenario that placed finasteride as the sole 5-ARI on the UF was the most cost effective scenario.

COMMITTEE ACTION: The P&T Committee voted (15 for, 0 opposed, 0 abstained, and 2 absent) to accept the 5-ARI relative CEA as presented by the PEC.

C. 5-ARI – UF Recommendations

COMMITTEE ACTION*:* In view of the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of the 5-ARIs, and other relevant factors, the P&T Committee, based upon its collective professional judgment, voted (14 for, 0 opposed, 1 abstained, and 2 absent) to recommend that finasteride be maintained as formulary on the UF and that dutasteride be classified as non-formulary under the UF.

D. 5-ARI – MN Criteria

Based on the clinical evaluation for dutasteride, and the conditions for establishing MN for a non-formulary medication provided for in the UF rule, the P&T Committee recommended the following general MN criteria for dutasteride:

1) Use of formulary alternatives is contraindicated.
2) The patient has experienced significant adverse effects from formulary alternatives.

COMMITTEE ACTION: The P&T Committee voted (14 for, 0 opposed, 1 abstained, 2 absent) to approve the MN criteria outlined above.

E. 5-ARI – UF Implementation Period

Because of the relatively few number of beneficiaries affected (approximately 20,917 patients (41%) of approximately 51,017 beneficiaries at all three points of service), the P&T Committee recommended an effective date of the first Wednesday following a 90-day implementation period. The implementation period will begin immediately following approval by the Director, TMA.

MTFs will not be allowed to have dutasteride on their local formularies. MTFs will be able to fill non-formulary requests for these agents only if both of the following conditions are met: 1) the prescription must be written by a MTF provider, and 2) MN is established. MTFs may (but are not required to) fill a prescription for a non-formulary 5-ARI agent written by a non-MTF provider to whom the patient was referred, as long as MN has been established.

COMMITTEE ACTION: The P&T Committee recommended (14 for, 0 opposed, 1 abstained, 2 absent) an effective date of the first Wednesday following a 90-day implementation period. The implementation period will begin immediately following the approval by the Director, TMA.

F. 5-ARIs – BCF Review and Recommendations

Currently there are no 5-ARI agents on the BCF. The P&T Committee had previously determined at the November 2006 meeting that at least one 5-ARI would be placed on the BCF. Finasteride is widely used at MTFs, has clinical data supporting efficacy for decrease in total prostate volume, increase in urinary flow rate, and improvement in symptoms, reductions in risk of acute urinary retention and BPH-related surgery. Finasteride is clinically similar to dutasteride with respect to safety and tolerability, and is the most cost effective 5-ARI. The P&T Committee agreed that finasteride should be placed on the BCF.

COMMITTEE ACTION: The P&T Committee voted (14 for, 0 opposed, 1 abstained, 2 absent) to recommend adding finasteride as the BCF selection in this class.

8. DRUG CLASS REVIEW – PROTON PUMP INHIBITORS (PPIs)

The P&T Committee evaluated the relative clinical effectiveness of the PPIs. The PPI drug class includes the following agents: esomeprazole (Nexium), lansoprazole (Prevacid), omeprazole (Prilosec and generics), omeprazole/ sodium bicarbonate (Zegerid), omeprazole magnesium (Prilosec OTC), pantoprazole (Protonix), and rabeprazole (Aciphex). Omeprazole magnesium (Prilosec OTC) was added to the UF for purposes of the OTC Demonstration Project as a result of the February 2007 P&T Committee meeting. The PPI class was previously reviewed by the P&T Committee in February 2005.

As of March 07, about 350,000 MHS prescriptions for PPIs are filled per month. This drug class is now #1 in terms of MHS expenditures: more than $485 million over the 12 months from April 06 to March 07, compared to about $350 million in FY 2005. MTF pharmacies dispense 47% of all PPI tablets, compared to 36% dispensed by retail network pharmacies and 17% dispensed by the TMOP. Across the MHS, rabeprazole is the most commonly prescribed PPI, due mainly to its favorable formulary status and high utilization at MTFs. The next four most-prescribed PPIs – lansoprazole, esomeprazole, pantoprazole, and omeprazole – have similar utilization patterns. Of the PPIs, only prescription omeprazole is generically available.

Pharmacologically, PPIs suppress the final step in gastric acid production. They have become the standard of care for treatment of acid-related disorders, particularly treatment of erosive or ulcerative disease.

Standard practice in the initial management of dyspepsia or gastroesophageal reflux disease (GERD) indicates that if certain "alarm features" (i.e., signs of potential underlying cancer such as melena, persistent vomiting, dysphagia, hematemesis, anemia, or involuntary weight loss) are not present, patients should be treated with an empiric trial of 4 to 8 weeks of PPI therapy. In populations where the prevalence of *H. pylori* is greater than 10%, *H. pylori* testing should occur prior to further evaluation, with subsequent treatment if positive. Patients with inadequate symptom relief after 8 weeks should receive endoscopy and further management based on endoscopy results. GERD is often a relapsing-remitting disease which requires long-term medical maintenance therapy; in many cases PPIs will be continued for an extended period of time.

A. PPIs – Relative Clinical Effectiveness

The P&T Committee evaluated the relative clinical effectiveness of the PPIs currently marketed in the U.S. Information regarding the safety, effectiveness, and clinical outcomes of these drugs was considered. The clinical review included, but was not limited to, the requirements stated in the UF Rule, 32 CFR 199.21(e)(1). The P&T Committee was advised that there is a statutory presumption that pharmaceutical agents in a therapeutic class are clinically effective and should be included on the UF, unless the P&T Committee finds by a majority vote that a pharmaceutical agent does not have a significant, clinically meaningful therapeutic advantage in terms of safety, effectiveness, or clinical outcome over the other pharmaceutical agents included on the UF in that therapeutic class.

1) FDA-Approved Indications and Other Uses

All of the PPIs are FDA-approved for the treatment of erosive esophagitis (EE) and maintenance of healed EE. All PPIs except pantoprazole have at least one indication for ulcer treatment (e.g., duodenal or gastric ulcers and/or ulcers associated with non-steroidal anti-inflammatory drugs (NSAIDs) or caused by *H. pylori*). All PPIs except pantoprazole and omeprazole/sodium bicarbonate have an FDA indication as part of a multi-drug regimen for the eradication of *H. pylori*. All PPIs except omeprazole/sodium bicarbonate have an indication for the treatment of hypersecretory conditions such as Zollinger-Ellison.

In practice, most of the agents have published data showing effectiveness for use in any of the acid related disorders, and are commonly prescribed to treat all acid related conditions, regardless of FDA indication. Omeprazole, lansoprazole, and esomeprazole are indicated for use in children.

PPIs are also being studied and used outside the area of acid-related disorders (e.g., for surgical procedure prophylaxis, posterior laryngitis, and chronic cough). More data are needed to support broader use of PPIs for these conditions.

2) Efficacy Measures

Comparative efficacy was evaluated on a disease state basis based on FDA indicated uses of the PPIs. The emphasis was on objective clinical endpoints (ulcer healing, esophagitis healing, maintenance of healing / prevention of disease, and symptomatic resolution) rather than surrogate endpoints (such as pH

measurements, supplemental antacid use and serum drug levels), given the uncertain relationship of surrogate endpoints to clinical outcomes.

3) Clinical Evidence

The review focused primarily on randomized, double-blinded trials where one PPI was compared to another (head-to-head or direct comparison trials), or to another active comparator such as histamine-2 receptor antagonists (e.g., ranitidine, cimetidine, etc). Three good quality systematic reviews summarized the available data, supplemented by more recently published trials. The systematic reviews included PPI reviews from the Oregon Health and Science University's Drug Effectiveness Review Project (DERP; July 2006) and the Canadian Optimal Medication Prescribing and Utilization Service (COMPUS; Aug 2005), and the Agency for Healthcare Research and Quality (AHRQ) 2005 Comparative Effectiveness of Management Strategies for Gastroesophageal Reflux Disease guideline.

It should be noted that no published outcomes evidence is available for either omeprazole magnesium (Prilosec OTC) or the immediate release/sodium bicarbonate (Zegerid) formulations of omeprazole. FDA approval of these formulations relied on the original omeprazole data.

4) Efficacy

a) EE healing

Evidence from head-to-head trials suggests the majority of patients obtain complete healing of erosive disease within eight weeks of treatment on any PPI, with most patients achieving symptom relief within four weeks of initiating treatment.

Of the 25 head-to-head trials published in the clinical literature, only six showed a statistically significant difference in healing rates among the PPIs. One of these predictably found omeprazole 20 mg to be more efficacious than lansoprazole 15 mg, but similar to lansoprazole 30 mg, which is the dose typically used for EE healing.

Two trials comparing esomeprazole and lansoprazole reported differences favoring esomeprazole, with one trial reporting statistically significant differences in healing and symptom resolution at four weeks that disappeared by 8 weeks and the other reporting a small but statistically significant difference in healing and symptom resolution at four weeks and healing at eight weeks. Another head-to-head trial of esomeprazole and lansoprazole showed no significant difference in healing or symptom resolution at the same time points.

Two trials comparing esomeprazole and omeprazole reported differences favoring esomeprazole; both trials compared esomeprazole 40 mg to omeprazole 20 mg, which are not equivalent doses. Two adequately powered later trials, one comparing esomeprazole 40 mg to omeprazole 20 mg and one comparing esomeprazole 20 mg to omeprazole 20 mg, failed to show

statistically significant differences in healing rates at four and eight weeks or symptom resolution at 4 weeks.

One trial comparing esomeprazole to pantoprazole reported differences favoring esomeprazole; this trial appears to have some internal validity issues. Another trial comparing esomeprazole 40 mg and pantoprazole 40 mg failed to find any statistically significant differences in healing or symptom relief.

Conclusion – Although some trials appear to demonstrate superior efficacy for healing of EE with esomeprazole, actual differences are small and inconsistent among trials. Evidence for clinical efficacy is similar enough to consider all agents equally effective in healing of EE.

b) Maintenance of healing in erosive esophagitis

The evidence includes six clinical trials comparing various PPIs, along with a placebo-controlled rabeprazole trial and a comparison of pantoprazole and ranitidine. There are substantial methodological differences among trials (e.g., methods of evaluating healing, duration, study populations, and comparators used), as well as internal validity issues and small trial sizes that make it impossible to draw conclusions regarding the superiority of one agent over another.

Conclusion – There is sufficient evidence to support the use of PPIs for maintenance of initial healing and symptomatic relief of EE for as long as five years. However, the evidence is insufficient to conclude that one PPI is superior to others for maintenance of EE healing.

c) Ulcer healing and maintenance of healing

Fifteen head-to-head trials compared efficacy of various PPIs to omeprazole for initial healing and/or maintenance of healing in duodenal, gastric, and NSAID-induced ulcers. No statistically significant differences were found for any comparators versus omeprazole for primary endpoints of ulcer healing and maintenance of healing or for measures of symptom resolution and improvement.

Conclusion – There appear to be no comparative differences among PPIs for healing, maintenance of healing, or symptom improvement in peptic ulcer disease (PUD) and/or NSAID-induced ulcers.

d) Endoscopy negative reflux disease (ENRD)

ENRD is an incompletely understood variant of GERD. It is estimated that as many as half of patients diagnosed with GERD may fall into this category; however, there are few clinical trials specifically focusing on ENRD. Patients with ENRD are generally considered more difficult to treat than patients with positive findings on endoscopy.

Six trials show efficacy of various healing or maintenance doses of PPIs for initial resolution of heartburn (the primary outcome in all of the trials). Three other trials compare on-demand use of a PPI to placebo or an active

comparator (e.g., a histamine-2 blocker) as continuation therapy after initial resolution of symptoms.

Conclusion – Based on available clinical trials, PPIs appear to be similarly efficacious as short-term treatment for ENRD; there are insufficient data to draw conclusions regarding efficacy for long-term or on-demand treatment.

e) H. pylori eradication with multi-drug regimens

There are at least 39 head-to-head trials comparing all of the PPIs in various multi-drug combination regimens with antibiotics. Substantial differences among studies in doses of PPIs and antibiotics, duration of treatment, methods of assessing *H. pylori* eradication, and patient populations make comparisons across studies difficult. A good quality meta-analysis (2003) using omeprazole as the reference for comparison found no difference in eradication rates among PPIs; earlier systematic reviews (1998, 1999) came to similar conclusions.

Conclusion – H. pylori eradication rates appear similar among PPIs when differing doses of antibiotics and treatment duration are taken into account.

f) Efficacy in Pediatric Patients

Omeprazole, lansoprazole and esomeprazole have indications for treatment of symptomatic GERD in pediatric patients, while omeprazole and lansoprazole have indications for treatment and maintenance of healing of EE. Comparisons of PPIs across trials is difficult; most trials in pediatric patients were small, some were open-label or non-controlled, and surrogate endpoints used to assess symptom resolution varied widely. There was no evidence to support greater efficacy for any one PPI compared to others.

Conclusion – There are insufficient data to suggest superiority of one PPI over others for treatment of pediatric patients. Pantoprazole and rabeprazole do not have an FDA-approved pediatric indication.

5) Safety/Tolerability

a) *Serious adverse events* – A long-standing potential safety concern with PPIs is prolonged hypergastrinemia, which can lead to hyperplasia of both normal and neoplastic enterochromaffin-like cells in the GI tract, potentially leading to cancer. However, the precise role of achlorhydria-induced increases in gastrin expression in gastrointestinal carcinogenesis is unknown. Risk of atrophic gastritis and gastric bacterial overgrowth is increased with long-term PPI use, although the clinical significance is unclear.

PPIs have been associated with *C. difficile* infection, especially in patients taking concomitant antibiotics; caution is particularly indicated with *H. pylori* eradication regimens.

Acute interstitial nephritis has been rarely reported with PPIs. In addition, epidemiological data have suggested an association between PPIs and increased risk of fracture; potential study limitations are numerous, and no definitive evidence is available.

b) *Overall adverse events and withdrawal due to adverse events* – In general, adverse effects are similar to placebo, with an overall incidence rate of less than 5%. Most commonly reported are headache, diarrhea, abdominal pain, and nausea. Head-to-head trials have shown no differences in short-term tolerability; withdrawal rates due to adverse events are very low. There are no clear differences among PPIs with respect to adverse effects or withdrawal rates due to adverse events during clinical trials.

c) *Drug interactions* – PPIs have the potential for causing drug interactions based on several mechanisms, including CYP450 inhibition, effects on the P-glycoprotein membrane transport system in columnar cells of the small intestine, and changes in gastric pH, which can affect absorption of other medications. Omeprazole and esomeprazole may have the most potential for CYP450 drug interactions. Increased effects of warfarin have been reported most frequently with omeprazole, lansoprazole, or pantoprazole, although this is a potential interaction for all PPIs. Most drug interactions are minor in nature.

d) *Special populations* – Dosage adjustments for all PPIs, except pantoprazole, should be considered in patients with severe hepatic disease. None of the PPIs require adjustment in patients with chronic renal insufficiency, elderly patients, or based on gender or race. Omeprazole is classified as Pregnancy Category C; other PPIs are Pregnancy Category B. PPIs are excreted in breast milk and are not recommended for use during breastfeeding.

Zegerid contains 300-460 mg of sodium per tablet due to its sodium bicarbonate component; caution is advised for patients who should avoid consumption of large amounts of sodium.

e) *Other factors* – Lansoprazole, esomeprazole and omeprazole/sodium bicarbonate have dosage forms that can be used in pediatric patients or patients with swallowing difficulties. All three are available as packets for oral suspension; lansoprazole is also available as an orally disintegrating tablet. Omeprazole capsules contain enteric-coated granules commonly used to prepare a bicarbonate-based extemporaneous suspension.

Pantoprazole was the only PPI available in intravenous (IV) form for several years; however, both esomeprazole and lansoprazole have recently developed IV formulations. (It should be noted that due to their route of administration and lack of outpatient use, the IV formulations are not eligible for inclusion on the UF and not included in this review.)

f) *Safety and tolerability conclusion* – The class as a whole is well-tolerated, with an adverse effect profile similar to placebo; most drug interactions are minor in nature. There are no clear differences among PPIs with respect to adverse effects or withdrawal rates due to adverse events during clinical trials. In general, agents appear very similar with respect to safety and tolerability. Minor differences include the lack of a requirement to adjust the dose of pantoprazole in patients with severe hepatic disease (unlike other PPIs); a less favorable pregnancy category rating for omeprazole than the more recently

introduced PPIs (C vs. B); and the availability of liquid dosage forms for esomeprazole, lansoprazole, and omeprazole/sodium bicarbonate.

6) PPIs – Overall Clinical Effectiveness Conclusion:

The P&T Committee concluded that:

a) Based on head-to-head and other controlled trials, PPIs have similar efficacy in a wide range of acid related disorders and are highly therapeutically interchangeable.

b) Although some trials appear to demonstrate superior efficacy for healing of EE with esomeprazole, actual differences are small and inconsistent among trials. Evidence for clinical efficacy is similar enough to consider all agents equally effective in healing of EE.

c) There is sufficient evidence to support the use of PPIs for maintenance of initial healing and symptomatic relief of EE for as long as five years. However, the evidence is insufficient to conclude that one PPI is superior to the others for maintenance of EE healing.

d) There appear to be no comparative differences among PPIs for healing, maintenance of healing, or symptom improvement in PUD and/or NSAID-induced ulcers.

e) Based on available clinical trials, PPIs appear to be similarly efficacious in the short-term treatment of ENRD; there are insufficient data to draw conclusions regarding efficacy for long-term or on-demand treatment.

f) *H. pylori* eradication rates appear similar among PPIs when differing doses of antibiotics and treatment duration are taken into account.

g) There are insufficient data to suggest superiority of one PPI over the others for treatment of pediatric patients; omeprazole, lansoprazole, and esomeprazole have FDA indications for use in pediatric patients.

h) The class as a whole is well-tolerated, with an adverse effect profile similar to placebo; most drug interactions are minor in nature. In general, PPIs appear very similar with respect to safety and tolerability.

i) Minor differences include the lack of a requirement to adjust the dose of pantoprazole (Protonix) in patients with severe hepatic disease (unlike other PPIs); a less favorable pregnancy category rating for omeprazole than the more recently introduced PPIs (C vs. B); and the availability of liquid dosage forms for esomeprazole, lansoprazole, and omeprazole/sodium bicarbonate.

COMMITTEE ACTION: The P&T Committee voted (15 for, 0 opposed, 0 abstained, 2 absent) to accept the clinical effectiveness conclusions stated above.

B. PPIs – Relative Cost Effectiveness

The P&T Committee evaluated the relative cost-effectiveness of the PPIs in relation to efficacy, safety, tolerability, and clinical outcomes of the other agents in the class.

Information considered by the P&T Committee included, but was not limited to, sources of information listed in 32 CFR 199.21(e)(2).

The relative clinical effectiveness evaluation concluded that there was insufficient evidence to suggest that the PPI medications differed in regard to efficacy, safety, tolerability, or clinical outcomes data in the treatment of EE healing and maintenance of healing, ulcer healing and maintenance of healing, *H. pylori* eradication, and ENRD. As a result, several CMAs were performed to compare the relative cost effectiveness of the PPIs by condition set (the seven condition sets are listed below). The CMAs compared the weighted average cost per day of treatment for each potential UF scenario across all three points of service.

1) C7301: Two or fewer PPIs are selected for the UF and one PPI is selected for the BCF. ($\leq$2 UF, 1 BCF)
2) C7302: Three or four PPIs are selected for the UF and one PPI is selected for the BCF. (3-4 UF, 1 BCF)
3) C7303: Three or four PPIs are selected for the UF and two PPIs are selected for the BCF. (3-4 UF, 2 BCF)
4) C7304: Five or more PPIs are selected for the UF and one PPI is selected for the BCF. ($\geq$5 UF, 1 BCF)
5) C7305: Five or more PPIs are selected for the UF and two PPIs are selected for the BCF. ($\geq$5 UF, 2 BCF)
6) C7306: Two PPIs (generic omeprazole and one other PPI) are selected for the UF and generic omeprazole is the only PPI selected for the BCF. In addition, a PA process requires all new PPI users to complete an adequate trial of generic omeprazole before any other PPI is provided to a new user through an MTF pharmacy, the TMOP, or a TRICARE retail network pharmacy.
7) C7307: Two PPIs (generic omeprazole and one other PPI) are selected for the UF. Generic omeprazole will be selected to the BCF and the other PPI may be selected for the BCF. In addition, a PA process requires all new PPI users to complete an adequate trial of generic omeprazole or the second UF PPI before any third tier PPI is provided to a new user through an MTF pharmacy, the TMOP, or a TRICARE retail network pharmacy.

Results from the PPI CMAs showed three important findings: 1) as expected, the more restrictive the UF scenario, the lower the cost per day of treatment; 2) for the three condition sets that evaluated UF scenarios with two or fewer UF agents (C7301, C7306, and C7307), omeprazole and esomeprazole were the most cost effective agents; and 3) for the two condition sets that evaluated UF scenarios with three to four UF agents (C7302 and C7303), omeprazole, esomeprazole, pantoprazole, and rabeprazole were the most cost effective agents.

Based on the results of the clinical review and the pharmacoeconomic evaluations, a BIA of various formulary scenarios was conducted to estimate the influence of other factors associated with a UF decision (i.e., market share migration, switch costs, non-formulary cost-shares). The goal of the BIA was to aid the Committee in

determining which group of PPIs best met the majority of the clinical needs of the DOD population at the lowest expected cost to the MHS.

Cost Effectiveness Conclusion – The DoD P&T Committee accepted the conclusions from the cost effectiveness analyses stated above. In addition, the Committee concluded that the UF scenario (condition set C7307) that maintained omeprazole and esomeprazole as the only two agents on the UF in conjunction with a step therapy PA was the most cost effective scenario.

COMMITTEE ACTION: The DoD P&T Committee voted (14 for, 0 opposed, 0 abstention, and 3 absent) to accept the PPI relative CEA as presented by the PEC.

C. PPIs – UF Recommendations

COMMITTEE ACTION – In view of the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of the PPIs, and other relevant factors, the P&T Committee, based upon its collective professional judgment, voted (14 for, 0 opposed, 1 abstained, and 2 absent) to recommend that: 1) omeprazole and esomeprazole be maintained as formulary on the UF with a PA requiring a trial of either agent for new patients; 2) that rabeprazole, lansoprazole, pantoprazole, and omeprazole/sodium bicarbonate be classified as non-formulary under the UF with a PA requiring a trial of either omeprazole or esomeprazole for new patients; and 3) that the normal brand formulary cost-share of $9.00 for esomeprazole be lowered to the generic formulary cost-share of $3.00.

The authority for the last recommendation is codified in 32 CFR 199.21(j)(3), which states that "when a blanket purchase agreement, incentive price agreement, Government contract, or other circumstances results in a brand pharmaceutical agent being the most cost effective agent for purchase by the Government, the P&T Committee may also designate that the drug be cost-shared at the generic rate." Lowering the cost-share for brand name esomeprazole will provide a greater incentive for beneficiaries to use esomeprazole rather than the less cost effective branded products – rabeprazole, lansoprazole, pantoprazole, or omeprazole/sodium bicarbonate – in the purchased care arena.

D. PPIs – PA Criteria

The P&T Committee agreed that the following PA criteria should apply to PPIs other than omeprazole or esomeprazole. Coverage would be approved if a patient met any of the following criteria:

3) Automated PA criteria:
    a) The patient has received a prescription for any PPI agent at any MHS pharmacy point of service (MTFs, retail network pharmacies, or mail order) during the previous 180 days.
4) PA criteria if automated criteria are not met:
    a) The patient has tried omeprazole or esomeprazole and had an inadequate response or was unable to tolerate treatment due to adverse effects.
    b) Treatment with omeprazole or esomeprazole is contraindicated.

The P&T Committee noted that in order for a patient to receive a non-formulary PPI agent at the formulary cost-share, both the PA and MN criteria must be met. If the PA criteria are met without an approved MN determination, the patient cost-share will be at the non-formulary level. In other words, patients obtaining an approved PA for rabeprazole, lansoprazole, pantoprazole, or omeprazole/sodium bicarbonate would NOT automatically receive it at the formulary cost-share.

COMMITTEE ACTION: The P&T Committee voted (14 for, 0 opposed, 1 abstained, 2 absent) to recommend the PA criteria outlined above.

E. PPIs – MN Criteria

Based on the clinical evaluation and the conditions for establishing MN for a non-formulary medication provided for in the UF rule, the P&T Committee recommended the following general MN criteria for rabeprazole, lansoprazole, pantoprazole, and omeprazole/sodium bicarbonate:

1) Use of formulary alternatives is contraindicated.
2) The patient has experienced significant adverse effects from formulary alternatives.
3) Use of formulary alternatives has resulted in therapeutic failure.

COMMITTEE ACTION: The P&T Committee voted (14 for, 0 opposed, 1 abstained, 2 absent) to approve the MN criteria outlined above.

F. PPIs – UF Implementation Period

Even though a large number of beneficiaries are affected (approximately 453,525 patients [64%] of approximately 702,841 beneficiaries at all three points of service), the P&T Committee recommended an effective date of the first Wednesday following a 90-day implementation period. The P&T Committee believed the considerable cost avoidance associated with this recommendation warranted a more aggressive implementation period. Furthermore, the P&T Committee was anxious to extend the $3.00 cost-share for esomeprazole to beneficiaries as soon as possible. The implementation period will begin immediately following approval by the Director, TMA.

MTFs will not be allowed to have rabeprazole, lansoprazole, pantoprazole, or omeprazole/sodium bicarbonate on their local formularies. MTFs will be able to fill non-formulary requests for these agents only if both of the following conditions are met: 1) the prescription must be written by a MTF provider, and 2) MN is established. MTFs may (but are not required to) fill a prescription for a non-formulary PPI agent written by a non-MTF provider to whom the patient was referred, as long as MN has been established.

COMMITTEE ACTION: The P&T Committee recommended (14 for, 0 opposed, 1 abstained, 2 absent) an effective date of the first Wednesday following a 90-day implementation period. The implementation period will begin immediately following the approval by the Director, TMA.

G. PPIs – BCF Review and Recommendations

Based on the relative clinical effectiveness and cost effectiveness analyses, the P&T Committee voted (14 for, 0 opposed, 1 abstained, 2 absent) to recommend designating generic omeprazole (Prilosec 40 mg specifically omitted) and esomeprazole as the BCF selections in this class.

9. DRUG CLASS REVIEW – ANGIOTENSIN RECEPTOR BLOCKERS (ARBs)

The P&T Committee evaluated the relative clinical effectiveness of the seven angiotensin receptor blockers (ARBs) marketed in the U.S. The ARB drug class is comprised of losartan (Cozaar), irbesartan (Avapro), valsartan (Diovan), candesartan (Atacand), telmisartan (Micardis), eprosartan (Teveten), olmesartan (Benicar) and their respective combinations with hydrochlorothiazide (HCTZ).

Utilization of the ARBs has been steadily increasing in the MHS. The ARB drug class accounted for $137 million in MHS expenditures in FY 2006, and is ranked #10 in terms of total expenditures during that time period. Approximately 140,000 30-day equivalent ARB prescriptions are dispensed monthly in both retail network pharmacies and MTFs; approximately 80,000 30-day equivalent ARB prescriptions are dispensed monthly in the TMOP. The most frequently dispensed ARBs in the MHS are valsartan at 50,000 prescriptions per month and valsartan at 40,000 prescriptions per month. However, the angiotensin converting enzyme (ACE) inhibitor lisinopril is still by far the most frequently prescribed ACE inhibitor or ARB in the MHS, with over 150,000 prescriptions dispensed monthly.

A. ARB Relative Clinical Effectiveness

The P&T Committee evaluated the relative clinical effectiveness of the ARBs marketed in the U.S. by considering information regarding their safety, effectiveness, and clinical outcomes. The clinical review included consideration of pertinent information from a variety of sources determined by the P&T Committee to be relevant and reliable, including but not limited to sources of information listed in 32 CFR 199.21(e)(1).

The ARB drug class was previously evaluated for UF status in February 2005. The P&T Committee focused on efficacy differences with respect to labeled indications, particularly in those areas where a benefit in clinical outcomes (e.g., death, hospitalization for heart failure, decreased need for dialysis or renal transplantation) was demonstrated. The primary areas evaluated were efficacy for hypertension, chronic heart failure (HF), and type 2 diabetic nephropathy.

Evidence of the ARBs for use in indications other than hypertension is difficult to interpret, due to the lack of head to head trials between the ARBs that assess clinical outcomes. There are no head-to-head trials assessing efficacy of the ARBs compared to ACE inhibitors for reducing cardiovascular outcomes in HF or type 2 diabetic nephropathy.

1) Efficacy

a) Efficacy Measures

The P&T Committee considered evidence of benefit in improving clinical outcomes of greater importance than effects on physiologic endpoints when evaluating relative clinical effectiveness differences among ARBs. Clinical outcomes include all-cause mortality, cardiovascular mortality, hospitalization for HF, stroke, development of end stage renal disease (ESRD), need for dialysis, and need for renal transplant. Examples of physiologic endpoints include reduction in blood pressure (BP), changes in pulmonary capillary wedge pressure, changes in urinary protein excretion rate, reduced rate of decline in glomerular filtration rate (GFR), changes in urinary albumin to creatinine ratio, and changes in urinary albumin excretion rate.

b) Hypertension

All seven ARBs are approved by the FDA for treating hypertension. One meta-analysis evaluating the ARBs (with the exception of olmesartan) examined data from over 51 clinical trials enrolling over 12,000 patients with hypertension. The meta-analysis reported that treatment with any ARB reduced systolic blood pressure by 7.5-10 mm Hg and diastolic blood pressure (DBP) by 4.5 to 6.5 mm Hg, compared to placebo (placebo-corrected values). Pooled clinical trial data from seven studies with olmesartan enrolling over 2,600 patients show similar BP reductions to the other six ARBs.

All of the ARBs combinations with HCTZ are approved solely for treatment of hypertension. Joint National Commission (JNC) guidelines for treating hypertension state that many patients will require more than one drug to reach blood pressure goals. Addition of HCTZ to an ARB increases efficacy. Treatment with an ARB as monotherapy results in a 53-63% response rate, based on a goal DBP < 90 mm Hg. The response rate increases to 56-70% with the addition of HCTZ to the ARB.

c) Hypertension and Clinical Outcomes

The ARBs have been evaluated in four large clinical trials to assess efficacy for reducing the risk of cardiovascular events in patients with hypertension. Based on the results of the LIFE trial, losartan is labeled to reduce the risk of stroke in patients with hypertension and left ventricular hypertrophy (LVH), however the benefit does not apply to Africa Americans. The benefits of losartan were likely due to greater reductions in BP compared to that achieved with the comparator drug, atenolol (Tenormin, generics). JNC guidelines mention that several antihypertensive drugs classes, including ACE inhibitors and diuretics, are associated with regression of LVH. Reducing BP is well-proven as an effective mechanism to reduce stroke risk, regardless of the antihypertensive agent administered.

Candesartan was found to reduce non-fatal stroke in the SCOPE trial in elderly patients when compared to placebo. When valsartan was compared to amlodipine (Norvasc) in the VALUE trial, there were no differences noted in

cardiovascular mortality or all-cause mortality between the two drugs, however, there were fewer MIs, fatal strokes, and nonfatal strokes with amlodipine. The beneficial results with amlodipine were attributed to a greater percentage of patients achieving target BP goals vs. valsartan (64% versus 58%). In the Jikei Heart Study, valsartan was found to reduce cardiovascular events and strokes, compared to placebo, in a Japanese population.

Candesartan and valsartan are not currently labeled to reduce cardiovascular outcomes in hypertensive patients. For all four trials (LIFE, SCOPE, VALUE, Jikei Heart Study), differences in blood pressure reduction largely account for reported differences in cardiovascular outcomes of ARBs versus other antihypertensives.

e) Chronic Heart Failure

There are no head to head trials comparing the ARBs for use in chronic heart HF. Two large, randomized, placebo-controlled trials, one each with valsartan and candesartan, demonstrated a reduction in the risk of hospitalization due to chronic HF, a clinically relevant outcome.

Based on the results of the Val-HeFT trial, the FDA approved valsartan for use in patients with heart failure. In the Val-HeFT trial, valsartan treatment resulted in a significant 4.4% absolute risk reduction in HF hospitalizations, vs. placebo. A significant reduction in the primary composite endpoint (all-cause mortality/HF hospitalization) was also seen. The previous limitation in the package insert that valsartan should be restricted for use only in HF patients intolerant of ACE inhibitors has now been removed.

The CHARM trials with candesartan support its use in chronic HF, and it is FDA-approved for this indication. A 4.3% absolute risk reduction in HF hospitalization occurred with candesartan treatment, compared to placebo. A significant reduction in the composite primary endpoint (cardiovascular mortality/HF hospitalization) was also shown.

For the other ARBs, losartan was not superior to captopril in reducing death and HF hospitalization in the ELITE II trial. Two pilot studies are available with irbesartan and telmisartan that show reduction in pulmonary capillary wedge pressure. No trials assessing use of eprosartan or olmesartan in HF have been published.

The P&T Committee agreed that there was no evidence that either valsartan or candesartan were preferable relative to the other for the treatment of chronic HF. Since none of the other ARBs have an indication for HF or evidence showing a reduction in clinically relevant outcomes related to chronic HF, the P&T Committee agreed that valsartan and candesartan were preferable to the other five ARBs for the treatment of HF.

f) Type 2 Diabetic Nephropathy

Patients with type 2 diabetes frequently progress from microalbuminuria to overt proteinuria, with decreasing GFR and eventual development of ESRD.

However, the most common cause of death in diabetic patients is due to cardiovascular complications.

i) Microalbuminuria

Head-to-head trials – Two abstracts noted no difference between telmisartan vs. losartan, and telmisartan vs. valsartan in reducing the rate of decline of renal function, as measured by change in urinary protein excretion ratio. However, neither study has been published in a peer-reviewed journal.

Placebo- or active-controlled trials – Benefits on physiologic outcomes in patients with microalbuminuria have been shown with candesartan, irbesartan, telmisartan and valsartan in small studies with placebo or active comparators (usually an ACE inhibitor or calcium channel blocker). There is no published data evaluating efficacy of eprosartan or olmesartan in either microalbuminuria or nephropathy.

ii) Nephropathy

Two ARBs have shown efficacy in clinical outcomes for patients with overt nephropathy and type 2 diabetes mellitus. Both irbesartan and losartan are labeled for use in patients with type 2 diabetic nephropathy, based on the results of the IDNT and RENAAL trials, respectively.

Treatment with losartan resulted in a significant 16% relative reduction (3.6% absolute risk reduction) in the primary composite endpoint (risk of doubling of serum creatinine, death, and ESRD, defined as the need for dialysis or renal transplant), compared to placebo. In the IDNT trial, a significant 20% relative reduction (6.4% absolute risk reduction) was seen with irbesartan compared to placebo when the same composite endpoint was evaluated.

The P&T Committee agreed that there was no evidence that either irbesartan or losartan were preferable relative to the other in patients with type 2 diabetic nephropathy. Since none of the other ARBs has an indication for HF or evidence showing a reduction in clinically relevant outcomes related to type 2 diabetic nephropathy, the P&T Committee agreed that irbesartan and losartan were preferable to the other five ARBs for reducing the risk of doubling of serum creatinine, death, and ESRD in type 2 diabetic nephropathy.

g) Post MI

Valsartan has an additional indication for use in clinically stable patients with left ventricular systolic dysfunction (LVSD) following an MI, to reduce the risk of MI. FDA approval was based on the VALIANT trial, where valsartan was compared with the ACE inhibitor captopril (Capoten, generics). There was no significant difference between valsartan and captopril in all-cause mortality or cardiovascular mortality post-MI.

Overall, ACE inhibitors have a larger body of evidence supporting a mortality benefit in post-MI patients with LVSD than does valsartan. The aldosterone antagonists spironolactone and eplerenone (Inspra) are also labeled for use or have shown efficacy in the post-MI setting.

2) Safety / Tolerability

The ACE inhibitors and ARBs have similar safety concerns regarding hyperkalemia, elevations of serum creatinine, angioedema, and pregnancy category labeling. The ARBs have an incidence of cough similar to placebo.

These medications are generally well-tolerated, with adverse event rates for all the ARBs similar to placebo in controlled trials. The likelihood of potentially serious adverse events, including hyperkalemia, elevations of serum creatinine, and angioedema, does not appear to differ among agents. Drug interaction profiles are similar. All ARBs are rated pregnancy category C during the first trimester, and pregnancy category D during the second and third trimesters, based on the occurrence of fetal abnormalities with ACE inhibitors. The P&T Committee agreed that there is no evidence that any one ARB is preferable to the others with respect to safety or tolerability.

3) Other Factors

The P&T Committee agreed that although there were no clinically significant differences in minor factors between the ARBs, including twice daily dosing and availability in bulk bottles.

4) DoD Utilization

A data analysis of ARB prescriptions using the Pharmacy Data Transaction Service (PDTS) was conducted to determine DOD ARB utilization by FDA approved indication. FDA-approved indication was based on presence of other background medications in the pharmacy profile, (e.g., evidence of digoxin, a loop diuretic or aldosterone antagonist for HF; and use of insulin, oral diabetic medication or blood glucose test strips for diabetic nephropathy). A two-day cross section of 11,317 patients receiving an ARB or ARB/HCTZ combination on 30-31 Mar 07 found 59% of MHS patients were using the ARB for hypertension, 28% for diabetes, 21% for HF, and 8% for both HF and diabetes.

5) Therapeutic Interchangeability

For hypertension, there is a high degree of therapeutic interchangeability for all seven ARBs. Candesartan and valsartan have a high degree of therapeutic interchangeability for chronic HF. For type 2 diabetic nephropathy, irbesartan and losartan have a high degree of therapeutic interchangeability.

6) Clinical Coverage

To meet the needs of the majority of patients in DoD, ideally the UF would include availability of one ARB with evidence for treating HF, and one ARB with evidence for treating type 2 diabetic nephropathy. A third ARB is not necessarily required, as all the ARBs are effective for hypertension, regardless of whether they have additional labeled indications.

7) ARB Overall Clinical Effectiveness Conclusion

The DoD P&T Committee concluded that:

a) There is no evidence that any one ARB is more efficacious than the others for lowering blood pressure.

b) Although losartan is labeled to reduce the risk of stroke in patients with LVH, JNC guidelines support use of other antihypertensive drugs (e.g., ACE inhibitors, diuretics) in this setting. Differences in blood pressure reduction largely account for differences in cardiovascular outcomes seen in trials comparing ARBs to other antihypertensives.

c) There is no evidence to support clinically significant differences in efficacy between candesartan and valsartan in reducing HF hospitalizations in patients with chronic HF.

d) There is no evidence to support clinically significant differences in efficacy between irbesartan and losartan in improving clinical outcomes (e.g., reducing the risk of doubling of serum creatinine, death, or development of ESRD) in patients with type 2 diabetic nephropathy.

e) Valsartan is the only ARB labeled to reduce death and development of heart failure in post-MI patients with LVSD. However, ACE inhibitors have a larger body of evidence supporting a mortality benefit in post-MI patients with LVSD than valsartan. The aldosterone antagonists spironolactone (Aldactone, generics) and eplerenone are also labeled for use or have shown efficacy in the post-MI setting.

f) There is no evidence that the ARBs differ significantly with regard to safety and tolerability profiles.

g) Based on clinical issues alone, there are no compelling reasons to classify any of the ARBs as nonformulary under the UF.

***COMMITTEE ACTION*:** The P&T Committee voted (15 for, 0 against, 0 abstained, 2 absent) to accept the ARB clinical effectiveness conclusion stated above.

B. ARBs – Relative Cost Effectiveness

The P&T Committee evaluated the relative cost effectiveness of the ARBs in relation to efficacy, safety, tolerability, and clinical outcomes of the other agents in the class. Information considered by the P&T Committee included, but was not limited to, sources of information listed in 32 CFR 199.21(e)(2).

The relative clinical effectiveness evaluation concluded that there was insufficient evidence to suggest that the ARB medications differed in regards to efficacy, safety, or tolerability in the treatment of hypertension. However, several products did have additional clinical outcomes data and FDA approved indications for the treatment of chronic HF (candesartan and valsartan) and type 2 diabetic nephropathy (losartan and irbesartan). The clinical review determined that a UF scenario with an agent from these two additional subgroups would be clinically advantageous. As a result, several CMAs were performed to determine the relative cost effectiveness of the agents by

condition set (3 or fewer agents on the UF, 4 – 5 agents on the UF, and 6 or more agents on the UF) and by indication (hypertension, chronic HF, and type 2 diabetic nephropathy). The CMAs compared the weighted average cost per day of treatment for each drug product across all three points of service.

Results from the ARB CMA showed several important findings: (1) a UF scenario with three or fewer agents on the UF was the most cost effective condition set; (2) telmisartan was the most cost effective agent for the management of hypertension; (3) among agents for the management of chronic HF, candesartan was more cost effective than valsartan when three or fewer agents were included on the UF; and (4) losartan and irbesartan had similar cost effectiveness profiles for the treatment of type 2 diabetic nephropathy.

Based on the results of the clinical review and the pharmacoeconomic evaluations, a BIA of various formulary scenarios was conducted to estimate the influence of other factors associated with a UF decision (i.e., market share migration, switch costs, non-formulary cost-shares). The goal of the BIA was to aid the Committee in determining which group of ARBs best met the majority of the clinical needs of the DoD population at the lowest expected cost to the MHS.

Cost Effectiveness Conclusion – The Committee accepted the conclusions stated above and determined from the BIA that the UF scenario that included candesartan, candesartan/HCTZ, losartan, losartan/HCTZ, telmisartan, and telmisartan/HCTZ was the most cost effective UF scenario.

COMMITTEE ACTION: The DoD P&T Committee voted (15 for, 0 opposed, 0 abstention, and 2 absent) to accept the ARB relative CEA as presented by the PEC.

C. ARBs – UF Recommendations

COMMITTEE ACTION: In view of the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of the ARBs, and other relevant factors, the P&T Committee, based upon its collective professional judgment, voted (14 for, 0 opposed, 1 abstained, and 2 absent) to recommend that candesartan, candesartan/HCTZ, losartan, losartan/HCTZ, telmisartan, and telmisartan/HCTZ be maintained as formulary on the UF and that eprosartan, eprosartan/HCTZ, irbesartan, irbesartan/HCTZ, olmesartan, olmesartan/HCTZ, valsartan and valsartan/HCTZ be classified as non-formulary under the UF.

D. ARBs – MN Criteria

Based on the clinical evaluation for eprosartan, eprosartan/HCTZ, irbesartan, irbesartan/HCTZ, olmesartan, olmesartan/HCTZ, valsartan and valsartan/HCTZ, and the conditions for establishing MN for a non-formulary medication provided for in the UF rule, the P&T Committee recommended the following general MN criteria for eprosartan, eprosartan/HCTZ, irbesartan, irbesartan/HCTZ, olmesartan, olmesartan/HCTZ, valsartan and valsartan/HCTZ:

1) Formulary alternatives are contraindicated.
2) The patient has experienced significant adverse effects from formulary alternatives.

3) Use of formulary alternatives has resulted in therapeutic failure.

4) The patient previously responded to a nonformulary pharmaceutical agent and changing to a formulary pharmaceutical agent would incur an unacceptable clinical risk.

The P&T Committee specifically noted that some circumstances under which criterion #4 might be considered to apply may be for 1) post-MI patients with previous angioedema or other intolerance to ACE inhibitors, who are stabilized on valsartan or valsartan/HCTZ, or 2) chronic HF patients stabilized on a non-formulary ARB or ARB/HCTZ combination for whom changes in therapy might result in destabilization.

COMMITTEE ACTION: The P&T Committee voted (13 for, 1 opposed, 1 abstained, 2 absent) to approve the MN criteria outlined above.

E. ARBs – UF Implementation Period

Because of the large number of beneficiaries affected (approximately 228,000 patients (59%) of approximately 387,000 beneficiaries at all three points of service), the P&T Committee recommended an effective date of the first Wednesday following a 120-day implementation period. The implementation period will begin immediately following approval by the Director, TMA.

MTFs will not be allowed to have eprosartan, eprosartan/HCTZ, irbesartan, irbesartan/HCTZ, olmesartan, olmesartan/HCTZ, valsartan, and valsartan/HCTZ on their local formularies. MTFs will be able to fill non-formulary requests for these agents only if both of the following conditions are met: 1) the prescription must be written by a MTF provider, and 2) MN is established. MTFs may (but are not required to) fill a prescription for a non-formulary ARB agent written by a non-MTF provider to whom the patient was referred, as long as MN has been established.

COMMITTEE ACTION: The P&T Committee recommended (14 for, 0 opposed, 1 abstained, 2 absent) an effective date of the first Wednesday following a 120-day implementation period. The implementation period will begin immediately following the approval by the Director, TMA.

F. ARBs – BCF Review and Recommendation

COMMITTEE ACTION: Based on the results of the clinical and economic evaluations, the P&T Committee voted (14 for, 0 opposed, 1 abstained, and 2 absent) to recommend that telmisartan and telmisartan/HCTZ remain on the BCF.

G. Therapeutic Class Reclassification

The Committee agreed that the ARB class should be reclassified and consolidated with other drug classes that affect the renin-angiotensin system. These include ACE inhibitors, ACE/CCB combinations, ARBs, ARB/CCB combinations, and any newly approved antihypertensives affecting the renin-angiotensin system. The new class will be called the Renin-Angiotensin Antihypertensives (RAAs).

10. QUANTITY LIMITS

A. Mometasone nasal spray (Nasonex) – The current QL for mometasone nasal spray is 1 inhaler (17 gm = 120 sprays) per 30 days or 3 inhalers (51 gm) per 90 days. Nasonex, which was previously indicated only for allergic rhinitis at a maximum dose of 2 sprays in each nostril QD (4 sprays per day), received an indication in late 2004 for the treatment of nasal polyps at a maximum dose of 2 sprays in each nostril twice daily (8 sprays per day). TMOP personnel recently reported an increased number of QL override requests for Nasonex, based on dosing consistent with the nasal polyp indication. Accordingly, the P&T Committee recommended an increase in the QL to accommodate the higher maximum dose for nasal polyps.

COMMITTEE ACTION: The Committee voted (14 for, 0 opposed, 1 abstained, and 2 absent) to recommend that the QL for mometasone nasal spray (Nasonex) be increased to 34 gm (2 inhalers) per 30 days (TRRx), 102 gm (6 inhalers) per 90 days (TMOP), based on daily maximum dosing recommended in product labeling.

B. **Ipratropium nasal spray 0.03% and 0.06% (Atrovent Nasal Spray) –** The current QL for Atrovent nasal spray is a collective limit (including both strengths) of 30 mL per 30 days or 90 mL per 90 days. The 0.03% strength, supplied in 30 mL bottles containing 345 sprays per bottle, is indicated for perennial rhinitis in divided doses of up to 12 sprays per day. Taking into account initial priming (7 sprays), 30 mL would equal 28 days supply, assuming consistent use at the maximum recommended dose. The 0.06% strength, supplied in 15 mL bottles containing 165 sprays per bottle, has two indications: 1) rhinorrhea associated with the common cold at divided doses of up to 16 sprays per day; and 2) rhinorrhea associated with seasonal allergic rhinitis at divided doses of up to 16 sprays per day. Based on the indication for seasonal allergic rhinitis and taking into account initial priming, 30 mL would equal 20 days supply, assuming consistent use at the maximum recommended dose.

The P&T Committee also reviewed data concerning QL rejections for Atrovent 0.03% and 0.06%, indicating that approximately 7% of prescriptions for either strength (about 300 prescriptions per month at retail network pharmacies and the TMOP) are initially rejected by the PDTS based on QLs. This is consistent with recent reports from TMOP of an increased number of QL override requests for Atrovent nasal spray.

Based on these data and given that seasonal allergic rhinitis can last considerably longer than 3 weeks, the P&T Committee agreed that the QL for the higher 0.06% strength should be increased. The P&T Committee also agreed that the QL for the lower 0.03% strength should be increased, but requested follow-up monitoring to determine if the change in QLs unduly affected utilization patterns, since the majority of patients should need no more than 1 inhaler per 30 days.

COMMITTEE ACTION: The Committee voted (13 for, 0 opposed, 2 abstained, and 2 absent) to recommend that 1) the QL for ipratropium nasal spray (Atrovent) be changed from a collective limit to a QL by strength; 2) the QL for the 0.03% strength be increased to 2 inhalers (60 mL) per 30 days (TRRx), 6 inhalers (180 mL) per 90 days (TMOP); and 3) the QL for the 0.06% strength be increased to 3 inhalers (45

mL) per 30 days (TRRx), 9 inhalers (135 mL) per 90 days (TMOP), based on daily maximum dosing recommended in product labeling.

11. RE-EVALUATION OF NON-FORMULARY AGENTS

Amlodipine (Norvasc) was designated non-formulary at the August 2005 P&T Committee meeting. In early 2007, the FDA approved Mylan Pharmaceutical's first-time generic for Norvasc (amlodipine, Pfizer). The price of amlodipine remains high enough that the Committee felt that even the generic was not cost effective relative to other drugs in the calcium channel blocker class. However, as part of its re-evaluation of the non-formulary UF status of amlodipine, the P&T Committee recognized that there will be situations in the future in which it would be helpful if a procedure were in place that allowed reclassification of such a drug from non-formulary to generic in a more expeditious manner than can be accomplished through the normal quarterly P&T Committee cycle. Such a procedure would be advantageous for both the MHS and its beneficiaries. The P&T Committee proposed the following process to more expeditiously reclassify non-formulary agents:

1) For each drug class in which such a reclassification is a possibility, the P&T Committee will recommend criteria under which non-formulary agents will be reclassified as generic agents under the UF. These criteria will be reviewed and adopted as a recommendation of the committee. The recommendation will be subject to comment by the BAP), and final decision by the Director, TMA (see recommended criteria below).
2) When the pre-established criteria for reclassification are met, the Chairperson of the P&T Committee will call for an electronic vote by the members of the P&T Committee on the matter.
3) Upon a majority vote affirming that the non-formulary drug should be reclassified as generic, that agent will be changed from non-formulary status to formulary status as a generic.
4) Committee members will be briefed on any reclassification of a non-formulary agent at the next meeting of the P&T Committee. This information will be recorded as an information-only item in the meeting minutes. The item will be included in information provided for the BAP's next meeting; however, since the BAP will have already made any comments on the subject, the item will normally not be subject to further BAP comment.

The DoD P&T Committee recommended the following criteria for the re-evaluation of non-formulary agents for UF status. These criteria would apply only to drug classes in which UF status was NOT awarded based on condition sets that specified the number of similar agents on the UF (i.e., agents in the same class or subclass). All three criteria must be met for the reclassification of a non-formulary agent.

1) The P&T Committee had concluded previously that the non-formulary agent had similar relative clinical effectiveness (i.e., similar efficacy, safety, and tolerability) compared to similar agents on the UF, and that the drug had not been excluded from the UF based on clinical issues alone.

2) The non-formulary agent becomes generically available and:
   a) The generic product is "A-rated" as therapeutically equivalent to the brand name product according to the FDA's classification system
   b) The generic market supply is stable and sufficient to meet DoD MHS supply demands.
3) The non-formulary agent is cost effective relative to similar agents on the UF. A non-formulary agent becomes cost-effective when:
   a) The non-formulary agent's total weighted average cost per day of treatment is less than or equal to the total weighted average cost per day of treatment for the UF class to which they were compared.
   b) The non-formulary agent's total weighted average cost based on an alternate measure used during the previous review is less than or equal to that for the UF class to which they were compared. F or example, antibiotics may be compared on the cost per course of therapy used to treat a particular condition.

COMMITTEE ACTION: The P&T Committee recommended (14 for, 0 against, 3 absent) that the process and criteria described above should be adopted.

12. CLASS OVERVIEWS

Class overviews for the newer antihistamines, targeted immunomodulatory biologics, leukotriene modifiers, beta/alpha-beta blockers, and alpha blockers for BPH were presented to the P&T Committee. Preliminary information for the technical review for the blood glucose test strips was also presented.

The P&T Committee provided expert opinion regarding those clinical outcomes considered most important for the PEC to use in completing the clinical effectiveness review and developing the appropriate cost effectiveness models. The clinical and economic analyses of these classes will be completed during the August 2007 or November 2007 meetings; no action is necessary.

13. ADJOURNMENT

The second day of the meeting adjourned at 1700 hours on 16 May 2007. The next meeting will be August 14-15, 2007.

BCF = Basic Core Formulary; ECF = Extended Core Formulary; ESI = Express-Scripts, Inc; MN = Medical Necessity; TMOP = TRICARE Mail Order Pharmacy; TRRx = TRICARE Retail Pharmacy program; UF = Uniform Formulary

ER = extended release; IR = immediate release; SR = sustained release; IDD-P = insoluble drug delivery-microParticle

ADHD = Attention Deficit Hyperactivity Disorder; ARBs = Angiotensin Receptor Blockers; ACE Inhibitors = Angiotensin Converting Enzyme Inhibitors; BPH = Benign Prostatic Hyperplasia; CCBs = Calcium Channel Blockers; EE = ethinyl estradiol; GI = gastrointestinal; GABA = gamma-aminobutyric acid; H2 = Histamine-2 receptor; HCTZ = hydrochlorothiazide; MS-DMDs = Multiple Sclerosis Disease-Modifying Drugs; OABs = Overactive Bladder Medications; PDE-5 Inhibitors = Phosphodiesterase-5 inhibitors; PPIs = Proton Pump Inhibitors; TZDs = thiazolidinediones

*The topical antifungal drug class excludes vaginal products and products for onychomycosis (e.g., ciclopirox topical solution [Penlac])

Appendix B – Table 2. Newly Approved Drugs. May 2007 DoD P&T Committee Meeting

Medication (Brand name; manufacturer) mechanism of action	**FDA Approval Date & FDA-Approved Indications**	**Committee Recommendation**
Lapatinib tablets (Tykerb, Glaxo) tyrosine kinase inhibitor	Mar 07 ▪ In combination with capecitabine for treatment of patients with advanced or metastatic breast cancer whose tumors over express HER2, and who have received prior therapy including an anthracycline, a taxane, and trastuzumab.	No UF recommendation at this meeting. Consideration of UF status deferred until oral cancer drugs are reviewed; UF review not anticipated in the next 12 months. Quantity limits recommended: ▪ TMOP o Days supply limit 45 days o 250 mg: 225 tabs per 45 days ▪ Retail Network o Days supply limit 30 days o 250 mg: 150 tabs per 30 days
Vorinostat capsules (Zolinza; Merck) histone deactylase inhibitor	Oct 06 ▪ Treatment of cutaneous manifestations in patients with cutaneous T cell lymphoma (CTCL) who have progressive, persistent, or recurrent disease on or following two systemic therapies.	No UF recommendation at this meeting. Consideration of UF status deferred until oral cancer drugs are reviewed; UF review not anticipated in the next 12 months. Quantity limits recommended: ▪ TMOP o Days supply limit 45 days o 100 mg: 180 caps per 45 days ▪ Retail Network o Days supply limit 30 days o 100 mg: 120 caps per 30 days
Arformoterol inhalation solution (Brovana; Sepracor) inhaled long-acting beta agonist	Oct 06 (launched Apr 07) ▪ Long term twice daily (morning and evening) maintenance treatment of bronchoconstriction in patients with COPD, including chronic bronchitis and emphysema. For use by nebulization only.	No UF recommendation at this meeting. Consideration of UF status deferred until inhaled long-acting beta agonists are reviewed; UF review anticipated in the next 12 months. Quantity limits recommended: ▪ TMOP o 180 unit dose 15 mcg/2 mL vials per 90 days ▪ Retail Network o 60 unit dose 15 mcg/2 mL vials per 30 days

Appendix C – Table 3. Table of Abbreviations

5-ARI	5-alpha reductase inhibitor
ACE	angiotensin converting enzyme
AERS	adverse event reporting system
AHA	American Heart Association
AHRQ	Agency for Healthcare Research and Quality
ARB	angiotensin receptor blocker
AUA	American Urological Association
AUA-SI	American Urological Association symptom index
AUR	acute urinary retention
BAP	Beneficiary Advisory Panel
BAS	bile acid sequestrant
BCF	Basic Core Formulary
BIA	budget impact analysis
BID	twice daily
BPA	blanket purchase agreement
BP	blood pressure
BPH	benign prostatic hyperplasia
CAD	coronary artery disease
CCB	calcium channel blocker
CEA	cost-effectiveness analysis
CFR	Code of Federal Regulations
CHD	coronary heart disease
CMA	cost minimization analysis
COMPUS	Canadian Optimal Medication Prescribing and Utilization Service
CPAP	continuous positive airway pressure
CYP	cytochrome (P450)
DERP	Drug Effectiveness Review Project (state of Oregon)
DHA	docosahexaenoic acid
DHT	dihydrotestosterone
DoD	Department of Defense
DBP	diastolic blood pressure
EE	erosive esophagitis
ENRD	endoscopy-negative reflux disease
EPA	eicosapentaenoic acid
EPICS	Enlarged Prostate International Comparator Study
ESRD	end stage renal disease
ER	extended release
ESI	Express Scripts, Inc.
FDA	Food and Drug Administration
FIELD	Fenofibrate Intervention and Event Lowering in Diabetes trial
FY	fiscal year
GERD	gastroesophageal reflux disease
GI	gastrointestinal
GISSI	Gruppo Italiano per lo Studio della Sopravvivenza nell'Infarcto miocardico (GISSI)-Prevenzione
GFT	glomerular filtration rate
HCTZ	hydrochlorothiazide
HDL	high density lipoprotein
HF	heart failure
HHS	Helsinki Heart Study
IDD-P	Insoluble drug delivery microparticle
IPSS	International Prostate Symptom Score
IV	intravenous

Appendix C – Table 3. Table of Abbreviations (continued)

JNC	Joint National Council
LDL	low density lipoprotein
LH	leutinizing hormone
LIP-2	Antilipidemics II
LRC-CPPT	Lipid Research Clinics – Coronary Primary Prevention Trial
LUTS	lower urinary tract symptoms
LVH	left ventricular hypertrophy
LVSD	left ventricular systolic dysfunction
MHS	Military Health System
MI	myocardial infarction
MN	medical necessity
MTF	military treatment facility
MTOPS	Medical Therapy of Prostatic Symptoms
NCEP	National Cholesterol Education Program
NHLBI	National Heart, Lung, and Blood Institute
NSAIDs	non-steroidal anti-inflammatory drugs
OTC	over-the-counter
PA	prior authorization
PPI	proton pump inhibitor
P&T	Pharmacy and Therapeutics
PDTS	Pharmacy Data Transaction Service
PEC	Pharmacoeconomic Center
PSA	prostate specific antigen
PUD	peptic ulcer disease
QD	once daily

DECISION PAPER

DEPARTMENT OF DEFENSE

PHARMACY AND THERAPEUTICS COMMITTEE RECOMMENDATIONS

February 2007

1. **CONVENING**
2. **ATTENDING**
3. **REVIEW MINUTES OF LAST MEETING**
4. **ITEMS FOR INFORMATION**
5. **REVIEW OF RECENTLY APPROVED AGENTS**

A. Recently Approved Agents in Classes Not Yet Reviewed for the Uniform Formulary (UF) – The Department of Defense (DoD) Pharmacy and Therapeutics (P&T) Committee was briefed on two new drugs approved by the Food and Drug Administration (FDA) that did not fall under drug classes previously reviewed for UF consideration: sitagliptin phosphate tablets (Januvia) and paliperidone extended release [ER] tablets (Invega). UF consideration was deferred until drug class reviews are completed. No action is required since the P&T Committee did not recommend a quantity limits (QL) or prior authorization (PA) for either of these drugs.

B. Over-the-Counter Omeprazole Magnesium (Prilosec OTC)

The John Warner National Defense Authorization Act for FY 2007 directed that the Secretary of Defense conduct a demonstration project to assess the impact of authorizing TRICARE coverage for over-the-counter (OTC) agents recommended for inclusion on the UF. The DoD P&T Committee must find that the OTC drug is cost effective and therapeutically equivalent to prescription alternatives. The P&T Committee, after consultation with the TRICARE Management Activity (TMA) Pharmacy Program office, selected the proton pump inhibitor (PPI) omeprazole magnesium as the initial OTC product. It is projected to be available at military treatment facilities (MTFs) and the mail order points of service by 1 May 2007.

The P&T Committee previously reviewed the PPIs in February 2005. PPIs on the UF include prescription omeprazole (Prilosec, generics), rabeprazole (Aciphex), lansoprazole (Prevacid), and pantoprazole (Protonix). Esomeprazole (Nexium), the s-isomer of omeprazole, is non-formulary under the UF. The Basic Core Formulary (BCF) selections in this class are prescription omeprazole and rabeprazole.

Relative Clinical Effectiveness – The P&T Committee concluded (13 for, 0 opposed, 2 abstained, 2 absent) that omeprazole magnesium has similar relative clinical effectiveness compared to other PPIs included on the UF. The P&T Committee also concluded that, while FDA-approved indications differ for the OTC and prescription versions of omeprazole, there is no reason to believe that the clinical effect of omeprazole magnesium, when given to the same patients in the same doses, would differ from the anticipated effects of prescription omeprazole.

Relative Cost Effectiveness – The cost analysis showed that omeprazole magnesium has a cost effectiveness profile similar to prescription omeprazole in the mail order and MTF points of service and a more favorable cost effectiveness profile in the retail sector. Omeprazole magnesium is more cost effective than other products in the PPI class (i.e., esomeprazole, lansoprazole, pantoprazole, and rabeprazole) across all three points of service. Based on the results of the cost analysis and other clinical and cost considerations, the P&T Committee voted (13 for, 0 opposed, 2 abstained, 2 absent) that omeprazole magnesium is comparable in cost to prescription omeprazole, and more cost effective than the other PPIs included on the UF.

COMMITTEE ACTION: UF RECOMMENDATION – Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of the PPIs, and other relevant factors, the P&T Committee, based upon its collective professional judgment, voted (13 for, 0 opposed, 2 abstained, 2 absent) to recommend that omeprazole magnesium be classified as formulary on the UF (see paragraph 5B on pages 20-22 of the P&T Committee minutes).

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

6. DRUG CLASS REVIEW – NEWER SEDATIVE HYPNOTICS (SED-1s)

The P&T Committee evaluated the relative clinical effectiveness of the newer sedative hypnotic agents (SED-1s). The SED-1 drug class includes the following agents: zolpidem immediate release [IR] (Ambien), eszopiclone (Lunesta), ramelteon (Rozerem), zaleplon (Sonata), and zolpidem ER (Ambien CR). All SED-1 agents except ramelteon are classified as benzodiazepine receptor agonists; ramelteon acts as an agonist at melatonin receptors (MT_1 and MT_2) in the suprachiasmatic nucleus of the brain, which is responsible for regulation of the 24-hour sleep-wake cycle (circadian rhythm). All are FDA-indicated for the treatment of insomnia, although specific labeling differs.

As of December 2006, about four million Military Health System (MHS) prescriptions for these agents are filled per month. The SED-1 drug class was ranked #15 in terms of expenditures in FY 2006 ($111 million)—up from #18 in FY 2005 ($72 million), and #20 in FY 2004 ($54 million). Across the MHS, zolpidem IR is the most commonly prescribed SED-1, with about twice as many prescriptions compared to the next most commonly prescribed SED-1 agent, zolpidem ER, followed closely by eszopiclone. Usage of zaleplon is low and stable, while usage of the most recently introduced agent, ramelteon, is low but increasing. All of the SED-1 agents are brand-only; zolpidem IR is expected to become generically available in April 2007.

Relative Clinical Effectiveness Conclusion: The P&T Committee voted (15 for, 0 opposed, 1 abstained, 1 absent) that:

1) Based on placebo-controlled trials, all SED-1 agents decrease sleep latency to a similar degree. Data supporting the effect of ramelteon on sleep latency appears to be the least robust, both in terms of the number of published studies and the amount of improvement demonstrated versus placebo. Zolpidem IR and eszopiclone have evidence indicating consistent and similar increases in sleep

duration. Zaleplon and ramelteon do not appear to consistently increase sleep duration.

2) Based on three comparative trials, zaleplon appears to decrease sleep latency more than zolpidem IR, but zolpidem IR appears to increase total sleep time more than zaleplon. In one comparative trial, very similar results were reported for eszopiclone versus zolpidem IR with respect to measures of sleep latency and sleep duration.

3) Based on comparative trials, SED-1 agents appear to be similar in efficacy and short-term adverse events, compared to benzodiazepines; benzodiazepines may cause more rebound insomnia. Zolpidem IR appears to be similar in efficacy to the sedating antidepressant trazodone (Desyrel, generics), based on one comparative trial in non-depressed patients; trazodone may result in greater daytime somnolence.

4) There are no consistent data to demonstrate that SED-1 agents have beneficial effects on sleep architecture, compared to placebo.

5) There is insufficient evidence to conclude that SED-1 agents have a major beneficial effect on quality of life, although limited data show improvement in certain domains of the SF-36. There are insufficient comparative data to draw conclusions about individual agents.

6) The SED-1 agents appear to have similar adverse effect profiles and to result in similar rates of discontinuation due to adverse events in clinical trials. Eszopiclone is associated with an unpleasant taste. There do not appear to be any major disadvantages for any one agent with respect to drug-drug interactions. Ramelteon may be less effective in smokers.

7) Daytime sleepiness, impairments in psychomotor function and cognitive function, adverse effects on driving safety, and increased risk for falls may occur with any of the benzodiazepine receptor agonists; there are little or no data for the melatonin receptor agonist ramelteon. Agents with longer half-lives tend to pose a greater risk for these effects. The SED-1 agent with the longest half-life is eszopiclone, 6 hours (up to 9 hours in elderly patients); followed by zolpidem (Ambien, Ambien CR), 2.5-2.8 hours; ramelteon, 1-2.6 hours; and zaleplon, 1 hour. Lower starting doses of all SED-1 agents except ramelteon are recommended in elderly patients.

8) The applicability of driving safety studies reporting impaired performance and increased risk of accidents with a 7.5 mg dose of zopiclone (eszopiclone's racemic parent drug) is unclear, since recommended doses of eszopiclone would be equivalent to zopiclone doses lower than 7.5 mg. There was no reported difference between eszopiclone and zolpidem IR on subjective measures of next day effects based on results of an unpublished trial reported in the FDA statistical review of eszopiclone.

9) Because of its very short half-life, zaleplon may be taken in the middle of the night after a patient has had difficulty falling asleep without demonstrating adverse effects on driving performance the next morning. It may have an

advantage in elderly patients, since risk of falls and hip fracture tends overall to increase with increasing half-life (although the relationship between falls and half-life is not straightforward and prescribers must take into account patient activity patterns).

10) No SED-1 agent appears preferable in other special patient populations (hepatic or renal dysfunction, pregnancy, pediatrics); there is some concern about use of ramelteon in pediatric patients due to possible endocrine effects.

11) Rebound insomnia has been reported in clinical trials with all SED-1 agents except ramelteon; more rebound insomnia was noted with zolpidem IR than with zaleplon during comparative trials.

12) All SED-1 agents, with the exception of ramelteon, probably have a small but significant potential for abuse. Ramelteon appears to lack significant abuse potential and may be preferable in patients at high risk for substance abuse. Ramelteon is the only SED-1 agent that is not a Drug Enforcement Agency (DEA) scheduled substance.

13) It is likely that at least two SED-1 agents are needed for adequate clinical coverage, based on provider responses regarding prescribing practices and likely patient response.

Relative Cost Effectiveness Conclusion: Based on the results of the cost minimization analysis (CMA) and other clinical and cost considerations, the P&T Committee voted (15 for, 0 opposed, 1 abstained, 1 absent) that:

1) Eszopiclone was the most cost effective agent until zolpidem IR becomes generically available with competitive pricing.

2) Ramelteon, zaleplon, and zolpidem ER were more costly than eszopiclone and provided no meaningful clinical therapeutic advantage compared to eszopiclone or zolpidem IR.

3) The UF scenario utilizing a prior authorization requiring a trial of zolpidem IR by new SED-1 patients was more cost effective relative to UF scenarios not requiring a trial of zolpidem IR by new SED-1 patients.

A. COMMITTEE ACTION: UF RECOMMENDATION – Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of the SED-1 agents, and other relevant factors, the P&T Committee, based upon its collective professional judgment, voted (13 for, 1 opposed, 2 abstained, 1 absent) to recommend that: 1) eszopiclone and zolpidem IR be maintained as formulary on the UF with a PA requiring a trial of zolpidem IR for new patients and 2) that ramelteon, zaleplon, and zolpidem ER be classified as non-formulary under the UF, with a PA requiring a trial of zolpidem IR for new patients (see paragraphs 6A, 6B, and 6C on pages 23-31 and Appendix D on page 79 of the P&T Committee minutes).

The Committee agreed that the following PA criteria should apply to SED-1 agents other than zolpidem IR. Coverage would be approved if a patient met any of the following criteria:

1) Automated PA criteria:

The patient has received a prescription for any SED-1 agent (including zolpidem IR) at any MHS pharmacy point of service (MTFs, retail network pharmacies, or mail order) during the previous 180 days.

2) PA criteria if automated criteria are not met:

The patient has tried zolpidem IR and had an inadequate response or was unable to tolerate it due to adverse effects.

Treatment with zolpidem IR is contraindicated.

In order for a patient to receive a non-formulary SED-1 agent at the formulary cost-share, both the PA and medical necessity (MN) criteria must be met. If the PA criteria are met without an approved MN determination, the patient cost-share will be at the non-formulary level. In other words, patients obtaining an approved PA for ramelteon, zaleplon, or zolpidem ER would NOT automatically receive it at the formulary cost-share.

The P&T Committee also noted that the PA is not intended to apply where there are existing policies or protocols in place for operational/readiness situations and that MTFs should make necessary allowances for such use.

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

B. COMMITTEE ACTION: MN CRITERIA – Based on the clinical evaluation for ramelteon, zaleplon, and zolpidem ER, and the conditions for establishing MN for a non-formulary medication provided for in the UF rule, the P&T Committee recommended (15 for, 0 opposed, 1 abstained, 1 absent) MN criteria for ramelteon, zaleplon, and zolpidem ER (see paragraph 6D on page 31 of the P&T Committee minutes).

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

C. COMMITTEE ACTION: IMPLEMENTATION PERIOD – The P&T Committee voted (14 for, 0 opposed, 2 abstained, 1 absent) to recommend an effective date of the greater of 1) the first Wednesday following a 90 day implementation period, or 2) the time necessary to complete logistical arrangements to implement the automated PA. The implementation period will begin immediately following approval by the Director, TMA (see paragraph 6E on pages 31-32 of the P&T Committee minutes).

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

D. COMMITTEE ACTION: BCF RECOMMENDATION – Based on the relative clinical effectiveness and cost effectiveness analyses, the P&T Committee voted (13 for, 0 opposed, 3 abstained, 1 absent) to recommend adding zolpidem IR as the BCF selection in this class (see paragraph 6F on page 32 of the P&T Committee minutes).

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

7. DRUG CLASS REVIEW – NARCOTIC ANALGESICS

The drugs in this class comprise all narcotic analgesics (also referred to as opioids or opiate agonists) used for the treatment of pain on an outpatient basis, including combinations with acetaminophen (APAP), aspirin (ASA), and other non-opioids. Not included in this drug class review are narcotic analgesics given primarily by intravenous injection or infusion, over-the-counter products, products requiring administration by a medical professional, products in which the narcotic component is primarily used as an antitussive, and products indicated solely for the treatment of opioid dependence.

For review purposes, the narcotic analgesics were divided into four categories, based on their potency. Most of these agents are now generically available.

The narcotic analgesics accounted for approximately $153 million dollars in MHS expenditures in FY 2006 and are ranked #8 in terms of total expenditures during that time period. Approximately 437,000 DoD beneficiaries received one or more prescriptions for a narcotic analgesic during FY 2006.

Relative Clinical Effectiveness Conclusion: The P&T Committee voted (15 for, 0 opposed, 1 abstained, 1 absent) that:

1) There is insufficient evidence to support efficacy differences between narcotic analgesics, including high potency long-acting agents for the treatment of chronic cancer or non-cancer pain, high potency IR agents for the treatment of break-through pain, or narcotic analgesics in general for the treatment of neuropathic pain.
2) Strong narcotic analgesics appear to be more effective than non-opioid analgesics (non-steroidal anti-inflammatory drugs [NSAIDs], tricyclic antidepressants [TCAs]) in chronic non-cancer pain.
3) There is no evidence suggesting efficacy differences between long-acting and short-acting formulations of the same agents; however, long-acting products offer greater convenience and may be associated with fewer episodes of breakthrough pain.
4) There is insufficient evidence to support efficacy differences between the 12-hour ER morphine products (e.g., MS Contin and generics) and the 24-hour ER morphine products (Avinza, Kadian), or between the two 24-hour products (Avinza versus Kadian). Avinza is restricted to a maximum dose of 1600 mg daily and cannot be taken with alcohol (including alcohol-containing medications). Kadian has a much longer time to achieve maximum serum levels

(~9.5 hours) compared to Avinza (~0.5 hour) or to 12-hour ER morphine (2-3 hours). Both can be opened and sprinkled on food; Kadian granules can be given via gastrostomy tube.

5) There is insufficient evidence to support efficacy differences between high potency IR agents for the treatment of breakthrough pain in patients with chronic cancer or non-cancer pain, including the newer IR fentanyl products (oral transmucosal lozenges [Actiq, generic] and buccal tablets [Fentora]). Buccal fentanyl is more bioavailable and may offer more consistent dosing; it is also sugar-free. The lack of a 1:1 conversion between the two IR fentanyl products may offer significant potential for medication errors.

6) Narcotic analgesics are rarely considered first line agents for the treatment of neuropathic pain. There is insufficient evidence to support efficacy differences between agents. Evidence of efficacy in various types of neuropathic pain exists for morphine, oxycodone, tramadol, and methadone.

7) There is insufficient direct evidence to draw definitive conclusions regarding the relative efficacy of narcotic analgesics for treatment of acute pain. Dosing of combination agents is limited by their non-opioid ingredient, most commonly acetaminophen. The VA/DoD guideline recommends avoiding meperidine for the treatment of postoperative pain.

8) Narcotic analgesics are associated with multiple adverse effects, including nausea, vomiting, constipation, mood changes, somnolence, urinary retention, pruritis, and oral/dental problems. Respiratory depression is uncommon but potentially serious; the risk is generally small when narcotic analgesics are appropriately titrated, as tolerance rapidly develops.

9) A decrease in seizure threshold occurs with the use of all narcotics, but is of particular concern with meperidine (which has a neurotoxic metabolite and should not be used for more than two days in patients with renal impairment, sickle-cell disease, central nervous system [CNS] disease, or in children); propoxyphene (which also has CNS-excitatory metabolites and can cause seizure in high doses, especially in patients with renal disease); and tramadol (which is associated with an increased risk of seizure at higher than recommended doses [300-400 mg daily] or in patients taking other medications or with conditions that increase seizure risk).

10) Propoxyphene is not considered appropriate in elderly patients due to CNS adverse effects, including sedation, confusion, and increased likelihood of falls and fall-related fractures. The consumer watchdog group Public Citizen has petitioned the FDA to phase out propoxyphene from the U.S. market due to the association of excessive doses of propoxyphene with drug-related deaths. Many DoD providers surveyed cited concerns over safety with the use of meperidine and propoxyphene, although others pointed out that they were useful and could be used safely if limited to short-term use in the correct patients.

11) While there are clearly differences among narcotic analgesics with regard to likelihood for abuse (e.g., onset of action and potency), there are no data

supporting differences in potential for abuse among like medications (e.g., high potency long-acting agents) that the P&T Committee considered useful for making any formulary recommendation.

12) In general, drug interactions are relatively similar for all of the drugs in this class and it does not appear that any particular medication offers a substantially higher potential for drug interactions. Two unique considerations are tramadol and meperidine. Because of its dual mechanism of action, tramadol has potential interactions with other medications that increase serotonin and/or norepinephrine levels (e.g., monoamine oxidase inhibitors [MAOIs] and selective serotonin reuptake inhibitors [SSRIs]); meperidine is contraindicated with MAOIs due to the potential for a lethal hyperpyrexic syndrome.

13) There are differences among narcotic analgesics with regard to clinical evidence, extent of clinical experience, and labeling for use in special patient populations (including pediatric and elderly patients, patients who are pregnant or breast-feeding, and patients with renal or hepatic dysfunction). However, the P&T Committee overall did not find sufficient evidence of a unique advantage or disadvantage for specific products that it considered useful for formulary decision-making.

14) Patients with swallowing difficulties may require liquid formulations or products that can be sprinkled on food or administered via a non-oral route. The available narcotic analgesics offer various formulations that meet these needs.

15) Providers surveyed in general emphasized that they require a broad array of narcotic analgesics in their practice to treat their patients and that excessive formulary restrictions would be detrimental to their ability to adequately treat various clinical presentations. They favored ER narcotic analgesics, including the fentanyl transdermal patch, as well as a broad array of strengths of opioid/ acetaminophen combination products. Many pharmacists indicated that centralized contracting for "pre-packed" products in commonly dispensed quantities would facilitate inventory and dispensing at their facilities.

16) Clinical coverage considerations support a broad array of formulary agents and formulations.

Relative Cost Effectiveness Conclusion: Based on the results of the CMAs and other clinical and cost considerations, the P&T Committee voted (14 for, 0 opposed, 1 abstained, 1 absent) that:

1) *High potency long-acting single analgesic agents* – Although the 24-hour ER products (Kadian and Avinza); fentanyl transdermal patch (Duragesic, generics), oxycodone ER (Oxycontin), and oxymorphone (Opana ER) were considerably more costly relative to the 12-hour morphine sulfate ER product (MS Contin and generics), they possess unique clinical advantages and should be maintained on the UF in order to sufficiently meet the clinical needs of the DoD population.

2) *High potency short-acting single analgesic agents* – Even though fentanyl citrate buccal tablets and fentanyl citrate transmucosal lozenges were more than 40-fold the cost of the two most cost effective agents (morphine sulfate IR and oxycodone

IR), the fentanyl citrate products provide an additional therapeutic alternative for breakthrough pain with novel routes of administration. There was no substantial difference in cost effectiveness between the two fentanyl citrate products.

3) *Low potency single analgesic agents* – Tramadol ER (Ultram ER) was not cost effective relative to other formulations of tramadol (tramadol; tramadol/APAP), which are generically available. All other products in this subclass were cost effective.

4) *Combination agents* – The products within this generic-dominated subclass were all determined to be cost effective relative to their comparators.

A. COMMITTEE ACTION: UF RECOMMENDATION – Taking into consideration the conclusions from the relative clinical effectiveness and the relative cost effectiveness determinations for the narcotic analgesic drug class, and other relevant factors, the P&T Committee recommended (14 for, 0 opposed, 1 abstained, 2 absent) that tramadol ER be designated non-formulary under the UF, with all other narcotic analgesic agents designated as formulary on the UF. Additionally, the P&T Committee voted to recommend (14 for, 0 opposed, 1 abstained, 1 absent) a QL of 112 tablets/28 days for fentanyl buccal tablets, consistent with established QLs for fentanyl transmucosal lozenges, recommendations in Fentora package labeling recommending a maximum of four tablets per day, and current DoD prescribing patterns for Fentora buccal tablets (see paragraphs 7A, 7B, and 7C on pages 35-51 of the P&T Committee minutes).

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

B. COMMITTEE ACTION: MN CRITERIA – Based on the clinical evaluation for tramadol ER, and the conditions for establishing MN for a non-formulary medication provided for in the UF rule, the P&T Committee recommended (13 for, 0 opposed, 1 abstained, 3 absent) MN criteria for tramadol ER (see paragraph 7D on page 51 of the P&T Committee minutes).

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

C. COMMITTEE ACTION: IMPLEMENTATION PERIOD – The P&T Committee voted (13 for, 0 opposed, 1 abstained, 3 absent) to recommend an effective date of the first Wednesday following a 90-day implementation period. The implementation period will begin immediately following approval by the Director, TMA (see paragraph 7E on pages 51-52 of the P&T Committee minutes).

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

D. COMMITTEE ACTION: BCF RECOMMENDATION – Based on the relative clinical effectiveness and cost effectiveness analyses, the P&T Committee voted (14 for, 0 opposed, 1 abstained, 2 absent) to recommend designating the following medications as the BCF selections in this class: morphine sulfate ER (MS Contin, generics) 15 mg, 30 mg, 60 mg; morphine sulfate IR 15 mg and 30 mg; oxycodone/ APAP 5/325 mg; hydrocodone/APAP 5/500 mg; codeine/APAP 30/300 mg; codeine/ APAP elixir 12/120 mg/5 mL; and tramadol IR 50 mg (see paragraph 7F on page 52 of the P&T Committee minutes).

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

8. DRUG CLASS REVIEW – OPHTHALMIC GLAUCOMA AGENTS

The P&T Committee evaluated the relative clinical effectiveness of the ophthalmic glaucoma agents available in the U.S. Based on chemical structure and mechanism of action, the drug class was divided into seven subgroups: ophthalmic prostaglandin analogs; beta blockers; carbonic anhydrase inhibitors and combinations with beta blockers; alpha 2 adrenergic drugs; adrenergics; cholinergics; and cholinesterase inhibitors. The ophthalmic glaucoma agent drug class accounted for $51.1 million in MHS expenditures for the period October 2005 to September 2006, and is ranked #34 in terms of total expenditures during that time period.

Relative Clinical Effectiveness Conclusion – The P&T Committee voted (15 for, 0 opposed, 1 abstained, 1 absent) that:

1) *Prostaglandin analogs* – Bimatoprost (Lumigan), latanoprost (Xalatan), and travoprost (Travatan, Travatan Z) all decrease intraocular pressure (IOP) from baseline by 28% to 33%. A prospectively designed trial assessing efficacy of bimatoprost and travoprost found no difference in efficacy in African Americans; a sub-group analysis from a different trial reported decreased efficacy of latanoprost when compared to travoprost in African Americans versus non-African Americans. Latanoprost has the most favorable ocular adverse event profile of the three prostaglandin analogs, but requires refrigeration prior to opening. The non-benzalkonium (BAK) preservative found in the Travatan Z formulation of travoprost has not shown a major advantage in terms of ocular side effects, compared to the BAK-containing product Travatan.

2) *Beta blockers* – The IOP lowering effects of timolol maleate (Timoptic, generics; Timoptic XE, generics), timolol hemihydrate (Betimol), levobunolol (Betagan, generics), metipranolol (Optipranolol, generics) and carteolol (Ocupress, generics) appear similar based on several head-to-head studies. Timolol maleate solution (Timoptic, generics) and gel-forming solution (Timoptic XE, generics) reduce IOP by 20-35%. The Timoptic XE gel-forming solution has the advantage of once daily dosing, but is associated with transient blurred vision due to the consistency of the gel. There is no evidence that the timolol maleate product Istalol or the timolol hemihydrate product Betimol have additional clinical benefits over other timolol maleate products in IOP lowering or safety profiles.

Betaxolol (Betoptic, generics; Betoptic-S) decreases IOP to a lesser extent than timolol maleate; however, the β1 selectivity of betaxolol may be an advantage in patients with cardiac or pulmonary co-morbidities.

3) *Carbonic anhydrase inhibitors* – The IOP lowering effects of brinzolamide (Azopt) and dorzolamide (Trusopt) appear similar. Dorzolamide/timolol (Cosopt) is the only combination product for glaucoma and offers a convenience to patients. Dorzolamide causes more local ocular irritation than brinzolamide; however the burning and stinging upon instillation lasts less than ten seconds, diminish over time, and has not translated into a higher discontinuation rate due to adverse events.

4) *Alpha 2 adrenergics* – Apraclonidine (Iopidine) is used primarily short-term following ocular surgery, while brimonidine is used chronically for glaucoma. Both apraclonidine and brimonidine lower IOP to similar extent. For brimonidine, changing the BAK preservative (generic) to a purite preservative (Alphagan P) and reducing the concentration from 0.2% to 0.15% or 0.1% does not appear to affect efficacy. There are conflicting data as to whether brimonidine purite 0.15% (Alphagan P) causes less ocular irritation than brimonidine BAK 0.2% (generic). In an unpublished trial, brimonidine purite 0.1% (Alphagan P) demonstrated an improved safety and tolerability profile compared to brimonidine BAK 0.2% (generic).

5) *Adrenergics, cholinergics, and cholinesterase inhibitors* – The cholinergic pilocarpine (Pilocar, generics; Pilopine HS gel) is used for acute angle closure glaucoma and as a miotic agent during ocular surgery. Although not routinely used today, the adrenergic drug dipivefrin (Propine), the cholinergics acetyl-choline (Miochol-E) and carbachol (Isopto Carbachol) and the cholinesterase inhibitor echothiophate (Phospholine Iodide) serve unique niches in therapy.

6) Based on clinical issues alone, there are no compelling reasons to classify any of the glaucoma drugs as non-formulary on the UF.

Relative Cost Effectiveness Conclusion: Based on the results of several CMAs, the P&T Committee voted (15 for, 0 opposed, 1 abstained, 1 absent) that:

1) The CMAs compared the weighted average cost per day of treatment for each drug product. For the prostaglandin analogs: a) travoprost (Travatan, Travatan Z) was most cost effective under a scenario where it was the sole agent on the uniform formulary; b) latanoprost and bimatoprost were most cost effective under a scenario where only two prostaglandin products were placed in the UF; and c) an all-on scenario (i.e., all three prostaglandin products were included on the UF) was less cost effective than a scenario where at least one prostaglandin was designated non-formulary.

2) For the other ophthalmic glaucoma agents, only two products were identified as not cost effective in the beta-blocker subclass. Timolol hemihydrate (Betimol) and timolol maleate (Istalol) were both shown to be significantly more costly and no more effective than other agents in the subclass. Similarly, a comparison of the topical carbonic anhydrase inhibitors showed that brinzolamide was not cost

effective compared to dorzolamide. All other medications in the remaining subclasses were determined to be cost effective relative to their comparators.

A. COMMITTEE ACTION: UF RECOMMENDATION – In view of the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of the ophthalmic glaucoma agents, and other relevant factors, the P&T Committee, based upon its collective professional judgment, voted (15 for, 0 opposed, 1 abstained, and 1 absent) to recommend that latanoprost, bimatoprost, levobunolol, betaxolol, carteolol, timolol maleate (Timoptic, generics), timolol maleate gel-forming solution, brimonidine, apraclonidine, dorzolamide, dorzolamide/timolol, dipivefrin, acetylcholine, carbachol, pilocarpine, echothiophate be maintained as formulary on the UF and that travoprost (Travatan, Travatan Z), timolol hemihydrate, timolol maleate (Istalol) and brinzolamide be classified as non-formulary under the UF (see paragraphs 8A, 8B and 8C on pages 52-64 of the P&T Committee minutes).

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

B. COMMITTEE ACTION: MN CRITERIA – Based on the clinical evaluation for travoprost, timolol hemihydrate, timolol maleate (Istalol) and brinzolamide, and the conditions for establishing MN for a non-formulary medication provided for in the UF rule, the P&T Committee recommended (14 for, 0 opposed, 1 abstained, 2 absent) MN criteria for travoprost, timolol hemihydrate, timolol maleate (Istalol) and brinzolamide (see paragraph 8D on pages 64-65 of the P&T Committee minutes).

Approved, but modified as follows:

D. COMMITTEE ACTION: BCF RECOMMENDATION – The P&T Committee considered the BCF status of the ophthalmic glaucoma agents. Based on the results of the clinical and economic evaluations presented, the P&T Committee voted (15 for, 0 opposed, 1 abstained, 1 absent) to recommend that the BCF include latanoprost; brimonidine, excluding the 0.1% strength; timolol maleate (Timoptic, generics) 0.25% and 0.5%; timolol maleate gel-forming solution 0.25% and 0.5% (Timoptic XE, generics); and pilocarpine (see paragraph 8F on page 65 of the P&T Committee minutes).

9. DRUG CLASS REVIEW – MAOI ANTIDEPRESSANTS

The P&T Committee evaluated the relative clinical effectiveness and cost effectiveness of the MAOI antidepressants marketed in the U.S. The drugs in the MAOI antidepressant class include three oral agents, isocarboxazid (Marplan), phenelzine (Nardil), and tranylcypromine (Parnate, generics); and one transdermal patch, selegiline (Emsam). Tranylcypromine is the only drug in the MAOI antidepressant class available in a generic formulation. All of the drugs are available in oral dosage forms; however, oral selegiline capsules are excluded from the review, since they are indicated for use in Parkinson's Disease and not depression. The three oral MAOI antidepressants were first introduced to the market in the early 1960s, while transdermal selegiline was launched in 2006. The MAOI antidepressants accounted for approximately $283,000 dollars in expenditures in FY 2006, which comprises less than 1% of total MHS expenditures for all antidepressant drug classes.

Relative Clinical Effectiveness Conclusion: The P&T Committee voted (15 for, 0 opposed, 0 abstained, 2 absent) that:

1) The oral MAOI antidepressants isocarboxazid, phenelzine, and tranylcypromine have been marketed for several decades, but have been replaced by newer drug classes (e.g., SSRIs) with more favorable adverse event profiles.
2) Transdermal selegiline is the newest MAOI antidepressant marketed. The non-oral formulation was developed to reduce the risk of hypertensive crisis from dietary tyramine.
3) There do not appear to be major differences in clinical efficacy between the three oral MAOIs when used for depression, based on the results of one meta-analysis showing response rates ranging between 53% to 61%, and one inpatient clinical trial.
4) Response rates ranging from 27% to 30% were reported with transdermal selegiline in three placebo controlled trials. There are no clinical trials directly comparing the oral MAOI antidepressants with transdermal selegiline. However, there are no data to suggest that treatment with transdermal selegiline would result in improved response rates compared to the oral MAOI antidepressants.
5) The MAOI antidepressants have a safety profile that is well recognized in terms of drug-drug and drug-food interactions, and these adverse events also apply to transdermal selegiline. Local application site reactions are common with transdermal selegiline.
6) The purported benefits of transdermal selegiline in terms of loosened dietary tyramine restrictions have only been shown clinically with the lowest dose (6 mg/24 hour). Dietary precautions are required with oral MAOIs and with the 9 mg/24 hr and 12 mg/24 hr dosages of transdermal selegiline.

7) Off-label usage of transdermal selegiline is anticipated for treating patients with Parkinson's Disease.

8) The primary advantage of transdermal selegiline is for patients unable to swallow oral medications and require a once-daily dosage formulation.

9) There is insufficient evidence to determine whether transdermal selegiline represents a therapeutic advance over isocarboxazid, phenelzine and tranylcypromine.

10) Based on clinical issues alone, there are no reasons to designate any of the MAOI antidepressants (phenelzine, isocarboxazid, or tranylcypromine, and transdermal selegiline) as non-formulary on the UF.

Relative Cost Effectiveness Conclusion - The P&T Committee voted (15 for, 0 opposed, 0 abstained, 2 absent) that:

1) The oral MAOIs demonstrate similar relative cost effectiveness, with phenelzine as the most cost effective agent.

2) Transdermal selegiline is not cost effective relative to the other agents in the class in the treatment of depression and provides no clinically meaningful therapeutic advantage to justify the increased cost.

A. COMMITTEE ACTION: UF RECOMMENDATION – Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of the MAOI antidepressants, and other relevant factors, the P&T Committee, based upon its collective professional judgment, voted (14 for, 0 opposed, 1 abstained, 2 absent) to recommend that isocarboxazid, phenelzine and tranylcypromine be maintained as formulary on the UF, and that transdermal selegiline be classified as non-formulary under the UF (see paragraphs 9A, 9B, and 9C on pages 66-71 of the P&T Committee minutes).

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

B. COMMITTEE ACTION: MN CRITERIA – Based on the clinical evaluation for MN criteria for transdermal selegiline, and the conditions for establishing MN for a non-formulary medication provided for in the UF rule, the P&T Committee recommended (14 for, 0 opposed, 1 abstained, 2 absent) MN criteria for transdermal selegiline (see paragraph 9D on page 71 of the P&T Committee minutes).

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

C. COMMITTEE ACTION: IMPLEMENTATION PERIOD – The P&T Committee voted (14 for, 0 opposed, 1 abstained, 2 absent) to recommend an effective date of the first Wednesday following a 90-day implementation period. The implementation

period will begin immediately following approval by the Director, TMA (see paragraph 9E on pages 71-72 of the P&T Committee minutes).

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

D. COMMITTEE ACTION: EXTENDED CORE FORMULARY (ECF) RECOMMENDATION – The P&T Committee had previously determined at the November 2006 meeting that one MAOI antidepressant should be added to the ECF based on the clinical and cost effectiveness review. The P&T Committee voted (14 for, 0 opposed, 1 abstained, 2 absent) to recommend that phenelzine be classified as the ECF agent (see paragraph 9F on pages 71-72 of the P&T Committee minutes).

Department of Defense
Pharmacy and Therapeutics Committee Minutes
February 2007

1. CONVENING

The Department of Defense (DoD) Pharmacy and Therapeutics (P&T) Committee convened at 0800 hours on 13-14 February 2007 at the DoD Pharmacoeconomic Center (PEC), Fort Sam Houston, Texas.

2. ATTENDANCE

A. Voting Members Present

CAPT Patricia Buss, MC, USN	DoD P&T Committee Chair
CAPT Mark Richerson, MSC, USN	DoD P&T Committee Recorder
CAPT William Blanche, MSC, USN	DoD Pharmacy Programs, TMA
Lt Col Roger Piepenbrink, MC	Air Force, Internal Medicine Physician
Maj Michael Proffitt, MC	Air Force, OB/GYN Physician
Lt Col Brian Crownover, MC	Air Force, Physician at Large
Lt Col Charlene Reith *for* Lt Col Everett McAllister, BSC	Air Force, Pharmacy Officer
No representative *for* LCDR Michelle Perrello, MC	Navy, Internal Medicine Physician
LCDR Scott Akins, MC	Navy, Pediatric Physician
CDR David Tanen, MC	Navy, Physician at Large
CAPT David Price, MSC	Navy, Pharmacy Officer
COL Doreen Lounsbery, MC	Army, Internal Medicine Physician
MAJ Roger Brockbank, MC	Army, Family Practice Physician
COL Ted Cieslak, MC	Army, Physician at Large
LTC Peter Bulatao, MSC for COL Isiah Harper, MSC	Army, Pharmacy Officer
CAPT Vernon Lew, USPHS	Coast Guard, Pharmacy Officer
Mr. Joe Canzolino, RPh.	Department of Veterans Affairs

B. Voting Members Absent

LCDR Michelle Perrello, MC	Navy, Internal Medicine Physician

C. Non-Voting Members Present

COL Kent Maneval, MSC, USA	Defense Medical Standardization Board
Maj Chang Chinran, NC, USAF	Health Plans Operations, TMA
Lt Col Paul Hoerner, BSC, USAF	Deputy Director, DoD Patient Safety Center
CPT Alvin Blackmon, MSC, USA	Defense Supply Center Philadelphia
Mr. Lynn T. Burleson	Assistant General Counsel, TMA
LT Thomas Jenkins, MSC, USN	TMOP/TRRx COR

D. Non-Voting Members Absent

None	

E. Others Present

Col Nancy Misel, BSC, USAF	IMA DoD Pharmacoeconomic Center
CAPT Don Nichols, MC, USN	DoD Pharmacoeconomic Center
Lt Col James McCrary, MC, USAF	DoD Pharmacoeconomic Center
Maj Wade Tiller, BSC, USAF	DoD Pharmacoeconomic Center
Maj Josh Devine, BSC, USAF	DoD Pharmacoeconomic Center
LCDR Joe Lawrence, MSC, USN	DoD Pharmacoeconomic Center
CPT Josh Napier, MC, USA	DoD Pharmacoeconomic Center
SFC Daniel Dulak, USA	DoD Pharmacoeconomic Center
Shana Trice, Pharm.D.	DoD Pharmacoeconomic Center
David Bretzke, Pharm.D.	DoD Pharmacoeconomic Center
Angela Allerman, Pharm.D.	DoD Pharmacoeconomic Center
Eugene Moore, Pharm.D.	DoD Pharmacoeconomic Center
Julie Liss, Pharm.D.	DoD Pharmacoeconomic Center
Elizabeth Hearin, Pharm.D.	DoD Pharmacoeconomic Center
David Meade, Pharm.D.	DoD Pharmacoeconomic Center
Harsha Mistry, Pharm.D.	DoD Pharmacoeconomic Center
Mark Geraci, Pharm.D.	VAPBM
Capt Jeremy King, MC, USAF	WHMC

3. REVIEW MINUTES OF LAST MEETING

A. Corrections to the Minutes – November 2006 DoD P&T Committee meeting minutes were approved as written, with no corrections noted.

B. Approval of November Minutes - Dr. William Winkenwerder, Jr., M.D., approved the minutes of the November 2006 DoD P&T Committee meeting on 17 January 2007.

4. ITEMS FOR INFORMATION

TRICARE Management Activity (TMA) and DoD PEC staff members briefed the P&T Committee on the following:

A. Beneficiary Advisory Panel (BAP) Briefing – CAPT Buss and CAPT Richerson briefed the members of the P&T Committee regarding the December 2006 BAP meeting. The P&T Committee was briefed on BAP comments regarding the DoD P&T Committee's Uniform Formulary (UF) and implementation recommendations.

B. Implementation Status of UF Decisions – The PEC briefed the members of the P&T Committee on the progress of implementation for drug classes reviewed for UF status since February 2005.

C. Status of Exenatide (Byetta) Prior Authorization (PA) – The PEC briefed the members of the P&T Committee on preliminary results of implementing the PA for exenatide, which went into effect 31 January 2007. The exenatide PA represents the first use of the new automated profile review capability in the Pharmacy Data Transaction Service (PDTS), which enables PA criteria to be automated based on a "look-back" at patient profiles during a given period. The percent of patients automatically approved through the automated process during the first few days the exenatide PA was in place was consistent with previous estimates; the process appears to be functioning as designed.

D. Administrative Action: PA Criteria for Exenatide – The PEC notified the P&T Committee of a December 2006 change in Food and Drug Administration (FDA)-approved labeling for exenatide. The new labeling states that exenatide is indicated as adjunctive therapy to improve glycemic control in patients with type 2 diabetes mellitus who are taking metformin, a sulfonylurea, *a thiazolidinedione,* a combination of metformin and a sulfonylurea, *or a combination of metformin and a thiazolidine-dione*, but have not achieved adequate glycemic control. Italicized text indicates changes in labeling. The P&T Committee ratified the corresponding changes to exenatide PA criteria made under the auspices of the Executive Council, which were accomplished prior to implementation of the PA on 31 January 2007.

E. Status of Fentanyl Patch PA – The P&T Committee discussed implementation of the PA for fentanyl patch recommended at the November 2006 meeting and approved by the Director, TMA in January 2007. The Committee clarified the "look-back" period and definition of prior opioid use that will be used by the automated PA review process. The specific automated PA criteria that will be applied to all fentanyl prescriptions will be the following:

- Patient is likely to be opioid-tolerant based on receiving at least one prescription for one of the following strong opioids (fentanyl patch, morphine, oxycodone (not including combination products), hydromorphone, methadone, or oxymorphone) during the last 60 days.

The P&T Committee reached this conclusion after reviewing estimates of the number and percent of fentanyl patch patients that would be affected by the PA, including the number of patients who had received fentanyl patch prescriptions during the last 120 days, but not within the last 60 days. The P&T Committee agreed that the best trade-

off between ensuring safety and potentially interrupting therapy for established patients would be to allow pharmacists at retail network pharmacies the ability to override the system warning after determining that the patient could be presumed to be opioid tolerant based on information from the patient or the physician. The retail network pharmacist would also have the option of having Express Scripts, Inc. (ESI) handle the PA by advising patients to have their physicians contact ESI.

F. UF Request Process – The P&T Committee approved a request form to be used by military treatment facility (MTF) healthcare providers requesting consideration of potential changes to the Basic Core Formulary (BCF)**,** Extended Core Formulary (ECF), or UF, including changes to medical necessity (MN) criteria for non-formulary medications, prior authorization criteria, or quantity limits. The three general process points previously agreed upon by the P&T Committee will apply:

- Requests will require review and concurrence by the local MTF P&T Committee.
- Requests will be required to contain adequate supporting evidence, including a fair, balanced, and thorough discussion of the relevant clinical literature, and present a rational argument supporting suggested changes.
- Requestors will be required to explain potential conflicts of interest and certify that the request was not initiated or unduly influenced by pharmaceutical industry representatives.

G. Regulatory Status of Pseudoephedrine (PSE) Products – The PEC briefed the committee on the Methamphetamine Anti-Proliferation Act (MAPA), part of the Children's Health Act of 2000; the Combat Methamphetamine Epidemic Act (CMEA) of 2005; and Oregon House Bill 2485 (2005). These three pieces of legislation were enacted to address the diversion of drug products containing PSE, ephedrine and phenylpropanolamine (PPA) for the illicit production of methamphetamine. (PPA has been removed from the human drug market but remains available for veterinary use.)

The CMEA requires pharmacies and other sellers to place PSE products behind the counter; check the identity of purchasers; maintain a log of each sale that includes the purchaser's name and address, signature of the purchaser, product sold, quantity sold, date, and time; maintain the logbook for at least two years; train employees in the requirements of the law; and certify to the Drug Enforcement Agency (DEA) that the training has occurred. Most states have enacted similar legislation.

The State of Oregon passed Oregon House Bill 2485 (2005), which stipulated that the State Board of Pharmacy designate PSE as a Schedule C-III controlled substance. This designation imposed a limit of 90 days supply for a prescription in the State of Oregon. It also requires that refills be filled within 180 days of prescription origin. The bill does not prohibit over-the-counter (OTC) sales, which continue to be subject to requirements of the CMEA. This bill affected 74 individuals in the TRICARE mail order pharmacy and 800 users in the retail point of service. Oregon patients receiving PSE products by prescription are now required to obtain a new prescription every six months.

As part of the review for this presentation, the PEC contacted eight Army and Navy MTFs to determine the regulatory impact on DoD OTC programs. Air Force policy prohibits OTC programs. Directors of four programs previously removed PSE off the drug list for OTC dispensing. Of facilities supplying PSE, all have QLs, require photo identification, and most require a signature. Navy policy requires entry of any of the drugs obtained from an OTC program into the patient's CHCS profile. Army policy does not require CHCS entries. Entry into the patient's CHCS profile would exceed the CMEA logbook requirement. Neither service has a program in place to meet the training requirements specified in the CMEA.

The P&T Committee agreed that there is little chance that large amounts of PSE could be diverted from MTF pharmacies. Mandatory logbook and training requirements are best addressed by the Pharmacy Service consultants/specialty leaders.

5. REVIEW OF RECENTLY APPROVED AGENTS

A. Recently Approved Agents in Classes Not Yet Reviewed for the UF

The P&T Committee was briefed on two new drugs, sitagliptin (Januvia) and paliperidone extended release [ER] tablets (Invega), which were approved by the FDA (see Appendix B). The P&T Committee determined that these two new drugs fall into drug classes that have not yet been reviewed for UF status; therefore, UF consideration was deferred until drug class reviews are completed.

B. Over-the-Counter Omeprazole Magnesium (Prilosec OTC)

Section 705 of the John Warner National Defense Authorization Act for Fiscal Year 2007 directs the Secretary of Defense to conduct a demonstration project under section 1092 of title 10, U.S. Code, to allow particular OTC drugs to be included on the UF under section 1074g of such title. For an OTC drug to be included as part of the OTC Demonstration Project, the P&T Committee must find that the OTC drug is cost effective and therapeutically equivalent to a prescription drug. Beneficiaries will be required to have a prescription for the OTC product.

OTC drugs provided under the demonstration project shall be made available through MTFs and the TRICARE mail order pharmacy. The demonstration will begin no later than 1 May 2007, and will last for a time period at least as long as the current contract, but no longer than five years.

Omeprazole magnesium is the first medication proposed for inclusion in the OTC Demonstration Project. Since this is the first opportunity for omeprazole magnesium to be considered for inclusion on the UF, it was reviewed as a new drug in a class already reviewed.

The P&T Committee previously reviewed the proton pump inhibitors (PPIs) in February 2005. These medications suppress secretion of gastric acid by irreversibly inhibiting H+, K+ ATPase (the proton pump) in gastric parietal cells. PPIs on the UF include prescription omeprazole (Prilosec, generics), rabeprazole (Aciphex), lansoprazole (Prevacid), and pantoprazole (Protonix). Esomeprazole (Nexium), the s-

isomer of omeprazole, is non-formulary under the UF. The BCF selections in this class are prescription omeprazole and rabeprazole.

1) *Relative Clinical Effectiveness* – Prescription omeprazole, first approved in 1987, is indicated for short-term treatment of active duodenal ulcer, benign gastric ulcer, and endoscopically-diagnosed erosive esophagitis; treatment of heartburn and other symptoms associated with gastroesophageal reflux disease; maintenance of healing of erosive esophagitis; long-term treatment of pathological hypersecretory conditions such as Zollinger-Ellison Syndrome; and for eradication of *H. pylori* infection (in combination with clarithromycin). Recommended doses range from 20 mg to 60 mg per day. It is available in 10-, 20-, and 40-mg delayed release capsules.

   Omeprazole magnesium was approved as an OTC medication in June 2002 based on placebo-controlled trials that found it to be effective in the treatment of recurring heartburn. It is labeled as a 14-day once-daily course of treatment for frequent heartburn (occurring two or more times per week), which may be repeated every four months. Each 20.6 mg delayed release tablet of omeprazole magnesium is equivalent to 20 mg of omeprazole. There is no reason to believe that the pharmacology or pharmacokinetics of omeprazole magnesium differ from prescription omeprazole.

   Common adverse events reported with the use of omeprazole magnesium include headache, diarrhea, and elevations in liver enzymes. Rare but severe adverse events include liver injury, bone marrow suppression, Stevens-Johnson syndrome, and hypersensitivity. Omeprazole magnesium is Pregnancy Category C. It is not recommended for patients under 18 years of age.

   Conclusion: The P&T Committee concluded that omeprazole magnesium has similar relative clinical effectiveness compared to other PPIs included on the UF. The P&T Committee also concluded that, while Food and Drug Administration (FDA)-approved indications differ for the OTC and prescription versions of omeprazole, there is no reason to believe that the clinical effect of omeprazole magnesium, when given to the same patients in the same doses, would differ from the anticipated effects of prescription omeprazole.

2) *Relative Cost Effectiveness* – The P&T Committee evaluated the relative cost effectiveness of in relation to efficacy, safety, tolerability, and clinical outcomes of the other agents in the PPI class. Information considered by the P&T Committee included, but was not limited to, sources of information listed in 32 CFR 199.21(e)(2).

   Based on the information reported from the relative clinical effectiveness evaluation, there was evidence to suggest that omeprazole magnesium has similar efficacy, safety, tolerability, and clinical outcomes compared to the existing drugs in the PPI class.

   The cost review for omeprazole magnesium compared the cost per unit across all three points of service to the other PPIs.

Conclusion: The results of the cost review showed that omeprazole magnesium is cost effective on a per unit basis when compared to generic prescription omeprazole in the mail order and MTF points of service. Omeprazole magnesium is more cost effective when compared to generic prescription omeprazole in the retail point of service. Omeprazole magnesium is more cost effective when compared to other products in the PPI class (i.e., esomeprazole, lansoprazole, pantoprazole, and rabeprazole) across all three points of service.

3) *Clinical and Cost effectiveness Conclusions* – The P&T Committee voted (13 for, 0 opposed, 2 abstained, 2 absent) to accept the clinical and cost effectiveness conclusions stated above.

   COMMITTEE ACTION – Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations, and other relevant factors, the P&T Committee, based upon its collective professional judgment, voted (13 for, 0 opposed, 2 abstained, 2 absent) to recommend that omeprazole magnesium be classified as formulary under the UF.

4) *MN Criteria* – Since omeprazole magnesium was not recommended for non-formulary status under the UF, establishment of MN criteria is not applicable.

5) *UF Implementation Period* – Since omeprazole magnesium was not recommended for non-formulary status under the UF, establishment of an implementation plan is not applicable.

6. DRUG CLASS REVIEW – NEWER SEDATIVE HYPNOTICS (SED-1s)

The P&T Committee evaluated the relative clinical effectiveness of the newer sedative hypnotic agents (SED-1s). The SED-1 drug class includes the following agents: zolpidem immediate release [IR] (Ambien), eszopiclone (Lunesta), ramelteon (Rozerem), zaleplon (Sonata), and zolpidem ER (Ambien CR).

All SED-1 agents except ramelteon are classified as benzodiazepine receptor agonists; they bind to benzodiazepine gamma-aminobutyric acid (GABA) receptors in the brain, but at a different site than the benzodiazepines. Ramelteon is mechanistically different; it acts as an agonist at melatonin receptors (MT_1 and MT_2) in the suprachiasmatic nucleus of the brain, which is responsible for regulation of the 24-hour sleep-wake cycle (circadian rhythm). All are FDA-indicated for the treatment of insomnia, although specific labeling differs.

The newer sedative hypnotics are preferred to benzodiazepines (the second most commonly used drug for insomnia) primarily due to a more favorable adverse effect profile and lower potential for abuse. They are widely used worldwide. Other medications for insomnia include sedating antidepressants such as trazodone, sedating antihistamines such as diphenhydramine, and other rarely used medications (e.g., chloral hydrate).

Utilization of the SED-1 agents is increasing rapidly in DoD. As of Dec 2006, about four million Military Health System (MHS) prescriptions for these agents are filled per month; the drug class was ranked #15 in terms of expenditures in FY 2006 ($111 million) – up from #18 in 2005 ($72 million), and #20 in 2004 ($54 million). Retail network

pharmacies dispense about three times more tablets than do MTFs and approximately five times more than mail order. Across the MHS, zolpidem IR is the most commonly prescribed SED-1, with about twice as many prescriptions compared to the next most commonly prescribed agent, zolpidem ER. Zolpidem ER is followed closely by eszopiclone. Usage of zaleplon is low and stable, while usage of the most recently introduced agent, ramelteon, is low but increasing. All of the SED-1 agents are brand-only; zolpidem IR is expected to become generically available in April 2007.

A. SED-1s – Relative Clinical Effectiveness

The P&T Committee evaluated the relative clinical effectiveness of the SED-1 agents currently marketed in the U.S. Information regarding the safety, effectiveness, and clinical outcomes of these drugs was considered. The clinical review included, but was not limited to, the requirements stated in the UF Rule, 32 CFR 199.21(e)(1). The P&T Committee was advised that there is a statutory presumption that pharmaceutical agents in a therapeutic class are clinically effective and should be included on the UF, unless the P&T Committee finds by a majority vote that a pharmaceutical agent does not have a significant, clinically meaningful therapeutic advantage in terms of safety, effectiveness, or clinical outcome over the other pharmaceutical agents included on the UF in that therapeutic class.

Insomnia is the most common sleep complaint across all stages of adulthood. Prevalence increases with age, from an estimated 10% of the younger adult population to up to 50% of elderly adults. Treatment includes both pharmacologic and non-pharmacologic approaches; however, non-pharmacologic treatments such as cognitive behavioral therapy are often not available to patients due to the need for extensive clinical contact. Patients should receive instruction on sleep hygiene measures (such as removing distractions from the sleeping area and avoiding stimulants at bedtime).

1) Efficacy

Many clinical trials compare the newer sedative hypnotic agents to placebo; some of these trials include an active comparator (most commonly zolpidem IR in addition to placebo. There are also many published trials comparing these agents to benzodiazepines. Two studies compare zolpidem IR to trazodone (Desyrel, generics), an antidepressant commonly used for insomnia.

In addition to measures of sleep onset and duration, the Committee also reviewed data assessing effect on quality of life, since the ultimate goal of treating insomnia is to improve overall health and well-being, not merely to increase the number of minutes spent asleep.

Based on this information, the P&T Committee came to the following conclusions:

- All SED-1 agents improve sleep latency (the amount of time it takes to fall asleep) compared to placebo, based on both polysomnographic measures (monitoring performed in a sleep lab) and subjective measures (as reported by patients). The amount of improvement compared to placebo appears similar among all of the agents. Data supporting the effect of ramelteon on sleep

latency appear to be the least robust, both in terms of the number of published studies and the amount of improvement demonstrated versus placebo. Published data with zolpidem ER are also limited, with a single published trial, but sleep latency data appear similar to the IR formulation and pharmacokinetic studies show little or no difference in initial drug concentrations.

- Zolpidem IR and eszopiclone appear to consistently improve total sleep time and awake time after sleep onset (or the amount of time spent awake after initially falling asleep) to a similar degree versus placebo. Zaleplon and ramelteon do not consistently demonstrate increases in measures of sleep duration.
- Zolpidem ER is a controlled release version of zolpidem consisting of a two-layer tablet providing an IR phase followed by a prolonged release phase. The formulation is intended to retain the onset and elimination characteristics of zolpidem IR while maintaining plasma concentrations three to six hours post-dose. Time versus concentration curves comparing zolpidem ER to zolpidem IR show comparable initial concentrations followed by higher concentrations of zolpidem ER during this time period. However, it is unclear whether this is associated with a clinically significant increase in sleep duration, as clinical trial data comparing zolpidem IR and ER are not available and reported effects on sleep duration with zolpidem ER do not appear markedly different from results from zolpidem IR trials.
- Trials including two or more SED-1 agents (usually compared to placebo) include three published trials comparing zaleplon and zolpidem IR to placebo and one unpublished trial obtained from the FDA statistical review of eszopiclone that included eszopiclone and zolpidem IR. Based on these trials, zaleplon decreased sleep latency to a greater degree than zolpidem IR (8-24 minutes for zaleplon versus 6-13 minutes for zolpidem IR, but zolpidem IR increased total sleep time more than zaleplon (28-42 minutes for zolpidem IR versus 7-27 minutes for zaleplon). More rebound insomnia was noted with zolpidem IR on the first night after discontinuation. The FDA statistical review for eszopiclone reported very similar results for eszopiclone versus zolpidem IR with respect to sleep latency, total sleep time, and awake time after sleep onset.
- Based on trials comparing zolpidem IR and zopiclone (eszopiclone's racemic parent drug) to benzodiazepines, the newer sedative hypnotics appear to be similar in efficacy to the benzodiazepines. Short-term adverse events appear similar based on published trials; however, there appears to be more rebound insomnia with benzodiazepines than with the newer sedative hypnotics.
- A single comparative trial of zolpidem IR versus trazodone in adult insomnia sufferers without co-morbid depression demonstrated similar efficacy during the two weeks of the study; although trazodone may result in greater daytime somnolence than zolpidem IR.

- In regard to improvement of sleep architecture, there are no consistent data to demonstrate that the newer sedative hypnotics increase the length of time spent in the stages of sleep associated with restorative sleep to a degree that is clinically significant, compared to placebo.
- The most extensive data supporting long-term efficacy and safety are for eszopiclone, which has data from a 6-month randomized controlled trial (RCT) and open label data out to one year. Zolpidem IR has data from RCTs indicating continued efficacy and safety over 35 nights of nightly use and 84 nights of non-nightly use, with open label data out to one year. No long-term data are available for zolpidem ER, which was only tested in short-term trials (three weeks), although it is probably reasonable to expect long-term results similar to zolpidem IR (Ambien). Zaleplon RCT data are limited to 4-week trials, although open label data supporting efficacy and safety for up to one year are available in elderly patients. Ramelteon has shown sustained efficacy and safety for up to five weeks in RCTs, with open label data out to one year.
- Improvement in overall quality of life as a function of improved sleep was not usually addressed in either short- or long-term clinical trials. However, a few trials employed quality of life assessment tools, with one of the most useful measures being the standardized short-form 36 (SF-36) questionnaire. Two non-nightly zolpidem IR studies demonstrated a minimal improvement on certain aspects of the SF-36 after treatment, but no difference from placebo on other aspects. Two eszopiclone studies that included pre and post-treatment questionnaires addressing improvement in overall sense of well-being showed no significant improvement versus placebo. The Committee concluded that there is insufficient evidence to conclude that SED-1 agents have a major beneficial effect on quality of life, although there limited are data showing improvement in certain aspects of quality of life. There are insufficient comparative data to draw conclusions about individual agents.

2) Safety / Tolerability

- The SED-1 agents, including both the benzodiazepine receptor agonists and ramelteon, appear to have similar adverse effect profiles, most commonly drowsiness, dizziness, and headache. Rates of discontinuation due to adverse events during clinical trials were similar among the SED-1 agents, ranging from about 2-6% in short-term trials. Adverse effects and discontinuation rates due to adverse events were similar in comparative trials (zolpidem IR versus zaleplon; eszopiclone versus zolpidem IR). An unpleasant taste was consistently reported with eszopiclone during clinical trials, occurring in about 26.1% of patients receiving eszopiclone versus 5.6% with placebo over the course of a 6-month trial.
- Daytime sleepiness, impairments in psychomotor function and cognitive function, adverse effects on driving safety, and increased risk for falls may occur with any of the benzodiazepine receptor agonists; there are little or no data for the melatonin receptor agonist ramelteon. Agents with longer elimination half-lives tend to pose a greater risk for these effects. Particularly

notable is the 6-hour half-life of eszopiclone, which may extend to nine hours in elderly patients, compared to half-lives of about one hour for zaleplon, 1-2.6 hours for ramelteon and 2.5-2.8 hours for zolpidem (Ambien, Ambien CR). Lower starting doses of all SED-1 agents except ramelteon are recommended in elderly patients.

- Driving safety studies report impaired performance and increased risk of accidents with eszopiclone's racemic parent drug zopiclone (widely used outside the U.S.) at a 7.5 mg daily dose. The applicability of these data to eszopiclone is unclear, since the usual younger and elderly adult dosing strengths of eszopiclone (3 and 2 mg, respectively) would be equivalent to zopiclone doses lower than 7.5 mg. Product labeling and marketing for eszopiclone advises against taking the product unless the patient is able to get eight or more hours of sleep; adherence to this warning is advisable. There was no reported difference between eszopiclone and zolpidem IR on subjective measures of next day effects (morning sleepiness, daytime alertness, daytime ability to function), based on results of one unpublished trial reported in the FDA statistical review of eszopiclone.
- Because of its very short half-life, a repeat dose of zaleplon may be taken after the patient has had difficulty falling asleep, as long as the patient is able to sleep for four or more hours. Driving studies with zaleplon 10 and 20 mg showed no significant effects on morning driving even after middle-of-the-night administration. Since the risk of falling and hip fracture tend overall to increase with increasing half-life, zaleplon may have an advantage in elderly patients. However, this is not a simple relationship and prescribers must take into account patient activity patterns; short half-life agents may be more likely to cause falls during the early part of the night.
- In other special patient populations, it is difficult to see major advantages or disadvantages for any one agent. All are hepatically metabolized and carry warnings about use and/or recommendations for dose adjustment in patients with hepatic dysfunction; pharmacokinetic parameters do not appear to be substantially affected by renal dysfunction. All are Pregnancy Category C. Little data is available concerning use in pediatric patients; there is some concern about chronic or chronic intermittent use of ramelteon in pediatric patients due to effects on prolactin and testosterone levels that are not felt to be clinically significant in adults.
- The most prominent withdrawal symptom upon discontinuation of the SED-1 agents is probably rebound insomnia, or worsening of insomnia compared to the patient's pre-treatment baseline; other withdrawal symptoms may also occur. Rebound insomnia typically occurs only in the first night after discontinuation. Occurrence of rebound insomnia has been reported in clinical trials with all of the SED-1 agents except ramelteon. Based on three trials, more rebound insomnia on the first night after discontinuation was noted with zolpidem IR versus zaleplon.

- All of the newer sedative hypnotics, with the exception of ramelteon, probably have a small, but significant potential for abuse, although this is likely to be rare in patients without psychiatric disorders or previous history of substance abuse. Ramelteon appears to lack significant abuse potential and may be preferable in patients with a high risk of substance abuse. Ramelteon is the only agent in this class that is not a DEA scheduled substance.
- No major comparative disadvantages were noted among the agents based on potential for drug-drug interactions. All are affected by potent CYP 3A4 inducers or inhibitors and have predictable additive effects if given with alcohol or other medications that can impair psychomotor performance. Cimetidine (Tagamet, generics) markedly increases levels of zaleplon due to inhibition of two metabolic pathways (CYP 3A4 and aldehyde oxidase); the initial dose of zaleplon should be decreased. The major metabolic route for ramelteon is CYP 1A2; ramelteon is contraindicated with the potent 1A2 inhibitor fluvoxamine (Luvox, generics) and may be less effective in smokers, since smoking is a 1A2 inducer.

3) Other Uses

Based on its effects on the sleep-wake cycle, ramelteon may have a niche in therapy for time zone shifting in travelers, or for phase shifting in shift workers, but data at this point are limited.

4) Provider Opinion

A total of 173 DoD healthcare providers responded to a survey regarding the SED-1 agents; 72% of responders were physicians, 22% pharmacists, 5% physician assistants or advanced practice nurses, and 1% other. The most common specialties were psychiatry (25%), pharmacists (22%), and family practice, internal medicine, or general practice (21%). The vast majority of responders (97%) indicated that they had zolpidem IR on their local formulary, but relatively few indicated that other SED-1 agents were on formulary (zolpidem ER 18%, ramelteon 3%, eszopiclone and zaleplon 0%).

The majority of responders estimated that between 40 and 79% of patients could be successfully treated with their first choice of agents. Most (71%) would treat patients failing the first agent with another SED-1 agent; the majority estimated that between 20 and 59% of patients could be successfully treated with the second agent. The majority of responders estimated that fewer than 20% of patients discontinue therapy due to adverse events.

5) Clinical Effectiveness Conclusion

The P&T Committee concluded that:

a) Based on placebo-controlled trials, all SED-1 agents decrease sleep latency to a similar degree. Data supporting the effect of ramelteon on sleep latency appear to be the least robust, both in terms of the number of published studies and the amount of improvement demonstrated versus placebo. Zolpidem IR and eszopiclone have evidence indicating consistent and similar increases in

sleep duration. Zaleplon and ramelteon do not appear to consistently increase sleep duration.

b) Based on three comparative trials, zaleplon appears to decrease sleep latency more than zolpidem IR, but zolpidem IR appears to increase total sleep time more than zaleplon. In one comparative trial, very similar results were reported for eszopiclone versus zolpidem IR with respect to measures of sleep latency and sleep duration.

c) Based on comparative trials, SED-1 agents appear to be similar in efficacy and short-term adverse events, compared to benzodiazepines; benzodiazepines may cause more rebound insomnia. Zolpidem IR appears to be similar in efficacy to the sedating antidepressant trazodone, based on one comparative trial in non-depressed patients; trazodone may result in greater daytime somnolence.

d) There are no consistent data to demonstrate that SED-1 agents have beneficial effects on sleep architecture, compared to placebo.

e) There is insufficient evidence to conclude that SED-1 agents have a major beneficial effect on quality of life, although limited data show improvement in certain domains of the SF-36. There are insufficient comparative data to draw conclusions about individual agents.

f) The SED-1 agents appear to have similar adverse effect profiles and to result in similar rates of discontinuation due to adverse events in clinical trials. Eszopiclone is associated with an unpleasant taste. There do not appear to be any major disadvantages for any one agent with respect to drug-drug interactions. Ramelteon may be less effective in smokers.

g) Daytime sleepiness, impairments in psychomotor function and cognitive function, adverse effects on driving safety, and increased risk for falls may occur with any of the benzodiazepine receptor agonists; there are little or no data for the melatonin receptor agonist ramelteon. Agents with longer half-lives tend to pose a greater risk for these effects. The SED-1 agent with the longest half-life is eszopiclone, six hours (up to nine hours in elderly patients); followed by zolpidem (Ambien, Ambien CR), 2.5-2.8 hours; ramelteon, 1-2.6 hours; and zaleplon, one hour. Lower starting doses of all SED-1 agents except ramelteon are recommended in elderly patients.

h) The applicability of driving safety studies reporting impaired performance and increased risk of accidents with a 7.5 mg dose of zopiclone (eszopiclone's racemic parent drug) is unclear, since recommended doses of eszopiclone would be equivalent to zopiclone doses lower than 7.5 mg. There was no reported difference between eszopiclone and zolpidem IR on subjective measures of next day effects based on results of an unpublished trial reported in the FDA statistical review of eszopiclone.

i) Because of its very short half-life, zaleplon may be taken in the middle of the night after a patient has had difficulty falling asleep without demonstrating adverse effects on driving performance the next morning. It may have an

advantage in elderly patients, since risk of falls and hip fracture tends overall to increase with increasing half-life (although the relationship between falls and half-life is not straightforward and prescribers must take into account patient activity patterns).

j) No SED-1 agent appears preferable in other special patient populations (hepatic or renal dysfunction, pregnancy, pediatrics); there is some concern about use of ramelteon in pediatric patients due to possible endocrine effects.

k) Rebound insomnia has been reported in clinical trials with all SED-1 agents except ramelteon; more rebound insomnia was noted with zolpidem IR than with zaleplon during comparative trials.

l) All SED-1 agents, with the exception of ramelteon, probably have a small but significant potential for abuse. Ramelteon appears to lack significant abuse potential and may be preferable in patients at high risk for substance abuse. Ramelteon is the only SED-1 agent that is not a DEA scheduled substance.

m) It is likely that at least two SED-1 agents are needed for adequate clinical coverage, based on provider responses regarding prescribing practices and likely patient response.

COMMITTEE ACTION: The P&T Committee voted (15 for, 0 opposed, 1 abstained, 0 absent) to accept the clinical effectiveness conclusions stated above.

B. SED-1s – Relative Cost Effectiveness

In considering the relative cost effectiveness of agents within this class, the P&T Committee evaluated the costs of the agents in relation to the efficacy, safety, tolerability, and clinical outcomes of the other agents in the class. Information considered by the P&T Committee included but was not limited to sources of information listed in 32 CFR 199.21(e)(2). Given the overall clinical conclusion that the agents within the SED-1 class have similar relative clinical effectiveness, a cost-minimization analysis (CMA) was employed to assess the relative cost effectiveness of the agents within this therapeutic class. The agents were evaluated on their weighted average cost per day of therapy across all three points of service.

The CMA for the SED-1 class revealed the following cost effectiveness rank-order (from most to least cost effective): 1) eszopiclone; 2) ramelteon; 3) zaleplon; 4) zolpidem IR; and 5) zolpidem ER. Although zolpidem IR was not as cost effective as eszopiclone in this CMA, the P&T Committee noted that zolpidem IR is scheduled to become generically available on 21 April 2007 and will likely become the most cost effective agent within the class shortly thereafter.

A budget impact analysis (BIA) of various UF formulary scenarios was conducted to estimate the influence of other factors associated with a UF decision (i.e., market share migration, switch costs, and non-formulary cost-shares). The goal of the BIA was to aid the P&T Committee in determining which group of SED-1 agents best met the majority of the clinical needs of the DOD population at the lowest expected cost to the MHS.

The BIA also considered the cost effectiveness of implementing a prior authorization (PA) that requires a trial of zolpidem IR for patients starting treatment with a SED-1 agent. This PA would incorporate the automated PA capability in PDTS in order to "look-back" at the patient's profile during the last 180 days. Based on this automated review, TRICARE would cover prescriptions for a SED-1 agent other than zolpidem IR if the patient had received a prescription for any SED-1 agent (including zolpidem IR) at any MHS pharmacy point of service (MTFs, retail network pharmacies, or mail order) during this previous 180 days. Patients who had not received a SED-1 agent prescription during the last 180 days would be required to meet PA criteria for any SED-1 agent other than zolpidem IR (Ambien). (See Appendix D.)

Cost Effectiveness Conclusion

The P&T Committee concluded that:

1) Eszopiclone was the most cost effective agent until zolpidem IR becomes generically available with competitive pricing.
2) Ramelteon, zaleplon, and zolpidem ER were more costly than eszopiclone and provided no meaningful clinical therapeutic advantage compared to eszopiclone or zolpidem IR.
3) The UF scenario utilizing a prior authorization requiring a trial of zolpidem IR by new SED-1 patients was more cost effective relative to UF scenarios not requiring a trial of zolpidem IR by new SED-1 patients.

COMMITTEE ACTION: The P&T Committee voted (15 for, 0 opposed, 1 abstained, 1 absent) to accept the cost effectiveness conclusion stated above.

C. SED-1s – UF Recommendations

COMMITTEE ACTION: Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of the SED-1 agents, and other relevant factors, the P&T Committee, based upon its collective professional judgment, voted (13 for, 1 opposed, 2 abstained, 1 absent) to recommend that: 1) zolpidem IR and eszopiclone be maintained as formulary on the UF with a prior authorization requiring a trial of zolpidem IR for new patients and 2) that ramelteon, zaleplon, and zolpidem ER be classified as non-formulary under the UF with a PA requiring a trial of zolpidem IR for new patients.

The P&T Committee agreed that the following PA criteria should apply to SED-1 agents other than zolpidem IR. Coverage would be approved if a patient met any of the following criteria:

1) Automated PA criteria:

   The patient has received a prescription for any SED-1 agent (including zolpidem IR) at any MHS pharmacy point of service (MTFs, retail network pharmacies, or mail order) during the previous 180 days.

2) PA criteria if automated criteria are not met:

   The patient has tried zolpidem IR and had an inadequate response or was unable to tolerate it due to adverse effects.

Treatment with zolpidem IR is contraindicated.

The P&T Committee noted that in order for a patient to receive a non formulary SED-1 agent at the formulary cost-share, both the PA and MN criteria must be met. If the PA criteria are met without an approved MN determination, the patient cost-share will be at the non-formulary level. In other words, patients obtaining an approved PA for ramelteon, zaleplon, or zolpidem ER would NOT automatically receive it at the formulary cost-share.

The P&T Committee also noted that the PA is not intended to apply where there are existing policies and protocols in place for operational/readiness situations and that MTFs should make necessary allowances for such use.

D. SED-1s – MN Criteria

Based on the clinical evaluation for ramelteon, zaleplon, and zolpidem ER, and the conditions for establishing medical necessity for a non-formulary medication provided for in the UF rule, the P&T Committee recommended the following general MN criteria for ramelteon, zaleplon, and zolpidem ER:

1) Use of formulary alternatives is contraindicated.
2) The patient has experienced or is likely to experience significant adverse effects from formulary alternatives.
3) Use of formulary alternatives has resulted in therapeutic failure.

The P&T Committee noted that while zolpidem IR and eszopiclone would both be considered formulary alternatives, a trial of zolpidem IR would be required for patients who had not received a SED-1 prescription in the last 180 days at an MHS pharmacy point of service (MTFs, retail network pharmacies, or mail order).

COMMITTEE ACTION: The P&T Committee voted (15 for, 0 opposed, 1 abstained, 1 absent) to approve the MN criteria outlined above.

E. SED-1s – UF Implementation Period

Approximately 40,447 patients (21% of all SED-1 patients) would be affected by the recommended non-formulary selections in this drug class. This figure includes both patients who have previously received SED-1 agents, as well as new users starting on SED-1 agents. Based on the number of new users and the current percentage of new users receiving SED-1 agents other than zolpidem IR in retail (50%) and mail (40%), the prior authorization for SED-1 agents other than zolpidem IR would affect approximately 12,500 users per quarter, or 50,000 annually.

The P&T Committee noted that this would be the first time a PA including the newly available automated review process had been established in a class also including non-formulary agents and that many operational details of the process had yet to be worked out. Accordingly, the P&T Committee voted to recommend an implementation period of the greater of 1) the first Wednesday following a 90-day implementation period or 2) the time necessary to complete logistical arrangements to implement the automated PA.

MTFs will not be allowed to have ramelteon, zaleplon, or zolpidem ER on their local formularies. MTFs will be able to fill non-formulary requests for these agents only if both of the following conditions are met: 1) the prescription must be written by a MTF provider, and 2) MN is established. MTFs may (but are not required to) fill a prescription for a non-formulary SED-1 agent written by a non-MTF provider to whom the patient was referred, as long as MN has been established.

COMMITTEE ACTION: The P&T Committee voted (14 for, 0 opposed, 2 abstained, 1 absent) to recommend an implementation period of the greater of 1) the first Wednesday following 90 day implementation period or 2) the time necessary to complete logistical arrangements to implement the automated PA.

F. SED-1s – BCF Review and Recommendations

The P&T Committee considered the BCF status of the SED-1 Agents. Currently there are no SED-1 agents on the BCF; the P&T Committee had previously determined at the August 2006 meeting that at least one SED-1 agent would be placed on the BCF. Zolpidem IR is widely used at MTFs, has clinical data supporting efficacy both for decreasing sleep latency and increasing sleep duration, is clinically similar to other SED-1 agents with respect to safety and tolerability, and is expected to become the most cost effective SED-1 agent after it becomes generically available (anticipated date: 21 April 2007). The P&T Committee agreed that zolpidem IR should be placed on the BCF.

COMMITTEE ACTION: The P&T Committee voted (13 for, 0 opposed, 3 abstained, 1 absent) to recommend adding zolpidem IR as the BCF selection in this class.

7. DRUG CLASS REVIEW – NARCOTIC ANALGESICS

The drugs in this class comprise all narcotic analgesics (also referred to as opioids or opiate agonists) used for the treatment of pain on an outpatient basis, including combinations with acetaminophen (APAP), aspirin (ASA), and other non-opioids. Not included in this drug class review are narcotic analgesics given primarily by intravenous injection or infusion, over-the-counter products, products requiring administration by a medical professional, products in which the narcotic component is primarily used as an antitussive, and products indicated solely for the treatment of opioid dependence.

For review purposes, the narcotic analgesics were divided into the following categories, based on their potency (as reflected by their DEA status) and whether or not they are combined with a non-opioid analgesic, as outlined in Table 1. These categories do not take into account all differences among agents, but serve to reduce the large number of available agents into manageable categories. Most of these agents are now generically available.

The narcotic analgesics accounted for approximately $153 million dollars in MHS expenditures in FY 2006 and are ranked #8 in terms of total expenditures during that time period. Approximately 437,000 DoD beneficiaries received one or more prescriptions for a narcotic analgesic during FY 2006.

By category, the majority of MHS narcotic analgesic prescriptions during FY 2006 (59%) were for the lower potency opioid combinations, which are widely prescribed following

Table 1: Narcotic Analgesic Categories & BCF Listings as of Feb 2007

Category	Medications	BCF Agents (Feb 07)
High potency Opioids (Schedule II Agents) – Single Analgesic Ingredient	▪ Codeine* - tablets, solution, injection ▪ **Fentanyl** – transdermal (Duragesic), transmucosal lozenges (Actiq), buccal tablets (Fentora) ▪ Hydromorphone – injection, tablets, liquid ▪ Levorphanol – tablets, injection ▪ Meperidine – tablets, solution, injection ▪ Meperidine / promethazine – capsules ▪ Methadone – oral concentrate, solution, tablet, injection ▪ **Morphine –** IR tablets, 12-hr ER tablets (MS Contin, generics; Oramorph SR), 24-hr ER capsules (Avinza, Kadian), solution, suppositories, injection ▪ Opium - tincture; opium / belladonna alkaloids – suppositories ▪ **Oxycodone –** IR capsules, oral concentrate, solution, 12-hr ER tablets (Oxycontin), IR tablets ▪ Oxymorphone – IR tablets (Opana); 12-hr ER tablets (Opana ER)	Morphine sulfate 15 mg, 30 mg and 60 mg 12-hour extended release tablets (MS Contin, generics; excludes 100 and 200 mg strengths)
High potency (Strong) Opioids (Schedule II Agents) – Analgesic Combos	▪ **Oxycodone/** APAP – tablets, capsules, solution ▪ Oxycodone / ASA – tablets	Oxycodone 5 mg/APAP 325 mg and/or 500 mg oral
Lower-Potency (Mild) Opioids (Schedule III, IV, V & Non-Controlled Agents) – Single Analgesic Ingredient Agents	▪ Buprenorphine – injection (sublingual tablets not included in class) ▪ Butorphanol – nasal spray, injection ▪ Pentazocine / naloxone – tablets ▪ Propoxyphene – capsules, tablets ▪ Nalbuphine (not controlled) – injection ▪ **Tramadol** (not controlled) **–** IR tablet, 24-hr ER tablets (Ultram ER)	None
Lower-Potency (Mild) Opioids (Schedule III, IV, V & Non-Controlled Agents) – Analgesic Combos	▪ **Codeine / APAP –** tablets, elixir, oral suspension ▪ Codeine / ASA – tablets ▪ Codeine / ASA / carisoprodol - tablets ▪ Codeine / caffeine / butalbital / APAP – capsules ▪ Codeine / caffeine / butalbital / ASA – capsules ▪ Dihydrocodeine / caffeine / APAP – capsules, tablets ▪ Dihydrocodeine / caffeine / ASA – capsules ▪ **Hydrocodone / APAP** – capsules, solution, tablets ▪ Pentazocine / APAP – tablets ▪ **Propoxyphene / APAP** – tablets ▪ Propoxyphene / ASA / caffeine – capsule ▪ **Tramadol / APAP** (not controlled) – tablets	Codeine/APAP oral

* Pharmacologically and therapeutically, codeine is usually referred to as a weak opioid; however, single ingredient codeine formulations are classified by the DEA as Schedule II medications (C-IIs) and are so classified in this table. The most commonly used medications are bolded.
APAP = acetaminophen; ASA = aspirin; ER = extended release; IR = immediate release

injuries or medical / dental procedures; followed by high potency opioid combos (19%); high potency single analgesic products (13%); and lower potency opioid single analgesic products (9%). The majority of expenditures during this time period, however, were for the high potency single analgesic products (67%), followed by the lower-potency opioid combinations (20%), the high potency opioid combinations (8%), and the lower-potency single analgesic products (5%). This reflects the relatively higher cost and more intensive treatment regimens associated with the high potency single analgesic products used for chronic treatment of pain, some of which are still brand-only medications.

Pharmacologically, the narcotic analgesics act at opioid receptors (mu, kappa, and delta), inhibiting excitatory neurotransmission of substance P, acetylcholine, norepinephrine, dopamine, and GABA by blocking voltage-dependent calcium channels. Analgesia is mediated through changes in the perception of pain at the spinal cord (mu_2, delta, kappa receptors) and higher levels in the central nervous system (CNS) (mu_1 and kappa

receptors). Narcotic analgesics also have effects on the endocrine and immune systems. Stimulation at the mu receptor produces euphoria, respiratory depression, and physical dependence. In addition to acting at mu receptors, tramadol is also a weak inhibitor of norepinephrine and serotonin reuptake, resulting in inhibition of pain transmission in the spinal cord (similar to monoamine oxidase inhibitors [MAOIs] or tricyclic antidepressants [TCAs]).

Narcotic analgesics are primarily indicated for the treatment of mild, moderate and severe pain. Use correlates with potency, with the higher potency agents (e.g., morphine, oxycodone, fentanyl) used in more severe pain and lower potency agents and combinations with non-opioids used for less severe pain. Some narcotic analgesics have specific clinical niches:

- Opium is used in combination with the anticholinergic belladonna for the treatment of pain caused by ureteral spasm; more effective and/or safer agents have largely replaced the use of opium tincture for diarrhea.
- Use of meperidine, a short-acting narcotic analgesic primarily given parenterally due to poor oral absorption, is limited to acute pain situations due to a neurotoxic metabolite that can cause anxiety, tremors, myoclonus, and generalized seizures with repetitive dosing.
- Methadone is used for detoxification and maintenance treatment of narcotic addiction, but also for chronic pain.
- The nasal formulation of butorphanol is used primarily for migraine headache; this product was initially released as a non-scheduled product, but was subsequently scheduled as a C-IV controlled substance following multiple reports of abuse.
- Tramadol has a lower potential for abuse or respiratory depression than other narcotic analgesics, lacks significant cardiac effects, and is not associated with peptic ulcer disease, making it an alternative in patients who cannot tolerate non-steroidal anti-inflammatory drugs (NSAIDs). Due to its dual mechanism of action, tramadol may have a more prominent place in the treatment of neuropathic pain than other narcotic analgesics.

The majority of the narcotic analgesics are IR and/or short-acting medications most commonly used on an every four to six hour basis. Longer duration products include fentanyl transdermal patches (Duragesic, generics), which are applied every 72 hours; morphine, which is available in 12-hour (MS Contin, generics; Oramorph SR) and 24-hour ER formulations (Avinza, Kadian); oxycodone, which is available in a 12-hour ER formulation (Oxycontin); oxymorphone, which was recently approved as a 12-hour ER formulation (Opana ER), tramadol, which is available in a once daily ER formulation (Ultram ER), and methadone, which may be dosed less frequently when given chronically, due to a depot effect. Levorphanol has a long half-life and an extended duration of action (four to eight hours), but its use is limited by sedation and concerns about drug accumulation.

Pure opiate agonists may be categorized by their chemical structure as phenanthrenes (codeine, hydromorphone, morphine, and oxycodone; phenylpiperidines (fentanyl, meperidine); or diphenylheptanes (methadone, propoxyphene). They are therapeutically

classified as either strong opiates (hydromorphone, morphine, methadone, and oxycodone) or weak opiates (codeine, hydrocodone, and propoxyphene). Use of mixed agonist antagonists (e.g., buprenorphine, nalbuphine, butorphanol, and pentazocine) is limited by ceiling analgesia effects and the risk of inducing withdrawal symptoms and recurrence of pain in patients taking chronic opioids.

Tolerance to the adverse effects of narcotic analgesics, including respiratory depression, occurs with chronic use. Tolerance to therapeutic effects requiring dose escalation also occurs; some patients may require very large doses of narcotic analgesics to control their pain. Patients often require changes in chronic opioid therapy to address adverse effects or lack of efficacy; switching or rotating different opioids (opioid rotation) has been proposed as a strategy to obtain optimal pain control with minimum adverse effects.

Combination products including both a narcotic analgesic and non-opioid analgesic (most commonly acetaminophen) provide additive analgesic effects, but also limit the possible dose of the narcotic analgesic due to potential toxicity and dosing limits associated with the non-opioid component (e.g., no more than 4 grams of acetaminophen daily). They are not well suited for the treatment of chronic pain.

Standard tables of equianalgesic doses are available to assist clinicians in safely switching between long-acting opioids, typically by converting the total 24-hour dose to an equivalent amount of morphine and from there to the appropriate 24-hour dose of the new opioid. This process is complicated by wide intra-patient variability in response and incomplete cross-tolerance among opioids; for this reason, recommended conversions are usually conservative and titration of the new opioid is likely to be required. Disparate methodologies in calculating equianalgesic doses for transdermal fentanyl, levorphanol and methadone exist; these agents may be more difficult to titrate than other narcotic analgesics.

A. Narcotic Analgesics – Relative Clinical Effectiveness

The P&T Committee evaluated the relative clinical effectiveness of the narcotic analgesics class. Narcotic analgesics were divided into the categories outlined in Table 1, based on DEA schedule, potency, and whether or not the analgesic is a combination agent. Information regarding the safety, effectiveness, and clinical outcomes of these drugs was considered. The clinical review included, but was not limited to, the requirements stated in the UF Rule, 32 CFR 199.21(e)(1). The P&T Committee was advised that there is a statutory presumption that pharmaceutical agents in a therapeutic class are clinically effective and should be included on the UF, unless the P&T Committee finds by a majority vote that a pharmaceutical agent does not have a significant, clinically meaningful therapeutic advantage in terms of safety, effectiveness, or clinical outcome over the other pharmaceutical agents included on the UF in that therapeutic class.

The clinical efficacy review was divided into two major areas: chronic pain (cancer, non-cancer, or neuropathic) and acute pain (post-operative or non-specific). Because ample information is available for most of these agents, the review focused primarily on published meta-analyses, systematic reviews, and well-accepted tertiary literature sources, including clinical practice guidelines. A more detailed review of the literature was performed for specific issues affecting potential formulary decisions.

No single systematic review, meta-analysis, or clinical practice guideline addresses the use of narcotic analgesics to treat all types of chronic and acute pain. Sources included:

- *Chronic cancer pain* – Available cancer pain studies are in general too heterogeneous to conduct systematic reviews. The review included applicable conclusions from a 2001 Agency for Healthcare Research and Quality (AHRQ) technical report, a meta-analysis of four evaluable trials comparing long-acting oxycodone to morphine and hydromorphone [Reid *et al.*, 2006], and head-to-head trials and data analyses comparing two or more narcotic analgesics published since the AHRQ report. Sources of clinical practice guidelines for the treatment of cancer pain include the World Health Organization, the American Pain Society, and the University of Texas MD Anderson Cancer Center.
- *Chronic non-cancer pain* – The most useful reference for the treatment of chronic non-cancer pain was the Drug Effectiveness Review Project (DERP) review of long-acting opioid analgesics for non-cancer pain, last updated July 2006 [Chou *et al.*, 2006]. This review included all drugs reviewed here except for hydrocodone, levorphanol, and the agonist-antagonist agents. In addition, the review included a meta-analysis [Furlan *et al.*, 2006] comparing "weak" opioids (tramadol, propoxyphene, codeine) and "strong" opioids (morphine, oxycodone) to other agents in chronic pain patients primarily suffering from chronic non-cancer pain (osteoarthritis, rheumatoid arthritis, or low back pain), as well as clinical trials assessing the efficacy of the two available fentanyl formulations for breakthrough pain (buccal tablets and transmucosal lozenges). Sources of clinical practice guidelines for the treatment of chronic non-cancer pain included the American Society of Interventional Pain and VA/DoD.
- *Chronic neuropathic pain* – Clinical evidence specifically addressing the use of narcotic analgesics in chronic neuropathic pain is limited; the most useful review was considered to be the one conducted by Finnerup *et al.* (2005) in an attempt to construct an evidence-based algorithm for the treatment of neuropathic pain. The review also included a meta-analysis of trials assessing the efficacy of morphine, methadone, and oxycodone for neuropathic pain and published treatment recommendations from an expert panel group.
- *Acute pain* – There is little literature addressing the use of narcotic analgesics for non-specific acute pain. Consensus statements from the American Pain Society and the American Society for Pain Management Nursing support the appropriate use of "as needed" dosage range orders for narcotic analgesics in the treatment of acute pain. With respect to postoperative pain, the review relied heavily on the Bandolier Oxford League Table of Analgesic Efficacy, which is based on data compiled from single-dose studies in patients with moderate to severe pain. The review also provided clinical trial data or the results of Cochrane reviews for agents not included in the League table and recommendations from the VA/DoD Clinical Practice Guideline for the Management of Postoperative Pain.

1) Efficacy

a) Chronic pain

The clinical review divided chronic pain into three types, based on etiology: cancer pain, non-cancer pain, and neuropathic pain (considered separately from other causes of non-cancer chronic pain).

Treatment algorithms for chronic cancer pain typically start with non-opioids (e.g., NSAIDs, acetaminophen); progress to weak opioids such as codeine or hydrocodone, normally in combination with the non-opioid (some algorithms skip this step depending on pain severity); and then progress to around-the-clock treatment with long-acting high potency single analgesic agents plus IR opioids for breakthrough pain.

There is less consensus about the use of chronic opioids in patients with non-cancer pain (e.g., low back pain, rheumatoid arthritis, osteoarthritis), although various professional organizations have endorsed judicious use of opioids in patients with refractory chronic non-cancer pain. Recommended treatment algorithms are similar to chronic cancer pain.

The categories of drugs most pertinent to treatment of chronic pain are likely the high potency long-acting agents used on an around-the-clock basis for the treatment of constant pain, and the high potency IR agents, which are used for the treatment of breakthrough pain occurring despite treatment with long-acting agents. The most commonly used medications are long-acting and IR formulations of morphine, oxycodone, and fentanyl.

The placement of narcotic analgesics in treatment guidelines for neuropathic pain appears controversial; discussion of the topic is complicated by the fact that some authors consider tramadol to be an opioid and some do not. In general, narcotic analgesics are regarded as third-line agents after TCAs and gabapentin/pregabalin, although at least one set of treatment recommendations lists them among other agents as potential first-line choices.

iii) Clinical evidence in constant cancer pain

Available cancer pain studies are in general too heterogeneous to conduct systematic reviews and many are small and of poor quality. The 2001 AHRQ technical report provided an extensive review of cancer pain literature that served to highlight the limited data available. Out of nine trials, one reported oxycodone to be less effective than morphine, but equally or more often preferred by patients; one reported tramadol to be similar to morphine in efficacy and patient preference (nurses thought pain control was better with morphine but tramadol more tolerable); two reported methadone to be as effective as morphine; one reported buprenorphine as effective as morphine; and one reported propoxyphene to be more effective than low-dose morphine. Eight studies comparing sustained (12-hour formulations) and IR morphine found no difference in efficacy.

Head-to-head comparative trials, one meta-analysis, and a pooled analysis of transdermal fentanyl data published since the AHRQ report add little additional information. A meta-analysis of four randomized double-blind controlled trials found no differences in mean pain scores between oxycodone and either morphine or hydromorphone. An open-label trial comparing transdermal fentanyl to sustained release (every 12-hour) morphine found no differences in efficacy; the percentage of patients reporting constipation and withdrawals due to adverse effects favored transdermal fentanyl. A pooled analysis of transdermal fentanyl data reported similar results, with withdrawals due to adverse effects of 16% with transdermal fentanyl versus 23% with morphine ($p<0.001$). A 4-week trial comparing methadone and morphine reported similar efficacy, but a higher withdrawal rate with methadone (22% versus 6%, $p=0.019$). Two open-label crossover trials involving oxymorphone (Opana ER) versus morphine or oxycodone sustained release reported similar efficacy and concluded that patients could safely be switched from these medications to ER oxymorphone.

The 24-hour ER morphine products (Avinza and Kadian) are purported to have distinct advantages compared to 12-hour ER morphine products, including continuous pain relief, reduced sleep disturbance, ease of use, and fewer reported side effects. These benefits have not been shown to be statistically or clinically significant based on head-to-head trials with 12-hour ER morphine. Trials comparing Kadian or Avinza to 12-hour ER morphine have demonstrated bioequivalence (i.e., 12-hour ER morphine given as 45 mg every 12 hours = 90 mg of Avinza every 24 hours). There are no published trials directly comparing the two 24-hour ER products.

The two products do have some differences. Avinza is a capsule containing both IR and ER beads of morphine sulfate. Therapeutic serum levels are achieved rapidly (~0.5 hour) and then maintained for 24 hours. At steady state, plasma concentrations remain constant (no peak-trough phenomenon). Avinza is restricted to a maximum dose of 1600 mg daily, since it contains fumarate and can cause renal toxicity. Alcohol, including alcohol-containing medications, cannot be taken with Avinza, since this can lead to a rapid dissolution of the ER granules and premature release of morphine.

Kadian capsules contain polymer-coated ER pellets of morphine sulfate, which release morphine slowly within the gastrointestinal tract. The time to achieve maximum serum levels (~9.5 hours) is much longer than with 12-hour ER morphine (2-3 hours) or Avinza (~0.5 hours).

Both products can be opened and sprinkled onto applesauce for patients who have trouble swallowing pills. Kadian granules can also be suspended in water and administered down a large bore (≥16 French) gastrostomy tube, which is not possible with 12-hour ER morphine or oxycodone products.

iv) Clinical evidence in constant non-cancer pain

The DERP report on long-acting narcotic analgesics for non-cancer pain included products requiring dosing three or fewer times per day, including transdermal fentanyl and oral oxycodone, morphine, methadone, levorphanol, codeine, dihydrocodeine, and oxymorphone.

- Based on direct evidence from head-to-head studies, the report found no differences between agents overall. Evidence included three RCTs comparing transdermal fentanyl and long-acting morphine (two fair-quality trials showed similar efficacy, one poor quality trial showed greater efficacy for transdermal fentanyl); one RCT showing similar efficacy for long-acting morphine once-daily versus twice daily; and one RCT showing equal efficacy between long-acting oxymorphone and long-acting oxycodone.
- Reviewers found no useful indirect evidence concerning comparative efficacy based on 20 clinical trials comparing narcotic analgesics to other agents or placebo; withdrawal rates did not suggest tolerability advantages for any one product.
- Reviewers further found no evidence to suggest greater efficacy for long-acting versus short-acting opioids, based on seven fair-quality trials. Based on three of these trials, they concluded that there was fair evidence that long- and short-acting oxycodone were equally effective for pain control.

A 2006 systematic review [Furlan *et al.*, 2006] included data from 41 trials of opioids (codeine, morphine, oxycodone, tramadol, or propoxyphene) for the treatment of chronic non-cancer pain. Results from a meta-analysis of 28 placebo-controlled trials favored opioids. A meta-analysis of eight trials comparing opioids to other agents (NSAIDs, TCAs) found no significant difference overall, although strong opioids (oxycodone, morphine) were significantly more effective than other agents. The review outlined adverse effect rates with opioids but did not provide useful detail regarding comparison of different agents.

A systematic review of eight trials [Devulder *et al.*, 2005] assessing functional and quality of life outcomes in patients with chronic non-cancer pain in general reported favorable results with opioids, but studies were too heterogeneous to allow comparison of agents.

v) Clinical evidence in breakthrough pain

Historically, the standard practice has been to use the same opioid for treatment of baseline and breakthrough pain (e.g., sustained release and IR morphine), although fentanyl patches are commonly used along with morphine IR for breakthrough pain. Narcotic analgesics offering both a long-acting formulation and a short-acting formulation include morphine, oxycodone, fentanyl, and oxymorphone.

Recent trials primarily focus on the newer fentanyl products: oral transmucosal lozenges (Actiq, generic) and buccal tablets (Fentora). There is insufficient comparative evidence to directly compare the two formulations. Buccal fentanyl is more bioavailable and may therefore offer more consistent dosing; it is also sugar-free, unlike the transmucosal lozenges. The two products cannot be switched at a 1:1 conversion due to the difference in bioavailability (for example, patients receiving 200 to 400 mcg of Actiq should start on 100 mcg of Fentora). A specific regimen is provided in Fentora labeling for converting from Actiq to Fentora (but not vice versa). From a safety standpoint, there is probably a significant potential for medication errors related to this conversion.

vi) Clinical evidence in neuropathic pain

Authors of a systematic review of double-blinded, placebo-controlled trials in neuropathic pain conditions [Finnerup *et al.*, 2005] attempted to use numbers-needed-to-treat (NNTs) to achieve one patient with 50% pain relief and numbers-needed-to-harm (NNHs) for one patient to drop out due to adverse effects to construct a treatment algorithm for neuropathic pain. The systematic review included 11 trials comparing opioids (morphine, oxycodone, methadone, or tramadol) to placebo. These trials showed evidence of efficacy for morphine in post-herpetic neuralgia and mixed neuropathic pain; oxycodone and tramadol in post-herpetic neuralgia and polyneuropathy, and methadone in post-herpetic neuralgia.

Authors concluded that if the proposed algorithm was based solely on NNTs for pain relief, it should place TCAs first, followed by opioids or gabapentin/pregabalin. However, taking into account quality of life measures and NNHs, the authors proposed an algorithm placing opioids as third-line therapy, following TCAs and gabapentin/pregabalin. A 2005 meta-analysis [Eisenberg *et al.*, 2005] that included most of the same trials but excluded tramadol found overall efficacy for opioids in neuropathic pain, compared to placebo.

Overall, while there is evidence that opioids are effective for neuropathic pain, there is insufficient evidence to conclude that there are differences in efficacy between agents. Evidence of efficacy in various types of neuropathic pain exists for morphine, oxycodone, tramadol, and methadone.

b) *Acute pain*

The clinical review divided acute pain into two types, based on etiology: non-specific pain (e.g., low back, neck, shoulder, arm, or extremity pain) and post-operative pain.

Data in acute pain consist primarily of a plethora of very small, short-term (including single-dose) trials, most commonly in patients with post-op pain, and meta-analyses of these trials. There is little clinical evidence specifically addressing non-specific acute pain.

The most coherent approach to making sense of the available data appears to be the Oxford League Table of Analgesic Efficacy, a resource maintained by the evidence-based medicine journal/site Bandolier. The "League Table" aggregates data from randomized, double-blind, single-dose studies in patients with moderate to severe pain, using the NNT to achieve at least 50% pain relief over 4 to 6 hours as a common measure. Despite reliability issues (confidence intervals are broad for agents with relatively small datasets and probably unreliable for datasets representing fewer than 250 patients), some tentative conclusions can be drawn:

- For the combination agents, the League table generally supports the common perception of relative efficacy (oxycodone/APAP > hydrocodone/APAP > codeine or propoxyphene/APAP).
- Overall, both opioid combination agents and tramadol compare relatively poorly with NSAIDs.

Sources addressing agents not included in the League table did not add substantially to available data. One double-blind RCT [White *et al.*, 1997] found similar efficacy with hydrocodone 7.5 mg/APAP 750 mg and ketorolac 10 mg given every 6 hours for up to 3 days following tubal ligation (although neither agent was regarded by authors as very effective). Ketorolac appeared to be more tolerable. A Cochrane review of 16 poor quality studies [Elbourne and Wiseman, 2006] comparing IM meperidine to tramadol or pentazocine concluded there was insufficient evidence to evaluate comparable efficacy and safety. More vomiting and drowsiness was noted with meperidine.

The VA/DoD guideline for postoperative pain draws few specific conclusions, but does advise against use of meperidine.

Overall, there is insufficient direct evidence to draw definitive conclusions regarding the relative efficacy of narcotic analgesics for treatment of acute pain, although the League table does give an overall impression of relative potency. Dosing of combination agents is limited by their non-opioid ingredient, most commonly acetaminophen.

c) *Efficacy conclusion*

The DoD P&T Committee concluded that:

a) All of the reviewed narcotic analgesics appear to be effective at providing analgesia when used in equipotent dosing. There is insufficient evidence to conclude that there are differences in efficacy between narcotic analgesics, including high potency long-acting agents for the treatment of chronic cancer or non-cancer pain, high potency IR agents for the treatment of breakthrough pain, or narcotic analgesics in general for the treatment of neuropathic pain.

b) Strong narcotic analgesics appear to be more effective than non-opioid analgesics (NSAIDs, TCAs) in chronic non-cancer pain.

c) There is no evidence suggesting efficacy differences between long-acting and short-acting formulations of the same agents; however, long-acting products offer greater convenience and may be associated with fewer episodes of breakthrough pain.

d) There is insufficient evidence to support efficacy differences between the 12-hour ER morphine products (e.g., MS Contin and generics) and the 24-hour ER morphine products (Avinza, Kadian), or between the two 24-hour products (Avinza versus Kadian). Avinza is restricted to a maximum dose of 1600 mg daily and cannot be taken with alcohol (including alcohol-containing medications). Kadian has a much longer time to achieve maximum serum levels (~9.5 hours) compared to Avinza (~0.5 hour) or to 12-hour ER morphine (2-3 hours). Both Avinza and Kadian capsules can be opened and sprinkled on food; Kadian granules can be given via gastrostomy tube.

e) Historically, the standard practice has been to use the same opioid for treatment of baseline and breakthrough pain (e.g., sustained release and IR morphine), although fentanyl patches are commonly used along with morphine IR for breakthrough pain. There is insufficient evidence to conclude that there are differences in efficacy between IR agents for the treatment of breakthrough pain in patients with chronic cancer or non-cancer pain. Trials focusing on the newer IR fentanyl products—oral transmucosal lozenges and buccal tablets—do not supply sufficient evidence to directly compare efficacy. Buccal fentanyl is more bioavailable and may therefore offer more consistent dosing; it is also sugar-free, unlike the transmucosal lozenges. The lack of a 1:1 conversion between the two formulations may offer significant potential for medication errors.

f) Narcotic analgesics are rarely considered first-line treatment for the treatment of neuropathic pain. There is insufficient evidence to conclude that there are differences in efficacy between agents. Evidence of efficacy in various types of neuropathic pain exists for morphine, oxycodone, tramadol, and methadone.

g) There is insufficient direct evidence to draw definitive conclusions regarding the relative efficacy of narcotic analgesics for treatment of acute pain, although the League table does give an overall impression of relative potency. Dosing of combination agents is limited by their non-opioid ingredient, most commonly acetaminophen.

2) Safety and Tolerability

a) General adverse effects

Narcotic analgesics are associated with an increased risk of nausea, vomiting and constipation. Other prominent adverse effects include mood changes (dysphoria, euphoria), somnolence, urinary retention (associated with increased sphincter tone), and urticaria/pruritis (associated with histamine

release). Respiratory depression is uncommon but potentially serious. Death secondary to opiate overdose is nearly always due to respiratory depression. When these agents are appropriately titrated, the risk of severe respiratory depression is generally small, as tolerance rapidly develops to this effect.

A decrease in seizure threshold occurs with the use of all narcotics and is of particular concern when these medications are given with other agents that lower seizure threshold or used in patients predisposed to seizure.

Codeine is often associated with gastrointestinal intolerance, which some patients incorrectly identify as an allergic reaction. True allergy to opiate agonists is uncommon. Narcotic analgesics may also decrease or inhibit salivary flow, contributing to oral/dental problems.

b) Drug-specific adverse effects

Meperidine – Neurotoxicity (anxiety, tremors, myoclonus, and generalized seizures) has been observed with repeated use of meperidine due to accumulation of a metabolite, normeperidine, which functions as a CNS excitotoxin. Patients using meperidine for more than two days, with pre-existing renal impairment, sickle-cell disease, or CNS disease, or receiving meperidine doses greater than 600 mg/24 hours are at particularly high risk for normeperidine toxicity. Use in children is not recommended.

Propoxyphene – Like meperidine, propoxyphene has CNS-excitatory metabolites and can cause CNS disturbances including seizure when administered in high doses, especially in patients with renal disease. Propoxyphene products in excessive doses, either alone or in combination with other CNS depressants (including alcohol), are a major cause of drug-related deaths (many of them in patients with histories of emotional disturbance, suicidal ideation or attempts, or misuse of tranquilizers, alcohol, and other CNS-active drugs). The consumer watchdog group Public Citizen petitioned the FDA in February 2006 to phase out propoxyphene from the U.S. market. Propoxyphene overdoses can be more difficult to reverse than with other opioids. Propoxyphene is not considered appropriate in elderly patients due to CNS adverse effects, including sedation, confusion, and increased likelihood of falls and fall-related fractures. It is one-half to two-thirds as potent an analgesic as codeine.

Many DoD providers surveyed cited concerns for safety with the use of meperidine and propoxyphene, although others pointed out that they were useful and could be used safely if limited to short-term use in the correct patients.

Tramadol – Doses of tramadol are limited by its association with an increased risk of seizure at higher than recommended doses. Per labeling, total dose should not exceed 300 mg of tramadol per day for the ER tablets (Ultram ER) and tramadol/APAP combination (Ultracet, generics), or 400 mg per day for tramadol IR tablets (Ultram, generics). Tramadol may increase seizure risk in

patients with a history of seizures, conditions with a recognized risk of seizure, or taking other medications that increase seizure risk.

Oral transmucosal and buccal fentanyl citrate are IR, high potency products indicated only for the management of breakthrough cancer pain in patients with malignancies who are already receiving and tolerant of opioid therapy for their underlying persistent cancer pain. Patients considered opioid tolerant are those who have been taking morphine 60 mg/day or more, transdermal fentanyl 50 mcg/h, or an equianalgesic dose of another opioid for a week or longer. These products should not be used in opioid non-tolerant patients because life-threatening hypoventilation could occur at any dose in patients not taking chronic opiates. They are contraindicated in the management of acute or postoperative pain. Patients requiring more than four doses per day should have their maintenance analgesic reevaluated; use of round-the-clock oral transmucosal or buccal fentanyl citrate is not recommended.

Transdermal fentanyl is indicated for management of persistent, moderate to severe chronic pain requiring continuous, around-the-clock administration for an extended period of time, that cannot be managed by other means, and ONLY in patients who are already receiving opioids, have demonstrated opioid tolerance, and require a total daily dose at least equivalent to fentanyl 25 mcg/hr. It should not be used for management of acute pain or short periods of opioid analgesia; post-op pain, including outpatient/day surgeries; mild pain; or intermittent pain. The DoD P&T Committee agreed in November 2006 that a PA was needed for transdermal fentanyl; the recommendation was approved by the Director, TMA in January 2007. Please see the November 2006 DoD P&T minutes for more information.

c) *Potential for abuse*

Numerous factors determine how and whether a drug is abused. It is generally accepted that rapidly acting medications (or ER dosage systems that can be compromised to cause drug to become rapidly available) are more prone to abuse than slow-acting or ER medications. Factors such as availability, local market conditions, drug popularity, and drug abuse culture may very greatly among geographic areas. Prescriptions for C-III to C-V controlled medications can generally be phoned in to pharmacies, written with refills, and are not tracked in statewide databases. This makes them easier to obtain through fraudulent activity (e.g., forging prescriptions). Prescriptions for C-II controlled medications, which have restrictions on telephone orders, cannot be refilled, and are usually tracked at the state level, are more difficult to obtain but are also more desirable to addicts due to their higher potency. Clearly there are differences among narcotic analgesics with regard to these factors; however, there were no data supporting differences in potential for abuse among like medications (for example, comparing the various long-acting high potency formulations) that the P&T Committee considered useful for making formulary recommendations.

d) Drug interactions

A large number of medications may interact with the narcotic analgesics. In general, these drug interactions are relatively similar for all of the drugs in this class and do not suggest that any particular medication offers a substantially higher potential for drug interactions. One unique consideration arises due to the dual mechanism of action of tramadol, leading to potential interactions (including increased risk of seizures or serotonin syndrome) with other medications that increase levels of serotonin and/or norepinephrine (e.g., MAOIs and selective serotonin reuptake inhibitors [SSRIs]). Another is the potential for a lethal hyperpyrexic syndrome with delirium if meperidine is administered to patients receiving MAOIs; this combination is contraindicated.

e) Special populations

There are differences among narcotic analgesics with regard to clinical evidence, extent of clinical experience, and labeling for use in special patient populations (including pediatric and elderly patients, patients who are pregnant or breast-feeding, and patients with renal or hepatic dysfunction). However, the P&T Committee overall did not find sufficient evidence of a unique advantage or disadvantage for specific products that it considered useful for formulary decision-making.

Patients with swallowing difficulties may require liquid formulations or products that can be sprinkled on food or administered via a non-oral route (e.g., as a transdermal patch, nasal spray, buccal tablet, transmucosal lozenge, or rectal suppository). The available narcotic analgesics offer various formulations that meet these needs (see Table 1).

3) Provider Opinion

The P&T Committee reviewed survey responses from 342 MHS healthcare providers with experience in prescribing narcotic analgesics for the treatment of pain. Responders represented more than 40 specialties (including a number of dental specialties), reflecting the ubiquity of use of the narcotic analgesics in clinical practice; however, the majority of responders were from Family Practice, Internal Medicine, and General Surgery. Overall, providers emphasized that they require a broad array of narcotic analgesics in their practice to treat their patients and that excessive formulary restrictions would be detrimental to their ability to adequately treat various clinical presentations. They favored ER narcotic analgesics, including the fentanyl transdermal patch, as well as a broad array of strengths of opioid/acetaminophen combination products.

The P&T Committee also reviewed comments from MTF pharmacists regarding the ability of their facilities to accommodate additional controlled substances if placed on the BCF, which would require additional vault space and increase administrative burden (i.e., performing narcotic counts) for MTFs that did not already have the additional medications on formulary. Many pharmacists indicated that centralized contracting for “pre-packed” products in commonly-

dispensed quantities would facilitate inventory and dispensing requirements at their facilities.

4) Clinical Coverage Considerations

The issue of clinical coverage, or "how many agents do we need on formulary to meet the majority of patients' needs," is dependent on multiple factors, including the efficacy, safety, and tolerability of individual agents for the treatment of conditions in which they are used, the needs of specific subpopulations, how interchangeable the medications are, the degree of intra-patient variability, and whether or not patients failing one agent (due to lack of efficacy, adverse effects, or hypersensitivity) typically respond to or tolerate another. In the case of the narcotic analgesics, several factors support availability of multiple agents and formulations.

- There is evidence that patients failing one narcotic analgesic due to lack of efficacy may respond better to another.
- Patients allergic to medications in one chemical class may be able to tolerate another without cross-sensitivity (i.e., may be able to take a phenylheptane [e.g., methadone] if allergic to a phenanthrene [e.g., morphine]).
- As with other pain medications, there is substantial intra-patient variability in response. Rotation of different narcotic analgesics has been proposed as a strategy to increase efficacy and decrease adverse effects, although clinical data are limited.
- Alternative formulations (e.g., liquids, suppositories, or patches) are needed in some patient populations. Long-acting products may be desirable not only for convenience, but to provide more blood concentrations and reduce the number of episodes of breakthrough pain.
- Utilization of these agents spreads across the entire population and touches virtually every disease state and professional specialty. Differences in clinical practice exist both locally and by specialty (e.g., products typically used in dental practice).

5) Narcotic Analgesics – Overall Clinical Effectiveness Conclusion

The P&T Committee concluded that:

a) There is insufficient evidence to support efficacy differences between narcotic analgesics, including high potency long-acting agents for the treatment of chronic cancer or non-cancer pain, high potency IR agents for the treatment of breakthrough pain, or narcotic analgesics in general for the treatment of neuropathic pain.

b) Strong narcotic analgesics appear to be more effective than non-opioid analgesics (NSAIDs, TCAs) in chronic non-cancer pain.

c) There is no evidence suggesting efficacy differences between long-acting and short-acting formulations of the same agents; however, long-acting products

offer greater convenience and may be associated with fewer episodes of breakthrough pain.

d) There is insufficient evidence to support efficacy differences between 12-hour (e.g., MS Contin and generics) and 24-hour ER morphine products (Avinza, Kadian), or between the two 24-hour products (Avinza versus Kadian). Avinza is restricted to a maximum dose of 1600 mg daily and cannot be taken with alcohol (including alcohol-containing medications). Kadian has a much longer time to achieve maximum serum levels (~9.5 hours) compared to Avinza (~0.5 hour) or to 12-hour ER morphine (2-3 hours). Both can be opened and sprinkled on food; Kadian granules can be given via gastrostomy tube.

e) There is insufficient evidence to support efficacy differences between IR agents for the treatment of breakthrough pain in patients with chronic cancer or non-cancer pain, including the newer IR fentanyl products (oral transmucosal lozenges and buccal tablets). Buccal fentanyl is more bioavailable and may offer more consistent dosing; it is also sugar-free. The lack of a 1:1 conversion between the two IR fentanyl products may offer significant potential for medication errors.

f) Narcotic analgesics are rarely considered first line agents for the treatment of neuropathic pain. There is insufficient evidence to support efficacy differences between agents. Evidence of efficacy in various types of neuropathic pain exists for morphine, oxycodone, tramadol, and methadone.

g) There is insufficient direct evidence to draw definitive conclusions regarding the relative efficacy of narcotic analgesics for treatment of acute pain. Dosing of combination agents is limited by their non-opioid ingredient, most commonly acetaminophen. The VA/DoD guideline recommends avoiding meperidine for the treatment of postoperative pain.

h) Narcotic analgesics are associated with multiple adverse effects, including nausea, vomiting, constipation, mood changes, somnolence, urinary retention, pruritis, and oral/dental problems. Respiratory depression is uncommon but potentially serious; the risk is generally small when narcotic analgesics are appropriately titrated, as tolerance rapidly develops.

i) A decrease in seizure threshold occurs with the use of all narcotics, but is of particular concern with meperidine (which has a neurotoxic metabolite and should not be used for more than two days, in patients with renal impairment, sickle-cell disease, or CNS disease, or in children); propoxyphene (which also has CNS-excitatory metabolites and can cause seizure in high doses, especially in patients with renal disease); and tramadol (which is associated with an increased risk of seizure at higher than recommended doses [300-400 mg daily] or in patients taking other medications or with conditions that increase seizure risk).

j) Propoxyphene is not considered appropriate in elderly patients due to CNS adverse effects, including sedation, confusion, and increased likelihood of

falls and fall-related fractures. The consumer watchdog group Public Citizen has petitioned the FDA to phase out propoxyphene from the U.S. market due to the association of excessive doses of propoxyphene with drug-related deaths. Many DoD providers surveyed cited concerns for safety with the use of meperidine and propoxyphene, although others pointed out that they were useful and could be used safely if limited to short-term use in the correct patients.

k) While there are clearly differences among narcotic analgesics with regard to likelihood for abuse (e.g., onset of action and potency), there are no data supporting differences in potential for abuse among like medications (e.g., high potency, long-acting agents) that the P&T Committee considered useful for making any formulary recommendation.

l) In general, drug interactions are relatively similar for all of the drugs in this class and it does not appear that any particular medication offers a substantially higher potential for drug interactions. Two unique considerations are tramadol and meperidine. Because of its dual mechanism of action, tramadol has potential interactions with other medications that increase serotonin and/or norepinephrine levels (e.g., MAOIs, SSRIs); meperidine is contraindicated with MAOIs due to the potential for a lethal hyperpyrexic syndrome.

m) There are differences among narcotic analgesics with regard to clinical evidence, extent of clinical experience, and labeling for use in special patient populations (including pediatric and elderly patients, patients who are pregnant or breast-feeding, and patients with renal or hepatic dysfunction). However, the P&T Committee overall did not find sufficient evidence of a unique advantage or disadvantage for specific products that it considered useful for formulary decision-making.

n) Patients with swallowing difficulties may require liquid formulations or products that can be sprinkled on food or administered via a non-oral route. The available narcotic analgesics offer various formulations that meet these needs.

o) Providers surveyed in general emphasized that they require a broad array of narcotic analgesics in their practice to treat their patients and that excessive formulary restrictions would be detrimental to their ability to adequately treat various clinical presentations. They favored ER narcotic analgesics, including the fentanyl transdermal patch, as well as a broad array of strengths of opioid/ acetaminophen combination products. Many pharmacists indicated that centralized contracting for “pre-packed” products in commonly-dispensed quantities would facilitate inventory and dispensing requirements at their facilities.

p) Clinical coverage considerations support a broad array of formulary agents and formulations.

COMMITTEE ACTION: The P&T Committee voted (15 for, 0 opposed, 1 abstained, 1 absent) to accept the clinical effectiveness conclusions stated above.

B. Narcotic Analgesics – Relative Cost Effectiveness

The P&T Committee evaluated the relative cost effectiveness of the agents in the narcotic analgesic therapeutic class in relation to the efficacy, safety, tolerability, and clinical outcomes of the other agents in the class. Information considered by the P&T Committee included but was not limited to sources of information listed in 32 CFR 199.21(e)(2).

Cost minimization analyses (CMAs) were conducted for four subclasses of the narcotic analgesics, which differed slightly from the categories used during the clinical review: (1) long-acting high potency single analgesic agents; (2) short-acting high potency single analgesic agents; (3) low potency single analgesic agents; and (4) combination products. The conclusion of the relative clinical effectiveness evaluation was that there was insufficient evidence to suggest that the narcotic analgesics differed within the defined subclasses (long-acting high potency agents, short-acting high potency agents, low potency agents, and combination products) in regards to efficacy, safety, tolerability, or clinical outcomes in the treatment of pain. As a result, several CMAs were performed to determine the relative cost effectiveness of the agents within each subclass. The CMAs compared the agents based on their weighted average cost per equianalgesic dose.

The results of the CMA for the high potency long-acting single analgesic agents showed that the 12-hour morphine sulfate ER product (MS Contin, generics) was the most cost effective agent. This result was anticipated since this product is generically available at a significantly discounted cost relative to brand name MS Contin. The other long-acting high potency single analgesic agents—the 24-hour ER morphine products (Kadian, Avinza), fentanyl patch, oxycodone ER, and oxymorphone ER—were considerably more costly relative to the 12-hour morphine sulfate ER product (MS Contin, generics). Two of these products, fentanyl patch and oxycodone ER only recently became generically available. The cost of these generics is only slightly lower than their respective brand name products. The other three long-acting high potency single analgesic agents—the 24-hour ER morphine products (Kadian, Avinza) and oxymorphone ER—are brand-only products. There was no substantial difference in cost effectiveness between Kadian and Avinza.

The results of the CMA for the high potency short-acting single analgesic agents showed that morphine sulfate IR and oxycodone IR had similar relative cost effectiveness and were the most cost effective agents. Once again, this result was anticipated since morphine sulfate IR and oxycodone IR are now generically available at a significantly discounted cost relative to the their respective brand name products. The other two agents, fentanyl citrate buccal tablets and fentanyl citrate transmucosal lozenges, were 40-fold the cost of the two most cost effective agents. Fentanyl citrate transmucosal lozenges only recently became generically available. There was no substantial difference in cost effectiveness between the two fentanyl citrate products (Fentora versus Actiq or its generic equivalent).

The results of the CMA for the low potency single analgesic agents showed that tramadol ER was not cost effective relative to other formulations of tramadol (tramadol; tramadol/APAP), which are generically available.

The CMA for the combination agents showed that the agents within this generic-dominated class were all similar in terms of relative cost effectiveness.

The P&T Committee's discussion primarily focused on the relative clinical and cost effectiveness of the high potency long-acting and high potency short-acting single analgesic agents. The general consensus of the P&T Committee was that the UF should provide a broad array of these agents sufficient to meet the clinical needs of the DoD population. The P&T Committee made the following conclusions for each of these two subclasses:

1) *High potency long-acting single analgesic agents* – Although the 24-hour ER products (Kadian and Avinza); fentanyl transdermal patch, oxycodone ER, and oxymorphone ER were considerably more costly relative to the 12-hour morphine sulfate ER product (MS Contin and generics), these agents should be maintained on the UF in order to sufficiently meet the clinical needs of the DoD population. This conclusion was based on the following factors:

    a. The 24-hour ER morphine products (Kadian and Avinza) provide more consistent levels of medication throughout a 24-hour period, which may reduce the number and/or severity of breakthrough pain episodes. Both products can be sprinkled on food to ease administration for patients who cannot swallow oral solid dosage forms. There was no substantial difference in cost effectiveness between Kadian and Avinza.

    b. Oxycodone ER provides an alternative for patients who cannot tolerate morphine sulfate.

    c. Transdermal fentanyl provides a unique dosage form for patients who are unable to swallow.

    d. Oxymorphone ER provides an additional long-acting oral alternative for patients who cannot tolerate morphine sulfate or oxycodone. The place of oxymorphone in therapy relative to other long-acting narcotic analgesics with much longer periods of clinical experience is not yet clear.

2) *High potency short-acting single analgesic agents* – Even though fentanyl citrate buccal tablets and fentanyl citrate transmucosal lozenges were more than 40-fold the cost of the two most cost effective agents, morphine sulfate IR and oxycodone IR, the fentanyl citrate products provide an additional therapeutic alternative for breakthrough pain with novel routes of administration. There was no substantial difference in cost effectiveness between the two fentanyl citrate products.

Cost Effectiveness Conclusion

1) *High potency long-acting single analgesic agents* – Although the 24-hour ER products (Kadian and Avinza); fentanyl transdermal patch, oxycodone ER, and oxymorphone ER were considerably more costly relative to the 12-hour morphine sulfate ER product (MS Contin and generics), they have unique clinical

advantages and should be maintained on the UF in order to sufficiently meet the clinical needs of the DoD population.

2) *High potency short-acting single analgesic agents* – Even though fentanyl citrate buccal tablets and fentanyl citrate transmucosal lozenges were more than 40-fold the cost of the two most cost effective agents, morphine sulfate IR and oxycodone IR, the fentanyl citrate products provide an additional therapeutic alternative for breakthrough pain with novel routes of administration. There was no substantial difference in cost effectiveness between the two fentanyl citrate products.

3) *Low potency single analgesic agents* – Tramadol ER was not cost effective relative to other formulations of tramadol (tramadol; tramadol/APAP), which are generically available. All other products in this subclass were cost effective.

4) *Combination agents* – The products within this generic-dominated subclass were all determined to be cost effective relative to their comparators.

The P&T Committee agreed (14 for, 0 opposed, 1 abstained, 2 absent) with the relative cost effectiveness analysis of the narcotic analgesic agents.

C. Narcotic Analgesics – UF Recommendations

COMMITTEE ACTION: Taking into consideration the conclusions from the relative clinical effectiveness and the relative cost effectiveness determinations for the narcotic analgesic drug class, and other relevant factors, the P&T Committee recommended (14 for, 0 opposed, 1 abstained, 2 absent) that tramadol ER tablets be designated non-formulary under the UF, with all other narcotic analgesic agents designated as formulary on the UF. Additionally, the P&T Committee voted to recommend (14 for, 0 opposed, 1 abstained, 1 absent) a QL of 112 tablets/28 days for fentanyl buccal tablets, consistent with established quantity limits for fentanyl transmucosal lozenges, recommendations in Fentora package labeling, and current DoD prescribing patterns for Fentora buccal tablets.

D. Narcotic Analgesics – MN Criteria

Based on the clinical evaluation for tramadol ER and the conditions for establishing MN for a non-formulary medication provided for in the UF rule, the P&T Committee recommended the following general MN criteria for tramadol ER:

1) Use of formulary alternatives is contraindicated.

2) The patient previously responded to tramadol ER and changing to a formulary alternative would incur unacceptable clinical risk.

The P&T Committee did not agree that other MN criteria were likely to apply, given the UF status of tramadol IR.

COMMITTEE ACTION: The P&T Committee voted (13 for, 0 opposed, 1 abstained, 3 absent) to approve the MN criteria outlined above.

E. Narcotic Analgesics – UF Implementation Period

Because of the small number of unique utilizers affected (approximately 6500 patients [~1.5%] out of approximately 437,000 unique utilizers at all three points of

service), the P&T Committee recommended an effective date of the first Wednesday following a 90-day implementation period. The implementation period will begin immediately following approval by the Director, TMA.

MTFs will not be allowed to have tramadol ER on their local formularies. MTFs will be able to fill non-formulary requests for this medication only if both of the following conditions are met: 1) the prescription must be written by a MTF provider, and 2) MN is established. MTFs may (but are not required to) fill a prescription for a non-formulary narcotic analgesic written by a non-MTF provider to whom the patient was referred, as long as MN has been established.

COMMITTEE ACTION: The P&T Committee recommended (13 for, 0 opposed, 1 abstained, 3 absent) an effective date of the first Wednesday following a 90-day implementation period. The implementation period will begin immediately following the approval by the Director, TMA.

F. Narcotic Analgesics – BCF Review and Recommendation

The P&T Committee considered the BCF status of the narcotic analgesics. Currently the only narcotic analgesic agents on the BCF are the 15 mg, 30 mg, and 60 mg strengths of morphine sulfate ER (MS Contin, generics); codeine/APAP oral (formulations not specified), and oxycodone/APAP 5/325 mg or 5/500 mg tablets. In addition to the medications already on the BCF, the P&T Committee agreed that morphine sulfate IR 15 and 30 mg and tramadol IR 50 mg should be added to the BCF and that the listings for hydrocodone/APAP and codeine/APAP should be clarified to specify the most commonly used and clinically necessary formulations and strengths (hydrocodone / APAP 5/500 mg; codeine/APAP 30/300 mg, and codeine/APAP elixir 12/120 mg per 5 mL). All of these drugs are cost effective, widely used agents in the MTF setting.

COMMITTEE ACTION: The P&T Committee voted (14 for, 0 opposed, 1 abstained, 2 absent) to recommend the following agents be designated as the BCF selections in this class: morphine sulfate ER 15 mg, 30 mg, 60 mg; morphine sulfate IR 15 mg and 30 mg; oxycodone/APAP 5/325 mg; hydrocodone/ APAP 5/500 mg; codeine/APAP 30/300 mg; codeine/APAP elixir 12/120 mg per 5 mL; and tramadol IR 50 mg.

8. DRUG CLASS REVIEW – OPHTHALMIC GLAUCOMA AGENTS

The P&T Committee evaluated the relative clinical effectiveness of the ophthalmic glaucoma agents. Based on chemical structure and mechanism of action, the drug class was divided into seven categories as outlined in Table 2. The seven categories include ophthalmic prostaglandin analogs; beta blockers; carbonic anhydrase inhibitors; alpha 2 adrenergics; adrenergics; cholinergics; and cholinesterase inhibitors. The glaucoma drug class accounted for $51.1 million in MHS expenditures in FY 2006, and is ranked #34 in terms of total expenditures during that time period.

A. Ophthalmic Glaucoma Agents – Relative Clinical Effectiveness

The P&T Committee evaluated the relative clinical effectiveness of the ophthalmic glaucoma agents currently marketed in the U.S. Information regarding the safety, effectiveness, and clinical outcomes of these drugs was considered. The clinical

review included, but was not limited to, the requirements stated in the UF Rule, 32 CFR 199.21(e)(1). The P&T Committee was advised that there is a statutory presumption that pharmaceutical agents in a therapeutic class are clinically effective and should be included on the UF, unless the P&T Committee finds by a majority vote that a pharmaceutical agent does not have a significant, clinically meaningful therapeutic advantage in terms of safety, effectiveness, or clinical outcome over the other pharmaceutical agents included on the UF in that therapeutic class.

Table 2: Ophthalmic Glaucoma Agents Available in the U.S.

Subclass	Generic Name	Brand Name
Prostaglandin Analogs	Bimatoprost Latanoprost Travoprost	Lumigan Xalatan Travatan; Travatan Z
Beta Blockers	Betaxolol Carteolol Levobunolol Metipranolol Timolol maleate solution Timolol maleate gel-forming solution Timolol maleate with potassium sorbate Timolol hemihydrate	Betoptic, generics; Betoptic-S Ocupress, generics Betagan, generics Optipranolol, generics Timoptic, generics Timoptic XE, generics Istalol Betimol
Carbonic Anhydrase Inhibitor; Combination Drug	Brinzolamide Dorzolamide Dorzolamide / timolol	Azopt Trusopt Cosopt
Alpha 2 adrenergics	Brimonidine BAK 0.2% Brimonidine Purite 0.15%/ 0.1% Apraclonidine	Generic (Alphagan brand discontinued) Alphagan P Iopidine
Adrenergics	Dipivefrin	Propine, generics
Cholinergics (miotics)	Acetylcholine Carbachol Pilocarpine	Miochol-E Isopto Carbachol Pilocar, generics; Pilopine HS gel
Cholinesterase Inhibitors	Echothiophate	Phospholine iodide

1) Efficacy Measures

The primary outcome measure used to assess efficacy of the glaucoma drugs is the change in intraocular pressure (IOP) as compared to baseline, expressed as an absolute value in mm Hg or as a relative percentage change from baseline.

2) Efficacy

a) Prostaglandin analogs

i) Products – The prostaglandins available on the market include bimatoprost (Lumigan), latanoprost (Xalatan), and travoprost (Travatan). These three products contain benzalkonium chloride (BAK) as a preservative, which has been associated with local ocular irritation. Travoprost is also available with a non-BAK preservative under the trade name of Travatan Z. None of the products are available in generic formulations.

ii) Meta-analyses – The efficacy of the ophthalmic prostaglandin analogs was evaluated in two meta-analyses. At peak levels, the mean differences from baseline IOP were similar; -33% (95% CI -29% to -27%) with bimatoprost,

-28% (95% CI -30% to -26%) with latanoprost, and -29% (95% CI -32% to -25%) with travoprost [Van der Valk *et al.*, 2005].

Ni Li *et al.* in 2006 found no difference in the IOP lowering effects when travoprost was compared to bimatoprost (weighted mean difference 0.08, 95% CI -0.62 to 0.79; p=0.8), or to latanoprost (weighted mean difference 0.57, 95% CI -1.18 to 0.04; p = 0.07). The IOP lowering efficacy of bimatoprost was not directly compared to latanoprost.

iii) Head-to-head trials – Two RCTs that evaluated the prostaglandin analogs in a head-to-head manner did not find significant differences in the efficacy of the drugs. Parrish *et al.* in 2003 found no difference among all comparison groups (p = 0.128), while Orzalesi *et al.* in 2006 reported that the performance of all three drugs was statistically identical within the 1.5 mmHg power of the trial.

iii) Racial differences in efficacy – Travoprost was more effective than latanoprost at lowering IOP in African Americans than non-African Americans in one sub-analysis [Netland *et al.*, 2001]. The difference of up to 1.5 mm Hg was statistically significant (p = 0.04) in favor of travoprost. However, this was a post-hoc analysis that was not prospectively designed to evaluate racial differences in efficacy.

No significant differences between bimatoprost and travoprost in mean IOP-lowering were found in one prospectively designed trial involving ninety-four African American patients [Noecker *et al.*, 2006]. Both drugs resulted in a statistically significant reduction from baseline IOP at all study visits ($p < 0.001$). There were no statistically significant between-group differences in IOP-lowering ($p \geq 0.130$).

b) Beta blockers

i) Products – Six ophthalmic beta blockers are included in the class; one β1 selective product, betaxolol (Betoptic-S, Betoptic); and five non-selective products, levobunolol (Betagan), metipranolol (OptiPranolol), timolol hemihydrate (Betimol), timolol maleate (Timoptic, Istalol, Timoptic Ocudose and Timoptic XE, a gel-forming solution), and carteolol (Ocupress).

ii) Generics – Several beta blockers are available in generic formulations, with the exception of betaxolol suspension 0.25% (Betoptic-S), timolol hemihydrate (Betimol), the branded timolol maleate product Istalol, and preservative free unit dose timolol maleate (Timoptic Ocudose).

iii) Timolol – Timolol was the first beta blocker marketed and is the gold standard to which other ophthalmic glaucoma agents are compared. On average, timolol reduces IOP by 20% to 35%. Several different formulations and salts are available:

- *Timolol maleate solution (Timoptic, generics) versus timolol maleate gel-forming solution* – Timolol maleate solution requires twice daily

dosing. Timolol maleate gel-forming solution is dosed once daily, and potentially has increased ocular penetration and duration of action compared to the solution, but causes transient blurred vision. One study comparing the solution with the gel-forming solution found no difference in IOP-lowering from baseline; both products lowered IOP by 30% to 31%.

- *Timolol hemihydrate* – The timolol hemihydrate salt theoretically enhances ocular drug availability, due to increased solubility compared to timolol maleate. The hemihydrate formulation is dosed twice daily, as is timolol maleate. Two comparative studies of timolol hemihydrate with timolol maleate solution or timolol maleate gel-forming solution showed similar reductions in IOP from baseline by about 22%. One study [Mundorf *et al.*, 1998] found there was no change in IOP after three months when patients previously receiving timolol maleate solution were switched to timolol hemihydrate.
- *Timolol maleate (Istalol)* – The timolol maleate branded product Istalol is dosed once daily. Potassium sorbate is incorporated into the formulation, which purportedly enhances ocular penetration into the eye. However, a clinical trial comparing Istalol to timolol maleate (Timoptic, generics) dosed twice daily demonstrated no efficacy differences between the products, both drugs reduced IOP by 23% to 24% [Mundorf *et al.*, 2004].

iv) Levobunolol, metipranolol, carteolol – Comparative trials with the non-selective beta blockers levobunolol, metipranolol, and carteolol each with timolol maleate (Timoptic, generics) show similar reductions in IOP.

vi) Betaxolol – Betaxolol is the sole β_1 selective ophthalmic beta blocker. It is available in two strengths, a 0.25% suspension (Betoptic-S) that is not available in a generic formulation, and a 0.5% solution (Betoptic, generics). Clinical trial data suggest that timolol maleate may decrease IOP to a greater extent than betaxolol. Due to betaxolol's β_1 selectivity, patients with respiratory or reactive airway diseases may not experience adverse pulmonary effects seen with non-selective beta blockers. However, there is only one published study enrolling nine subjects demonstrating a lack of adverse effect on pulmonary function tests.

c) Carbonic anhydrase inhibitors; combinations with beta blockers

i) Products – The ophthalmic carbonic anhydrase inhibitors include brinzolamide (Azopt), and dorzolamide (Trusopt). The branded product Cosopt consists of dorzolamide and timolol maleate and is the only combination glaucoma product marketed. Generic formulations of the three products are not available. The carbonic anhydrase inhibitors are used in patients with contraindications to other glaucoma drugs, and can be used concomitantly with other drugs that lower IOP. Brinzolamide and dorzolamide both decrease intraocular pressure by 15%-26%.

ii) Meta-analysis – One meta-analysis included an indirect comparison of brinzolamide and dorzolamide. Both drugs significantly reduced IOP, compared with placebo. At trough levels, the mean differences from baseline IOP were similar; -17% (95% CI -19% to -15%) for both drugs [Van der Valk *et al.*, 2005].

Head-to-head trials – One randomized trial reported similar reductions in IOP with brinzolamideand dorzolamide (-17% to -20% for both), compared to increases in IOP of 8% to 19% with placebo [Sall *et al.*, 2000]. When brinzolamide and dorzolamide were given with timolol maleate, similar IOP reductions were also seen (-14% to -21% for both) [Michaud *et al.*, 2001]. Similar absolute reductions in IOP of 0.1 to 0.3 mm Hg were reported with brinzolamide and dorzolamide when the carbonic anhydrase inhibitor was added on to a regimen of latanoprost and timolol (Timoptic, generics) [Tsukamoto *et al.*, 2005].

iii) Dorzolamide/timolol (Cosopt) – Clinical trials sponsored by the manufacturer lasting 3 to 15 months found the combination of dorzolamide with timolol produced similar reductions in IOP as the two separate components administered together. The net effect of administering the Cosopt combination is an absolute IOP reduction of 3-4 mm Hg below that seen with timolol (Timoptic, generics).

d) Alpha 2 adrenergics

i) Products – The alpha 2 adrenergic agents include the parent compounds of apraclonidine (Iopidine) and brimonidine. Brimonidine is available in three formulations: a 0.2% concentration with BAK as a preservative (available only as a generic, as the proprietary product has been discontinued); a 0.15% solution with purite as a preservative (Alphagan P), and a 0.1% solution with purite as a preservative (also called Alphagan P). Apraclonidine and brimonidine reduce intraocular pressure by 18% to 27% two to five hours after dosing and by 10% at 8 to 12 hours after administration.

ii) FDA Indications – There are differences in the FDA-approved indications for apraclonidine and brimonidine. All formulations of brimonidine BAK 0.2% (generic) and brimonidine purite 0.15% and 0.1% (Alphagan P) are indicated to reduce IOP in patients with glaucoma. Apraclonidine is approved for use following laser procedures to control post-surgical IOP elevations (1% concentration), or for short-term use in patients receiving maximally tolerated medical therapy who require additional IOP reductions prior to surgery (0.5% concentration).

iii) Apraclonidine – Apraclonidine is primarily used short-term, as it is associated with tachyphylaxis and diminished intraocular pressure lowering effect over time. DoD utilization of apraclonidine represents a small percentage of overall alpha 2 adrenergic drug use (0.5%).

iv) Apraclonidine versus brimonidine 0.2% BAK – Head-to-head studies of brimonidine BAK 0.2% and apraclonidine demonstrated similar intraocular

pressure lowering effects, both in patients with glaucoma, and in laser surgery. Both agents lower intraocular pressure by 17 to 26% in this setting.

v) Brimonidine – One meta-analysis reported that brimonidine reduced intraocular pressure by 25% at peak and 18% at trough, but to a lesser extent than the prostaglandins (25% to 35%) [Van der Valk *et al.*, 2005].

Brimonidine formulations – Two head-to-head trials comparing brimonidine BAK 0.2% formulation (generic) with brimonidine purite 0.15% (Alphagan P) did not show differences in IOP lowering [Katz *et al.*, 2002; Mundorf *et al.*, 2003]. One comparative trial with brimonidine purite 0.1% (Alphagan P) reported similar efficacy with brimonidine BAK 0.2% (generic), but few details were provided [package insert]. Product labeling states that the brimonidine purite 0.15% (Alphagan P) and brimonidine purite 0.1% (Alphagan P) both lower IOP by 2-6 mmHg; no corresponding percentage reduction in intraocular pressure was provided.

e) Adrenergics, cholinergics, and cholinesterase inhibitors

i) Products – Dipivefrin (Propine, generic) is the only ophthalmic adrenergic, and echothiophate (Phospholine iodide) is the only ophthalmic cholinesterase inhibitor. The cholinergics include acetylcholine (Miochol-E), carbachol (Isopto Carbachol), and pilocarpine gel (Pilopine HS) and pilocarpine solution (Pilocar, generics). The adrenergics, cholinergics, and cholinesterase inhibitors were introduced in the early 1980s, and were the first agents used to treat glaucoma, but have been replaced by newer therapies, due to adverse effects. They are now third-line treatments for glaucoma, but do fulfill unique niches in therapy.

ii) Dipivefrin – Dipivefrin is a pro-drug that has improved lipophilicity and enhanced corneal penetration compared to the parent compound epinephrine. IOP reduction with dipivefrin ranges from 15% to 25%.

iii) Cholinergics – The direct-acting cholinergics or miotics are used for glaucoma to decrease IOP via increased aqueous outflow, or are used to induce miosis during surgery. Acetylcholine, carbachol and pilocarpine solution are all dosed four times daily; only pilocarpine solution is available generically.

Acetylcholine – Acetylcholine is used intraocularly to constrict the pupil during cataract surgery, or after placement of the intraocular lens following cataract removal.

Carbachol – Carbachol has two mechanisms to decrease IOP; it directly stimulates muscarinic receptors in the eye, and indirectly inhibits acetylcholinesterase.

Pilocarpine – Pilocarpine lowers IOP by 22% to 30%. It is dosed four times daily in the treatment of open-angle glaucoma. In acute angle closure glaucoma, pilocarpine is used as monotherapy or in combination with other cholinergic agents or with a carbonic anhydrase inhibitor to relieve IOP prior to ocular surgery. Pilocarpine gel is a sustained release formulation

that is applied at bedtime to provide 24-hour control of IOP; pilocarpine gel reduces the adverse effects of myopia.

iv) Echothiophate – Echothiophate is dosed twice daily for glaucoma. It has a role for the treatment of aphakia or pseudophakia (patients with their lens replaced by artificial lens). The drug is poorly absorbed due to its quaternary structure, but has similar IOP reductions as pilocarpine.

3) Safety / tolerability

a) Prostaglandin analogs

i) Serious adverse events – Overall the ophthalmic prostaglandins have a low incidence of systemic adverse effects, which has contributed to their use as first-line therapy for glaucoma.

ii) Minor adverse events

- *Hyperemia* is the most common minor adverse event reported with the ophthalmic prostaglandins. A comparison of package insert data shows a higher incidence of hyperemia with bimatoprost (15-45%) and travoprost (30-50%), as compared to latanoprost (5-15%). In one head-to-head trial, hyperemia occurred in 69% of patients receiving bimatoprost, 58% of travoprost-treated patients, and 47% of latanoprost-treated patients [Parrish *et al.*, 2003]. Significantly fewer patients experienced an ocular adverse event with latanoprost in this trial. Hyperemia appears to be more of a cosmetic issue and is noted to generally be mild in severity and transient in nature.
- *Increased pigmentation* occurs more frequently with latanoprost (5-15%) than either bimatoprost (1-3%) or travoprost (1-4%). The pigmentation changes may be permanent.
- *Preservatives (Travatan versus Travatan Z)* – Products with preservatives that do not contain BAK are purported to have a favorable adverse event profile over products with BAK-based preservatives. A randomized trial in 700 patients evaluated the adverse events of the BAK-containing travoprost product (Travatan) with the non-BAK preservative formulation (Travatan Z). Hyperemia occurred in 9% of patients receiving Travatan, compared to 6.4% with Travatan Z (no p value provided) [Lewis 2007]. The adverse events in this trial were not serious and did not interrupt treatment.

iii) Drug discontinuations due to adverse effects

The prostaglandins are well tolerated. Discontinuation rates noted in package labeling due to conjunctival hyperemia were 3% for both travoprost and bimatoprost, and <1% for latanoprost. The discontinuation rates due to adverse events in one head to head trial were 0.7% with travoprost, 1.4% with bimatoprost, and zero with latanoprost [Parrish *et al.*, 2003].

b) Beta blockers

i) Serious adverse events – As a class, the ophthalmic beta blockers are associated with systemic adverse effects that limit their use for glaucoma, including bradycardia, arrhythmia, cardiac block, congestive heart failure, and bronchospasm. Betaxolol is the only β1 selective ophthalmic beta blocker; however bronchospasm has occurred in patients with asthma and chronic obstructive pulmonary disease. Both selective and non-selective beta blockers are contraindicated for use in patients with severe cardiovascular disease including sinus bradycardia, second and third degree heart block, cardiogenic shock, or patients with overt cardiac failure.

ii) Minor adverse events – Local adverse events of the beta blockers include stinging, itching, redness and blurred vision, which may be due to the preservative and pH of the solutions. Overall, stinging is most commonly associated with betaxolol and metipranolol. Timoptic maleate gel-forming solution is associated with transient blurry vision due to its thick consistency upon instillation.

Timolol maleate (Istalol) – A higher incidence of burning and stinging was associated with the once daily branded formulation of timolol maleate (Istalol) compared to timolol maleate (Timoptic, generics) in one trial (41.6% versus 22.9%) [Mundorf *et al.*, 2004].

c) Carbonic anhydrase inhibitors; and combinations with beta blockers

i) Serious adverse events – Brinzolamide and dorzolamide both have similar contraindications (hypersensitivity to the individual components). Brinzolamide/timolol (Cosopt) contains precautions regarding pulmonary and cardiovascular function seen with other ophthalmic beta blockers, due to the timolol component. Rare effects with dorzolamide include altered cornea endothelial cell function, renal calculi, and thrombocytopenia.

ii) Minor adverse effects – The most common adverse effects of the ophthalmic carbonic anhydrase inhibitors include local burning and stinging upon drug instillation, and taste perversion. In head-to-head-trials comparing brinzolamide with dorzolamide, dorzolamide was associated with a higher incidence of burning/stinging (12-16% versus 2-3%). The higher incidence of ocular discomfort with dorzolamide may be due to the acidic pH of the product (5.6) versus the more physiologic pH of brinzolamide (7.5). However, the ocular discomfort with dorzolamide appears transient, lasts about 10 seconds, is characterized as mild and diminishes with continued therapy [Stewart *et al.*, 2004]. The incidence of taste perversion appears similar between the two products, based on head-to-head clinical trials.

iii) Discontinuations due to adverse effects – It is difficult to determine differences in tolerability between brinzolamideand dorzolamide, as only a few patients discontinued therapy due to adverse events in the head-to-head clinical trials.

d) Alpha 2 adrenergics

i) Serious adverse effects – Both apraclonidine and brimonidine are contraindicated in patients with hypersensitivity to the individual agents, patients taking clonidine, and patients taking MAOIs. The alpha 2 adrenergics as a class may reduce pulse and blood pressure. Apraclonidine penetrates the blood brain barrier to a lesser extent than brimonidine, and is less likely to reduce heart rate and blood pressure.

ii) Minor adverse effects – Overall, the alpha 2 adrenergics are associated with a relatively high incidence of minor adverse events, including fatigue and local allergic reactions, compared to other glaucoma drug classes. As a class, the alpha 2 adrenergic agents can cause ocular intolerance (allergy leading to conjunctival erythema and potential periorbital infection) in 13% to 36% of patients. Apraclonidine can cause dry nose and mouth and upper eyelid retraction, and follicular conjunctivitis has occurred frequently. Brimonidine has a higher incidence of dry mouth (33%) than apraclonidine, but is associated with less frequent ocular side effects.

iii) Brimonidine formulations –There are three concentrations of brimonidine marketed; a 0.2% concentration with BAK as a preservative, and two products (0.15% and 0.1%) containing a purite preservative. There is only limited data comparing the safety differences between the three products. There are conflicting data as to whether brimonidine purite 0.15% (Alphagan P) causes less ocular irritation than brimonidine BAK 0.2%. A statistically significant 41% reduction in reports of allergic conjunctivitis, oral dryness, conjunctival hyperemia, and eye discharge with brimonidine purite 0.15% compared to brimonidine BAK 0.2% was found in one head-to-head trial, [Katz *et al.*, 2002], while another study noted no significant differences between the two drugs in the overall incidence of adverse events [Mundorf *et al.*, 2003)]. Indirect comparison of the trials does not suggest any difference in the incidence of discontinuation due to adverse drug reactions between the two agents.

Data from an unpublished study cited in product labeling found a significantly lower frequency of treatment-related adverse events with brimonidine purite 0.1% (Alphagan P) versus brimonidine BAK 0.2%. More patients (34%) discontinued treatment due to adverse events with brimonidine BAK 0.2% than with brimonidine purite 0.1% (21%).

e) Adrenergics, cholinergics, and cholinesterase inhibitors

i) Dipivefrin – Today dipivefrin is rarely used due to adverse effects such as conjunctival hyperemia, hypersensitivity and ocular irritation. It is contra-indicated in patients with narrow-angle glaucoma, since any dilation of the pupil may predispose the patient to an exacerbation of closed-angle glaucoma.

ii) Cholinergics – Retinal detachment and tearing may occur if the cholinergic drugs are used in patients with pre-existing retinal disease. Miotics may

also cause angle closure in patients with narrow angle glaucoma due to increased resistance to aqueous flow from the posterior to the anterior eye chamber.

Acetylcholine – Safety concerns with acetylcholine include infrequent corneal edema, corneal clouding, and corneal decompensation. Major adverse events are rare, but include bradycardia, hypotension, flushing, breathing difficulties, and sweating.

Carbachol – Carbachol is more potent than pilocarpine, and can induce significant adverse effects. Transient stinging and burning, in addition to corneal clouding have been reported. Brow ache is the most frequent patient-reported adverse effect, due to stimulation of the ciliary muscle, which exerts a physical pull on the trabecular mesh network. Older patients with cataracts often complain of dimmed vision caused by miosis. Severe but rare systemic effects include headache, sweating, epigastric distress, nausea, vomiting, and diarrhea.

Pilocarpine – Pilocarpine is associated with miosis or accommodative spasm, which may cause blurred vision and night blindness. Long-term use is limited by loss of visual field, due to the decreased amount of light entering the eye. Systemic adverse effects include atrioventricular block and other cardiovascular effects.

iii) Echothiophate – Echothiophate frequently causes blurred vision, brow ache, eyelid fasisculation, and watery eyes. Rarely, burning or stinging has been reported. Rare but serious adverse effects are similar to those of the miotics, but also include punctul stenosis of the nasolacrimal system. Organo-phosphate pesticides should be used with caution, as echothiophate activity may increase, raising the potential for adverse effects.

4) Other Factors

a) Prostaglandin analogs

Storage and stability – Latanoprost requires refrigeration prior to opening, to maintain a 36-month shelf life; it does not require refrigeration once opened. Bimatoprost and travoprost (Travatan, Travatan Z) do not require refrigeration.

Special populations – There are no differences between the prostaglandin analogs in their pregnancy category rating (all are pregnancy category C) or labeling for pediatric use (none are FDA-approved).

b) Beta blockers

Special populations – The ophthalmic beta blockers are rated a pregnancy category C. Timolol crosses into breast milk, so it should be avoided in lactating women. Safety and efficacy of ophthalmic beta-blockers have not been established in pediatrics. The majority of published information in children has been with timolol maleate. Topical application of timolol 0.5% can cause cardiac blockade in infants younger than 2 years of age.

Frequency of dosing – Patient convenience is an advantage of once daily ophthalmic beta blockers, particularly if multiple ophthalmic drugs are required. The branded timolol maleate product Istalol, and timolol maleate gel-forming solution are dosed once daily.

c) Carbonic anhydrase inhibitors; combinations with beta blockers

Dosing dispenser – The dosing dispenser of dorzolamide is specifically designed to deliver a controlled pre-measured drop, and will not operate unless the instructions are followed correctly.

Patient convenience – The primary advantage of the combination of dorzolamide with timolol (Cosopt) is patient convenience in reducing the number of bottles and daily ophthalmic drops required, potentially improving compliance.

d) Adrenergics, cholinergics, and cholinesterase inhibitors

i) Dipivefrin – The adrenergic dipivefrin still has a place in therapy as adjunctive therapy to beta blockers, pilocarpine and carbachol.

ii) Cholinergics – The cholinergics are usually reserved for patients who have not responded to other topical glaucoma treatments.

Pilocarpine – Pilocarpine is used to treat acute angle closure glaucoma and as a miotic during ocular surgery.

iii) Echothiophate – The cholinesterase inhibitor echothiophate has fallen out of favor, due to four times daily dosing, compared to newer agents.

Overall Clinical Effectiveness Conclusion – The P&T Committee concluded that:

1) *Prostaglandin analogs* – Bimatoprost, latanoprost, and travoprost all decrease IOP from baseline by 28% to 33%. A prospectively designed trial assessing efficacy of bimatoprost and travoprost found no difference in efficacy in African Americans; a sub-group analysis from a different trial reported decreased efficacy of latanoprost when compared to travoprost in African Americans versus non-African Americans. Latanoprost has the most favorable ocular adverse event profile of the three prostaglandin analogs, but requires refrigeration prior to opening. The non-BAK preservative found in the Travatan Z formulation of travoprost has not shown a major advantage in terms of ocular side effects, compared to the BAK-containing product Travatan.

2) *Beta blockers* – The IOP-lowering effects of timolol maleate (Timoptic, generics; Timoptic XE, generics), timolol hemihydrate, levobunolol, metipranolol and carteolol appear similar, based on several head-to-head studies. Timolol maleate solution (Timoptic, generics) and gel-forming solution reduce IOP by 20-35%. The Timoptic XE gel-forming solution has the advantage of once daily dosing, but is associated with transient blurred vision due to the consistency of the gel. There is no evidence that the timolol maleate product Istalol or the timolol hemihydrate product Betimol have additional clinical benefits over other timolol maleate products in IOP lowering or safety profiles. Betaxolol decreases IOP to a lesser

extent than timolol maleate; however, the β1 selectivity of betaxolol may be an advantage in patients with cardiac or pulmonary co-morbidities.

3) *Carbonic anhydrase inhibitors* – The IOP lowering effects of brinzolamideand dorzolamide appear similar. Dorzolamide/timolol (Cosopt) is the only combination product for glaucoma and offers a convenience to patients. Dorzolamide causes more local ocular irritation than brinzolamide; however, burning and stinging upon instillation last 10 seconds, diminish over time, and have not translated into a higher discontinuation rate due to adverse events.

4) *Alpha 2 adrenergics* – Apraclonidine is used primarily short-term following ocular surgery, while brimonidine is used chronically for glaucoma. Both apraclonidine and brimonidine lower IOP to a similar extent. For brimonidine, changing the BAK preservative (generic) to a purite preservative (Alphagan P) and reducing the concentration from 0.2% to 0.15% or 0.1% does not appear to affect efficacy. There are conflicting data as to whether brimonidine purite 0.15% (Alphagan P) causes less ocular irritation than brimonidine BAK 0.2% (generic). Brimonidine purite 0.1% (Alphagan P) may have an improved safety and tolerability profile compared to brimonidine BAK 0.1% (generic), but the one supportive study has not been published in a peer-reviewed journal.

5) *Adrenergics, cholinergics, and cholinesterase inhibitors* – The cholinergic pilocarpine is used for acute angle closure glaucoma and as a miotic agent during ocular surgery. Although not routinely used today, the adrenergic drug dipivefrin, the cholinergics acetylcholine and carbachol and the cholinesterase inhibitor echothiophate serve unique niches in therapy.

6) Based on clinical issues alone, there are no compelling reasons to classify any of the glaucoma drugs as non-formulary on the UF.

COMMITTEE ACTION: The P&T Committee voted (15 for, 0 opposed, 1 abstained, 1 absent) to accept the clinical effectiveness conclusions state above.

B. Ophthalmic Glaucoma Agents – Relative Cost Effectiveness

The P&T Committee evaluated the relative cost effectiveness of the ophthalmic glaucoma agents in relation to efficacy, safety, tolerability, and clinical outcomes of the other agents in the class. Information considered by the P&T Committee included, but was not limited to, sources of information listed in 32 CFR 199.21(e)(2).

The ophthalmic glaucoma agents were classified and compared within subgroups based on mechanism of action. The relative clinical effectiveness evaluation concluded that there was insufficient evidence to suggest that the glaucoma medications differed within subclasses in regards to efficacy, safety, tolerability, or clinical outcomes in the treatment of glaucoma. As a result, several CMAs were performed to determine the relative cost effectiveness of the agents within each subclass. The CMAs compared the weighted average cost per day of treatment for each drug product.

Results from the CMA of the prostaglandin subclass included three key findings: (1) travoprost (Travatan, Travatan Z) was most cost effective under a scenario where it was the sole agent on the uniform formulary; (2) Latanoprost and bimatoprost were most cost effective under a scenario where only two prostaglandin products were placed in the UF; and (3) an all on scenario (i.e., all three prostaglandin products included on the UF) was less cost effective than a scenario where at least one prostaglandin was designated non-formulary.

The results from the CMA of the topical beta-blockers showed that the majority of these products were cost effective. Only two products were identified as not cost effective in the beta-blocker subclass. Timolol hemihydrate and timolol maleate (Istalol) were both shown to be significantly more costly and no more effective than other agents in the subclass. Similarly, a comparison of the topical carbonic anhydrase inhibitors showed that brinzolamide was not cost effective compared to dorzolamide. All other medications in the remaining subclasses were determined to be cost effective relative to their comparators.

Based on the results of the clinical review and the pharmacoeconomic evaluations, a BIA of various formulary scenarios was conducted to estimate the influence of other factors associated with a UF decision (i.e., market share migration, switch costs, non-formulary cost-shares). The goal of the BIA was to aid the P&T Committee in determining which group of ophthalmic glaucoma agents would best meet the majority of the clinical needs of the DOD population at the lowest expected cost to the MHS.

COMMITTEE ACTION: The P&T Committee voted (15 for, 0 opposed, 1 abstained, 1 absent) to accept the cost effectiveness conclusions stated above.

C. Ophthalmic Glaucoma Agents – UF Recommendations

COMMITTEE ACTION: In view of the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of the ophthalmic glaucoma agents, and other relevant factors, the P&T Committee, based upon its collective professional judgment, voted (15 for, 0 opposed, 1 abstained, 1 absent) to recommend that latanoprost, bimatoprost, levobunolol, betaxolol (Betoptic, generics; Betoptic-S), carteolol, metipranolol, timolol maleate (Timoptic, generics), timolol maleate gel-forming solution (Timoptic XE, generics), brimonidine (generics; Alphagan P), apraclonidine, dorzolamide, dorzolamide/timolol (Cosopt), dipivefrin (Propine), acetylcholine (Miochol-E), carbachol (Isopto Carbachol), pilocarpine (Pilopine HS gel; Pilocar, generics), echothiophate (Phospholine Iodide) be maintained as formulary on the UF and that travoprost (Travatan, Travatan Z), timolol hemihydrate (Betimol), timolol maleate (Istalol) and brinzolamidebe classified as non-formulary under the UF.

D. Ophthalmic Glaucoma Agents – MN Criteria

Based on the clinical evaluation for travoprost (Travatan, Travatan Z), timolol hemihydrate, timolol maleate (Istalol) and brinzolamide, and the conditions for establishing MN for a non-formulary medication provided for in the UF rule, the P&T

Committee recommended the following general MN criteria for travoprost (Travatan, Travatan Z), timolol hemihydrate, timolol maleate (Istalol) and brinzolamide:

1) Formulary alternatives are contraindicated.
2) The patient has experienced or is likely to experience significant adverse effects from formulary alternatives.
3) Use of formulary alternatives has resulted in therapeutic failure.

COMMITTEE ACTION: The P&T Committee voted (14 for, 0 opposed, 1 abstained, 2 absent) to approve the MN criteria outlined above.

E. Ophthalmic Glaucoma Agents – UF Implementation Period

Because of the small number of unique utilizers affected (approximately 17,000 patients [15%] of approximately 111,000 unique utilizers at all three points of service), the P&T Committee recommended an effective date of the first Wednesday following a 90-day implementation period. The implementation period will begin immediately following approval by the Director, TMA.

MTFs will not be allowed to have travoprost (Travatan, Travatan Z), timolol hemihydrate, timolol maleate (Istalol) and brinzolamide on their local formularies. MTFs will be able to fill non-formulary requests for these agents only if both of the following conditions are met: 1) the prescription must be written by a MTF provider, and 2) MN is established. MTFs may (but are not required to) fill a prescription for a non-formulary glaucoma agent written by a non-MTF provider to whom the patient was referred, as long as MN has been established.

COMMITTEE ACTION: The P&T Committee recommended (15 for, 0 opposed, 1 abstained, 1 absent) an effective date of the first Wednesday following a 90-day implementation period. The implementation period will begin immediately following the approval by the Director, TMA.

F. Ophthalmic Glaucoma Agents – BCF Review and Recommendations – The P&T Committee considered the BCF status of the ophthalmic glaucoma agents. Based on the results of the clinical and economic evaluations presented, the P&T Committee voted (15 for, 0 opposed, 1 abstained, and 1 absent) to recommend that the BCF include latanoprost; brimonidine, excluding the 0.1% strength; timolol maleate (Timoptic, generics) 0.25% and 0.5%; timolol maleate gel-forming solution 0.25% and 0.5%; and pilocarpine.

9. DRUG CLASS REVIEW – MAOI ANTIDEPRESSANTS

The P&T Committee evaluated the relative clinical effectiveness and cost effectiveness of the MAOI antidepressants marketed in the U.S. The drugs in the MAOI antidepressant class include three oral agents, isocarboxazid (Marplan), phenelzine (Nardil), and tranylcypromine (Parnate, generics); and one transdermal patch, selegiline (Emsam). Tranylcypromine is the only drug in the MAOI antidepressant class available in a generic formulation. All of the drugs are available in oral dosage forms; however, oral selegiline capsules are excluded from the review, since they are indicated for use in Parkinson's disease and not depression. The three oral MAOI antidepressants were first introduced to

the market in the early 1960s, while transdermal selegiline was launched in 2006. The MAOI antidepressants accounted for approximately $283,000 dollars spent in FY 2006 wresp, which amounts to less than 1% of total MHS expenditures for all antidepressant drug classes.

A. MAOI Antidepressants – Relative Clinical Effectiveness

The P&T Committee evaluated the relative clinical effectiveness of the MAOI antidepressant agents currently marketed in the U.S. Information regarding the safety, effectiveness, and clinical outcomes of these drugs was considered. The clinical review included, but was not limited to, the requirements stated in the UF Rule, 32 CFR 199.21(e)(1). The P&T Committee was advised that there is a statutory presumption that pharmaceutical agents in a therapeutic class are clinically effective and should be included on the UF, unless the P&T Committee finds by a majority vote that a pharmaceutical agent does not have a significant, clinically meaningful therapeutic advantage in terms of safety, effectiveness, or clinical outcome over the other pharmaceutical agents included on the UF in that therapeutic class.

1) Pharmacology

There are two MAOI enzymes. Inhibition of MAO-B enzyme in the CNS leads to decreased metabolism of norepinephrine, dopamine and serotonin. Inhibition of MAO-A enzyme in the gastrointestinal tract results in decreased catabolism of tyramine, which can increase blood pressure. Patients taking MAOI anti-depressants who do not restrict dietary sources of tyramine can potentially develop hypertensive crisis. Theoretically, administering an MAOI anti-depressant via the transdermal route would obviate the need for strict dietary precautions.

2) Efficacy for Atypical Depression and Major Depressive Disorder (MDD)

a) FDA-approved indications

The three oral MAOI antidepressants, isocarboxazid, phenelzine, and tranylcypromine, are FDA-approved to treat either atypical depression or MDD. The selegiline transdermal patch is indicated only for treatment of MDD.

b) Efficacy measures

The Hamilton Rating Scale for Depression (HAM-D) is the most widely used observer-rated scale that assesses the symptoms and severity of depression. In efficacy trials for the MAOI antidepressants, a 50% reduction in the HAM-D from baseline was considered a response to treatment. Remission refers to reduction in the HAM-D score below a specific cut-off score.

c) Efficacy of oral MAOI antidepressants

i) Meta-analysis – One meta-analysis [Thase *et al.*, 1995] evaluated 55 RCTs (published from 1959 through 1992) that focused on depressive disorders in adults in the outpatient setting. The trials evaluated the efficacy of isocarboxazid, phenelzine, and tranylcypromine.

There were no apparent differences in the overall efficacy between isocarboxazid (60% ± 7%), phenelzine (58% ± 4%), and tranylcypromine (53% ± 12%). Limitations to the meta-analysis included differences in trial methodologies and patient populations between trials and the fact that evaluated studies were from approximately 30 years ago.

ii) Head-to-head clinical trial – One head-to-head trial compared the efficacy of phenelzine and tranylcypromine in 77 inpatients with antidepressant-refractory depression [Birkenhager *et al.*, 2004]. A response to therapy occurred in 44% (17/39) of the patients receiving tranylcypromine, and 47 % (18/38) of the patients randomized to phenelzine (p=0.82). Only 18% (7/39) of the tranylcypromine-treated patients and 11% (4/38) of the phenelzine-treated patients met criteria for remission (p=0.52). This trial had limited power to detect a difference between the two drugs and was conducted in the inpatient setting.

d) Efficacy of transdermal selegiline

Three published placebo-controlled trials lasting six to eight weeks and one open-label trial lasting 52 weeks evaluate the efficacy of the transdermal selegiline formulation. There are no comparative trials evaluating efficacy differences between transdermal selegiline and any of the three oral MAOI antidepressant or other antidepressants (e.g., TCAs, SSRIs).

i) Placebo-controlled trials – In the first trial, a response to therapy occurred in 38% of patients receiving transdermal selegiline 6 mg/24 hr, compared to 23% receiving placebo (p=0.01); remission occurred in 23% of the patients treated with the patch compared to 11 % with placebo (p=0.05) [Bodkin *et al.*, 2002]. In the second trial, response rates ranged from 32% to 33% with transdermal selegiline 6 mg/24 hr, versus 21% to 30% with placebo [Amsterdam *et al.*, 2003]. In the third trial [Fieger *et al.*, 2006], the response rate was 40% with transdermal selegiline (flexible dosing up to 12 mg/24 hr) versus 30% with placebo (p value not significant)

ii) Open label extension trial – In an open label extension trial enrolling 600 patients who had previously responded to transdermal selegiline, 17% of patients randomized to the patch relapsed after one year, compared to 31% of placebo-treated patients (p=0.003).

e) Clinical efficacy conclusion

A meta-analysis comparing the three oral MAOIs reported similar overall efficacy rates of 58% with phenelzine, 60% with isocarboxazid, and 53% with tranylcypromine in the outpatient setting. One trial conducted in an inpatient population found no statistically significant difference between phenelzine and tranylcypromine in response or remission rates. For transdermal selegiline, three placebo controlled trials are available. The response rates with transdermal selegiline ranged from 30% to 40%, compared to 21% to 30% with placebo.

3) Safety and Tolerability

a) *Minor adverse events* – The most common adverse effects of the oral MAOI antidepressants are orthostatic hypotension, dizziness, edema, tremor, insomnia, mydriasis, and anorgasmia. There are no data to suggest that one oral MAOI antidepressant is more likely than another to be associated with minor adverse effects.

Mild to moderate local irritation at the application site occurred in 15% to 36% of patients receiving transdermal selegiline in the placebo controlled trials. As with the oral MAOI antidepressants, insomnia and orthostatic hypotension are also concerns, with higher incidences reported with the 9 mg/24 hr and 12 mg/24 hr strengths.

b) *Serious adverse events* – As a class, the MAOI antidepressants have the potential for causing serotonin syndrome when administered with other serotonergic drugs or when dietary precautions are not followed. Deaths have been reported with the oral MAOI antidepressants due to both drug-drug and drug-food interactions. The MAOI antidepressants are considered third-line agents due to their adverse effect profile. To date there have been no deaths or other life-threatening events including hypertensive crisis attributed to transdermal selegiline in the controlled setting of the clinical trials.

c) *Drug-food interactions* – Consumption of tyramine-containing foods (e.g., aged meats, aged cheeses) and beverages (e.g., non-pasteurized beers) while taking any MAOI may result in hypertensive crisis. The lowest dosage strength of transdermal selegiline (6 mg/24 hr) is the only dosage where dietary tyramine restrictions are not required in the product labeling. A tyramine-restricted diet is required with all oral MAOIs and with the 9 mg/24 hr and 12 mg/24 hr strengths of transdermal selegiline. Most patients are likely to require the higher strengths of transdermal selegiline for MDD.

d) *Drug-drug interactions* – As a class, the oral MAOI antidepressants are associated with several well known and clinically important drug-drug interactions. The same extensive list of drug-drug interactions also applies to transdermal selegiline. Concomitant use of any MAOI antidepressant, including transdermal selegiline, is contraindicated with meperidine, tramadol, methadone, propoxyphene, dextromethorphan, cyclobenzaprine, carbamazepine, other MAOIs, SSRIs, and amphetamine derivatives.

e) *Withdrawal due to adverse events* – Differences in tolerability profiles between the three oral MAOI antidepressants are difficult to determine, as the available clinical trials used less rigorous study design than is standard today.

In the three short-term (6- to 8-week) placebo controlled trials evaluating transdermal selegiline, 6% (23/370) of patients randomized to the patch discontinued therapy due to an adverse event, compared to 4% (16/373) of subjects in the placebo groups. Application site reactions were the most common reason for discontinuation. In the 52-week open label trial,

discontinuation rates due to application site reactions were 15% with transdermal selegiline versus 4% with placebo.

f) Safety and tolerability conclusion – The MAOI antidepressants as a class are associated with several serious adverse events. Hypertensive crisis and risk of death due to dietary and drug-drug interactions are well-publicized. In the placebo controlled trials with transdermal selegiline, a high incidence of local patch irritation was reported. Dietary restrictions are required with all oral MAOIs and with the 9 mg/24 hr and 12 mg/24 hr strengths of transdermal selegiline. There are no head-to-head trials comparing the safety and tolerability profiles of transdermal selegiline versus the oral MAOIs.

4) Other factors

a) Available dosage formulations – Transdermal selegiline is the only MAOI antidepressant available in a non-oral dosage formulation. Transdermal selegiline would be preferred over the oral MAOI antidepressants in patients with dysphagia.

b) Dosing frequency – Transdermal selegiline and tranylcypromine are the only MAOI antidepressants that are dosed once daily. Isocarboxazid and phenelzine require dosing twice to three times daily.

c) Potential for off-label uses – The oral MAOI antidepressants have many off-label uses other than depression, including panic disorder and social anxiety disorder. Oral selegiline is currently used in conjunction with carbidopa-levodopa in Parkinson's Disease. Transdermal selegiline is currently undergoing Phase II trials to evaluate efficacy for depression in patients with Parkinson's Disease, but no peer-reviewed studies have been published.

d) Pregnancy – The oral MAOI antidepressants and transdermal selegiline are contraindicated for use during pregnancy; however, there are published reports of the use of phenelzine and tranylcypromine in pregnant patients with severe depression.

e) Pediatrics – The three oral MAOI antidepressants and transdermal selegiline are not approved for use in children younger than 16 years of age.

f) Other factors conclusion – There are only minor differences in other factors for the MAOIs, including dosing frequency, availability of non-oral dosage formulations, and potential for off-label uses.

MAOI Antidepressant Overall Clinical Effectiveness Conclusion – The P&T Committee concluded that:

1) The oral MAOI antidepressants isocarboxazid, phenelzine, and tranylcypromine have been marketed for several decades, but have been replaced by newer drug classes (e.g., SSRIs) with more favorable adverse event profiles.

2) Transdermal selegiline is the newest MAOI antidepressant marketed. The non-oral formulation was developed to reduce the risk of hypertensive crisis from tyramine.

3) There do not appear to be major differences in clinical efficacy between the three oral MAOIs when used for depression, based on the results of one meta-analysis showing response rates ranging between 53% to 61%, and one inpatient clinical trial.

4) Overall, response rates ranging from 27% to 30% were reported with transdermal selegiline in three placebo controlled trials. There are no clinical trials directly comparing the oral MAOI antidepressants with transdermal selegiline However, there are no data to suggest that treatment with transdermal selegiline would result in improved response rates compared to the oral MAOI antidepressants.

5) The MAOI antidepressants have a safety profile that is well recognized in terms of drug-drug and drug-food interactions, and these adverse events also apply to transdermal selegiline. Local application site reactions are common with transdermal selegiline.

6) The purported benefits of transdermal selegiline in terms of loosened dietary tyramine restrictions have only been shown clinically with the lowest dose (6 mg/24 hr). Dietary precautions are required with oral MAOIs and with the 9 mg/24 hr and 12 mg/24 hr dosages of transdermal selegiline.

7) Off-label usage of transdermal selegiline is anticipated for treating patients with Parkinson's Disease.

8) The primary advantage of transdermal selegiline is for patients unable to swallow oral medications and require a once-daily dosage formulation.

9) There is insufficient evidence to determine whether transdermal selegiline represents a therapeutic advance over isocarboxazid, phenelzine and tranylcypromine.

10) Based on clinical issues alone, there are no reasons to designate any of the MAOIs (phenelzine, isocarboxazid, or tranylcypromine, and transdermal selegiline) as non-formulary on the Uniform Formulary.

COMMITTEE ACTION – The P&T Committee voted (16 for, 0 opposed, 1 abstained, 0 absent) to accept the clinical effectiveness conclusions stated above.

B. MAOI Antidepressants – Relative Cost Effectiveness

The P&T Committee evaluated the relative cost effectiveness of the MAOI antidepressants in relation to the efficacy, safety, tolerability, and clinical outcomes of the other agents in the class. Information considered by the P&T Committee included but was not limited to sources of information listed in 32 CFR 199.21(e) (2). Given the overall clinical conclusion that the agents within the MAOI class have similar relative clinical effectiveness, a CMA was employed to assess the relative cost effectiveness of the agents within this therapeutic class. The agents were evaluated on their weighted average cost per day of therapy across all three points of service.

Results of the CMA for the MAOI class showed that:

1) Among the oral agents, phenelzine was the most cost effective agent, followed closely by tranylcypromine and isocarboxazid.

2) Transdermal selegiline was the least cost effective MAOI for the treatment of depression. The weighted average cost per day of treatment with transdermal selegiline was four-fold higher than the most costly oral MAOI, isocarboxazid.

Cost Effectiveness Conclusion

1) The oral MAOIs demonstrate similar relative cost effectiveness, with phenelzine as the most cost effective agent.

2) Transdermal selegiline is not cost effective relative to the other agents in the class in the treatment of depression and provides no clinically meaningful therapeutic advantage to justify the increased cost.

COMMITTEE ACTION: The P&T Committee voted (15 for, 0 opposed, 0 abstained, 2 absent) to accept the cost effectiveness conclusions stated above.

C. MAOI Antidepressants – UF Recommendations

COMMITTEE ACTION: Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of the MAOIs, and other relevant factors, the P&T Committee, based upon its collective professional judgment, voted (14 for, 0 opposed, 1 abstained, 2 absent) to recommend that phenelzine, tranylcypromine and isocarboxazid be maintained as formulary on the UF and that transdermal selegiline be classified as non-formulary under the UF.

D. MAOI Antidepressants – MN Criteria

Based on the clinical evaluation for transdermal selegiline and the conditions for establishing MN for a non-formulary medication provided for in the UF rule, the P&T Committee recommended the following general MN criteria for transdermal selegiline:

1) Use of formulary alternatives is contraindicated.

2) The patient has experienced or is likely to experience significant adverse effects from formulary alternatives.

3) Use of formulary alternatives has resulted in therapeutic failure.

4) The patient previously responded to a *non-formulary* pharmaceutical agent and changing to a formulary pharmaceutical agent would incur an unacceptable clinical risk.

5) No formulary alternative is available.

The P&T Committee noted that criterion #5 would only apply to patients unable to take oral medications.

COMMITTEE ACTION: The P&T Committee voted (15 for, 0 opposed, 1 abstained, 2 absent) to approve the MN criteria outlined above.

E. MAOI Antidepressants – UF Implementation Period

Because of the small number of unique utilizers affected (approximately 135 patients per quarter at all three points of service), the P&T Committee recommended an effective date of the first Wednesday following a 90-day implementation period. The

implementation period will begin immediately following approval by the Director, TMA.

MTFs will not be allowed to have transdermal selegiline on their local formularies. MTFs will be able to fill non-formulary requests for this agent only if both of the following conditions are met: 1) the prescription must be written by a MTF provider, and 2) MN is established. MTFs may (but are not required to) fill a prescription for a non-formulary MAOI antidepressant agent written by a non-MTF provider to whom the patient was referred, as long as MN has been established.

COMMITTEE ACTION: The P&T Committee recommended (14 for, 0 opposed, 1 abstained, 2 absent) an effective date of the first Wednesday following a 90-day implementation period. The implementation period will begin immediately following the approval by the Director, TMA.

F. MAOI Antidepressant – ECF Review and Recommendations

The P&T Committee had previously determined at the November 2006 P&T Committee meeting that one MAOI antidepressant should be added to the ECF based on the clinical and cost effectiveness review. As a result of the clinical and economic evaluations presented, the P&T Committee recommended that phenelzine be classified as the ECF agent. Phenelzine was determined to be the most cost effective MAOI and currently has the greatest utilization across the MHS.

COMMITTEE ACTION: The P&T Committee voted (14 for, 0 opposed, 1 abstained, 2 absent) to recommend phenelzine be classified as the ECF agent.

10. CLASS OVERVIEWS

Portions of the clinical reviews for the ophthalmic non-steroidal anti-inflammatory agents (Ophthalmic NSAIDs) and erythropoiesis stimulating agents (ESAs) were presented to the P&T Committee.

The P&T Committee provided expert opinion regarding those clinical outcomes considered most important for the PEC to use in completing the clinical effectiveness review and developing the appropriate cost effectiveness models. The clinical and economic analyses of these classes will be completed during the May 2007 or August 2007 meetings; no action is necessary.

11. ADJOURNMENT

The second day of the meeting adjourned at 1430 hours on 14 February 2007. The next meeting will be 13-15 May 2007.

ADHD = Attention Deficit Hyperactivity Disorder; ARBs = Angiotensin Receptor Blockers; ACE Inhibitors = Angiotensin Converting Enzyme Inhibitors; BPH = Benign Prostatic Hypertrophy; CCBs = Calcium Channel Blockers; EE = ethinyl estradiol; GI = gastrointestinal; GABA = gamma-aminobutyric acid; H2 = Histamine-2 receptor; HCTZ = hydrochlorothiazide; MS-DMDs = Multiple Sclerosis Disease-Modifying Drugs; OABs = Overactive Bladder Medications; PDE-5 Inhibitors = Phosphodiesterase-5 inhibitors; PPIs = Proton Pump Inhibitors; TZDs = thiazolidinediones

*The topical antifungal drug class excludes vaginal products and products for onychomycosis (e.g., ciclopirox topical solution [Penlac])

Appendix B – Table 2. Newly Approved Drugs. February 2007 DoD P&T Committee Meeting

Medication (Brand name; manufacturer) mechanism of action	**FDA Approval Date & FDA-Approved Indications**	**Committee Recommendation**
Sitagliptin phosphate tablets (Januvia ;Merck) Oral hypoglycemic drug (dipeptidyl peptidase IV [DPP4] inhibitor)	Oct 06 (launched Nov 06) ▪ For use as monotherapy as an adjunct to diet and exercise to improve glycemic control in patients with type 2 diabetes mellitus ▪ For use in patients with type 2 diabetes mellitus to improve glycemic control in combination with metformin, or a thiazolidinediones when the single agent alone, with diet and exercise, does not provide adequate glycemic control. ▪ Should not be used in patients with type 1 diabetes or for the treatment of diabetic ketoacidosis, as it would not be effective in these settings	No UF recommendation at this meeting. Consideration of UF status deferred until oral hypoglycemic drugs are reviewed; UF review not anticipated for 12 months.
Paliperidone extended release tablets (Invega; Janssen/ALZA)) Atypical antipsychotic	Dec 06 (launched Jan 07) ▪ Treatment of schizophrenia ▪ Efficacy in acute treatment of schizophrenia established in three 6-week, placebo controlled, fixed-dose trials in subjects with schizophrenia. ▪ Efficacy not evaluated in placebo-controlled trials for longer than six weeks; physicians electing to use paliperidone for extended periods should periodically re-evaluate long-term usefulness	No UF recommendation at this meeting. Consideration of UF status deferred until atypical antipsychotics are reviewed; UF review not anticipated for 12 months.

DECISION PAPER

DEPARTMENT OF DEFENSE

PHARMACY AND THERAPEUTICS COMMITTEE RECOMMENDATIONS

November 2006

1. **CONVENING**
2. **ATTENDING**
3. **REVIEW MINUTES OF LAST MEETING**
4. **ITEMS FOR INFORMATION**
5. **REVIEW OF RECENTLY APPROVED AGENTS**

Recently Approved Agents in Classes Not Yet Reviewed for the Uniform Formulary (UF): The P&T Committee was briefed on four new drugs approved by the Food and Drug Administration (FDA) that did not fall under drug classes previously reviewed for UF consideration. The committee discussed the need for quantity limits and prior authorization (PA) for two of the new drugs, human insulin inhalation powder (Exubera) and fentanyl buccal tablets (Fentora); there are existing quantity limits for other inhaled products and fentanyl lozenges. No recommendations were made for human insulin inhalation powder, as typical dosage requirements and utilization are unclear at this time. The Committee deferred a decision on quantity limits for fentanyl buccal tablets until the narcotic analgesic class is reviewed at an upcoming meeting.

Contraceptive Agents 30/10 mcg ethinyl estradiol (EE)/0.15 mg levonorgestrel for extended use, (Seasonique), and 20 mcg ethinyl estradiol (EE)/1 mg norethindrone acetate – 24 day regimen, (Loestrin 24 Fe).

Background: Two new contraceptive products, Seasonique and Loestrin 24 Fe, have been marketed since the contraceptive drug class was reviewed in May 2006.

Seasonique - Seasonique is a monophasic oral contraceptive with 30 mcg of EE specifically packaged and labeled for extended cycle use (84 days of 30 mcg EE/0.15 mg levonorgestrel, followed by seven days of low-dose estrogen [10 mcg EE]). The rationale for providing seven days of 10 mcg EE instead of placebo is to reduce symptoms associated with estrogen withdrawal, including dysmenorrhea, menstrual migraine, and premenstrual syndrome, although this has not been evaluated in a prospective, randomized, controlled trial.

The difference between Seasonale, a non-formulary (third) tier agent, and Seasonique is the substitution of seven low-dose estrogen (10 mcg EE) tablets in Seasonique for the seven placebo tablets in Seasonale. For this reason, Seasonique's regimen cannot be exactly duplicated by using conventional packages of Nordette or its equivalents and discarding unneeded placebo tablets, unlike Seasonale. With respect to efficacy in preventing pregnancy, there is no reason to believe that Seasonique would differ from other similar oral contraceptives.

Loestrin 24 FE: Loestrin 24 Fe is a monophasic oral contraceptive product with 20 mcg EE packaged as a 24-day regimen (24 days of 20 mcg EE /1 mg norethindrone followed by four days of placebo tablets).

The rationale for a 24- rather than a 21-day regimen is to decrease the number of bleeding days and reduce adverse events associated with estrogen withdrawal. It is also possible that a longer regimen would increase the safety margin for contraceptive effectiveness with low estrogen products; however, there is no supporting clinical evidence. An alternative using conventionally packaged Loestrin Fe 1/20 that may accomplish the same general goal would be to simply start a new package early.

Relative Clinical Effectiveness Conclusion: The Committee concluded (15 for, 0 opposed, 0 abstained, 2 absent) that Seasonique and Loestrin 24 Fe do not have a significant, clinically meaningful therapeutic advantage in terms of safety, effectiveness, or clinical outcome, over the other oral contraceptives included on the UF.

Relative Cost Effectiveness Conclusion: Cost minimization analysis (CMA) showed that Seasonique is less cost-effective on a per cycle basis than all UF oral contraceptives containing 30 mcg EE and Loestrin 24 Fe is less cost-effective on a per cycle basis than all UF oral contraceptives containing 20 mcg EE. Based on the results of the CMAs and other clinical and cost considerations, the Committee concluded (15 for, 0 opposed, 0 abstained, 2 absent) that Seasonique and Loestrin 24 Fe are substantially more costly than other oral contraceptives containing 30 mcg EE or 20 mcg EE included on the UF.

A. COMMITTEE ACTION: UF RECOMMENDATION – Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations for Seasonique and Loestrin 24 Fe, and other relevant factors, the P&T Committee, based upon its collective professional judgment, voted (15 for, 0 opposed, 0 abstained, 2 absent) to recommend that Seasonique and Loestrin 24 Fe be classified as non-formulary under the UF. (See paragraphs 5B1, 5B2 and 5B3 on pages 14-16 of the P&T Committee minutes).

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

B. COMMITTEE ACTION: MEDICAL NECESSITY CRITERIA – Based on the clinical evaluation of Seasonique and Loestrin 24 Fe and the conditions for establishing medical necessity of a non-formulary medication provided for in the UF rule, the P&T Committee recommended (15 for, 0 opposed, 0 abstained, 2 absent) medical necessity criteria for the contraceptive agents. (See paragraph 5B4 on page 17 of the P&T Committee minutes for the criteria).

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

C. COMMITTEE ACTION: IMPLEMENTATION PERIOD – The P&T Committee voted (15 for, 0 opposed, 0 abstained, 2 absent) to recommend an effective date of the first Wednesday following a 60-day implementation period. The implementation period will begin immediately following approval by the Director, TMA. (See paragraph 5B5 on page 17 of the P&T Committee minutes for rationale).

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows: *"Implement January 24, 2007"*

Topical antifungal agents – 0.25% miconazole, 15% zinc oxide, 81.35% white petrolatum ointment (Vusion)

Background: The topical antifungal agents were reviewed by the Committee in Aug 2005. A new ointment containing 0.25% miconazole, 15% zinc oxide, and 81.35% white petrolatum (Vusion) has been approved by the FDA. Vusion contains a much lower concentration of miconazole than other prescription and OTC miconazole products (0.25% vs. 2%) and is only available in an ointment formulation.

Vusion is specifically labeled for the adjunctive treatment of diaper dermatitis only when complicated by microscopically-documented candidiasis in immunocompetent pediatric patients four weeks and older.

Relative Clinical Effectiveness Conclusion: The P&T Committee voted (15 for, 0 opposed, 0 abstained, 2 absent) that although Vusion is labeled for a specific type of diaper dermatitis in infants as young as four weeks of age, it does not have a significant, clinically meaningful therapeutic advantage in terms of safety, effectiveness, or clinical outcome, over the other topical antifungals included on the UF.

Relative Cost Effectiveness Conclusion: CMA showed that Vusion is the least cost-effective of all comparators, including other antifungals commonly used for diaper rash, when analyzed on a cost per utilizer basis. Based on the results of the CMA and other clinical and cost considerations, the P&T Committee voted (15 for, 0 opposed, 0 abstained, 2 absent) that Vusion is substantially more costly than other antifungals commonly used for the treatment of the same condition.

A. COMMITTEE ACTION: UF RECOMMENDATION – Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determination for Vusion, and other relevant factors, the P&T Committee, based upon its collective professional judgment, voted (15 for, 0 opposed, 0 abstained, 2 absent) to recommend that Vusion be classified as non-formulary under the UF. (See paragraphs 5C1, 5C2 and 5C3 on pages 17-19 of the P&T Committee minutes).

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

B. COMMITTEE ACTION: MEDICAL NECESSITY CRITERIA – Based on the clinical evaluation of Vusion and the conditions for establishing medical necessity of a non-formulary medication provided for in the UF rule, the P&T Committee recommended (15 for, 0 opposed, 0 abstained, 2 absent) medical necessity criteria for Vusion. (See paragraph 5C4 on page 19 of the P&T Committee minutes for the criteria).

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

C. COMMITTEE ACTION: IMPLEMENTATION PERIOD – The P&T Committee voted (15 for, 0 opposed, 0 abstained, 2 absent) to recommend an effective date of the first Wednesday following a 60-day implementation period. The implementation period will begin immediately following approval by the Director, TMA. (See paragraph 5C5 on page 19 of the P&T Committee minutes for rationale).

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows: *"Implement in 30 days."*

Antiemetic Agents - Nabilone (Cesamet)

Background: The Committee previously reviewed the antiemetic agents in May 2006. Nabilone is a synthetic cannabinoid antiemetic similar to dronabinol. Nabilone is indicated for treatment of chemotherapy-induced nausea and vomiting when conventional antiemetics have failed. There are no published clinical trials comparing nabilone with dronabinol, or with the 5-hydroxytryptamine-3 (5-HT3) antagonists.

Relative Clinical Effectiveness Conclusion: The P&T Committee voted (15 for, 0 opposed, 0 abstained, 2 absent) that while nabilone offers a slight convenience of dosing frequency compared to dronabinol, it does not have a significant, clinically meaningful therapeutic advantage in terms of safety, effectiveness, or clinical outcomes over the other antiemetics included on the UF.

Relative Cost Effectiveness Conclusion: CMA showed that nabilone has a cost-effectiveness profile that is similar to dronabinol. Based on the results of the CMA and other clinical and cost considerations, the P&T Committee voted (15 for, 0 opposed, 0 abstained, 2 absent) that nabilone is comparable in cost to dronabinol, a similar cannabinoid antiemetic included on the UF.

A. COMMITTEE ACTION: UF RECOMMENDATION – Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations for nabilone, and other relevant factors, the P&T Committee, based upon its collective professional judgment, voted (15 for, 0 opposed, 0 abstained, 2 absent) to recommend that nabilone be classified as formulary on the UF.

(See paragraphs 5D1, 5D2 and 5D3 on pages 20-21 of the P&T Committee minutes).

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

6. DRUG CLASS REVIEW – OLDER SEDATIVE HYPNOTICS (SED-2s)

The P&T Committee evaluated the relative clinical effectiveness of the Older Sedative/Hypnotic (SED-2) Medications. The SED-2 drug class is comprised of five hypnotic benzodiazepines: estazolam, flurazepam, quazepam, temazepam, and triazolam; two barbiturate hypnotics: butabarbital and secobarbital; and one nonbarbiturate hypnotic agent: chloral hydrate. All eight of these drugs have been marketed for a number of years, and all but quazepam, butabarbital, and two less commonly used strengths of temazepam are available in generic formulations. The SED-2 drug class accounted for $2.5 million in Military Health System (MHS) expenditures for the period Aug 2005 to July 2006 and is ranked #165 in terms of total expenditures during that time period.

Relative Clinical Effectiveness Conclusion: The Committee voted (15 for, 0 opposed, 0 abstained, 2 absent) that:

1) The five hypnotic benzodiazepines (estazolam, flurazepam, quazepam, temazepam, and triazolam) are widely considered interchangeable for the treatment of short-term insomnia when used in equipotent doses, despite differences in onset and duration of action.
2) Temazepam is the most desirable benzodiazepine in the SED-2 drug class, based on clinical factors (duration of action, tolerance to therapeutic effects, adverse effect profile).
3) The hypnotic barbiturates, secobarbital and butabarbital, have fallen out of favor compared to newer therapies, primarily due to safety concerns, and are infrequently utilized at any MHS point of service.
4) Chloral hydrate appears to have a unique niche in the setting of outpatient pediatric sedation.
5) There are no clinical reasons to justify designating any of the SED-2s as non-formulary under the UF.

Relative Cost Effectiveness Conclusion: Based on the results of the CMA and other clinical and cost considerations, the P&T Committee voted (15 for, 0 opposed, 0 abstained, 2 absent) that:

1) Secobarbital, chloral hydrate, flurazepam, temazepam 15 and 30 mg, estazolam, and triazolam have similar relative cost-effectiveness.
2) Butabarbital, quazepam, and temazepam 7.5 and 22.5mg are more costly relative to the other agents in the class, but placing these agents in the non-formulary tier of the UF would achieve little savings due to current and projected low utilization.

A. COMMITTEE ACTION: UF RECOMMENDATION **-** Taking into consideration the conclusions from the relative clinical effectiveness and relative cost

effectiveness determinations for the SED-2s, and other relevant factors, the P&T Committee, based upon its collective professional judgment, voted (15 for, 0 opposed, 0 abstained, 2 absent) to recommend that estazolam, flurazepam, quazepam, temazepam, triazolam, butabarbital, secobarbital, and chloral hydrate be maintained as formulary on the UF, and that none of the SED-2s be classified as non-formulary under the UF. (See paragraphs 6A, 6B and 6C on pages 22-24 of the P&T Committee minutes).

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

B. COMMITTEE ACTION: BASIC CORE FORMULARY (BCF) RECOMMENDATION – Based on the relative clinical effectiveness and cost effectiveness analyses, the P&T Committee voted (15 for, 0 opposed, 0 abstained, 2 absent) to recommend retaining the generically available strengths of temazepam (15 mg and 30 mg) as the BCF selections in this class, excluding the 7.5 mg and 22.5 mg proprietary dosage strengths. (See paragraph 6F on page 25 of the P&T Committee minutes for rationale).

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

7. DRUG CLASS REVIEW – ATTENTION-DEFICIT / HYPERACTIVITY DISORDER AND NARCOLEPSY AGENTS

The drugs in the Attention-Deficit / Hyperactivity Disorder (ADHD) and Narcolepsy Agents class are comprised of the following: for ADHD, there is one non-stimulant: atomoxetine (Strattera) and five stimulant compounds: methylphenidate, mixed amphetamine salts, dexmethylphenidate, dextroamphetamine, and methamphetamine; for narcolepsy, there are two drugs: modafinil (Provigil) and sodium oxybate (Xyrem). The ADHD and Narcolepsy Agents accounted for approximately $84.5 million dollars in MHS expenditures for Fiscal Year (FY) 2006 and are ranked #16 in terms of total expenditures during that time period.

Relative Clinical Effectiveness Conclusion: The P&T Committee voted (16 for, 0 opposed, 0 abstained, 1 absent) to accept the following:

1) For ADHD, interpretation of the data is limited due to the poor quality of studies, limited number of comparator trials, varying rating scales used, small number of patients enrolled, and short study duration.

2) There is no evidence to suggest a difference in efficacy between immediate release (IR) formulations of methylphenidate, dextroamphetamine, dexmethylphenidate, and mixed amphetamine salts.

3) The overall efficacy of the once daily methylphenidate formulations appears similar based on a few small studies, but differences exist in reported outcomes at specific times of the day, due to the individual release mechanisms of the

products. Methylphenidate 30% IR/70% extended release (ER) (Metadate CD) and methylphenidate SODAS (Ritalin LA) are eight- to nine-hour products, while methylphenidate OROS (Concerta), dexmethylphenidate SODAS (Focalin XR), and methylphenidate transdermal system (Daytrana) are 12-hour products.

4) Mixed amphetamine salts extended release (ER) (Adderall XR) appears to have similar efficacy to methylphenidate OROS (Concerta), based on one small study.

5) The efficacy of atomoxetine appears to be inferior to the stimulants, but it is the only non-stimulant available in the ADHD class.

6) Between 40% and 80% of patients who do not respond to one type of stimulant (methylphenidate products vs. amphetamine products) may respond to the other.

7) The adverse events and warnings of the stimulants are well-recognized and are similar between products.

8) The methylphenidate transdermal system can cause significant dermatological adverse events, which can lead to sensitization to oral products.

9) Atomoxetine remains the only alternative for patients who cannot tolerate stimulants, despite its association with an increased risk of hepatotoxicity and suicidal ideation.

10) Several products can be sprinkled on food for patients with swallowing difficulties.

11) Responders to a provider survey expressed a desire for availability of the following products to cover clinical needs: methylphenidate OROS, an IR methylphenidate product, mixed amphetamine salts ER, and atomoxetine.

12) The narcolepsy drug modafinil provides a unique niche in therapy as a wakefulness promoting agent.

13) The narcolepsy drug sodium oxybate has a high incidence of adverse events, but serves a unique niche in therapy for cataplexy. The manufacturer's restricted distribution program limits use to appropriate patients.

14) Based on clinical issues alone, there are no reasons to designate any of the ADHD drugs or narcolepsy drugs as non-formulary under the UF.

Relative Cost Effectiveness Conclusion: Based on the results of the cost analysis (CMA) and other clinical and cost considerations, the P&T Committee voted (15 for, 0 opposed, 0 abstained, 2 absent) that:

1) Once daily ADHD agents: dexmethylphenidate SODAS (Focalin XR) and methylphenidate transdermal system (Daytrana) were not cost-effective relative to the other agents in the subclass.

2) Multiple daily use ADHD agents: dexmethylphenidate IR (Focalin) was not cost-effective relative to the other agents in the subclass.

3) Agents indicated in the treatment of narcolepsy: Although modafinil (Provigil) and sodium oxybate (Xyrem) were more costly relative to other agents indicated for the

treatment of narcolepsy, they possessed unique clinical advantages relative to other agents within the class.

A. COMMITTEE ACTION: UF RECOMMENDATION **-** Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of the ADHD and narcolepsy agents, and other relevant factors, the P&T Committee, based upon its collective professional judgment, voted (15 for, 0 opposed, 0 abstained, 2 absent) to recommend that mixed amphetamine salts IR (Adderall, generics), mixed amphetamine salts ER (Adderall XR), atomoxetine (Strattera), dexamphetamine IR (Dexedrine, Dextrostat, generics), methamphetamine IR (Desoxyn, generics), methylphenidate 30% IR/70% ER (Metadate CD), methylphenidate IR (Ritalin, generics), methylphenidate OROS (Concerta), methylphenidate SODAS (Ritalin LA), methylphenidate sustained-release (SR) (Ritalin SR), modafinil (Provigil), and sodium oxybate (Xyrem) be maintained as formulary on the UF and that dexmethylphenidate IR (Focalin), dexmethylphenidate SODAS (Focalin XR), and methylphenidate transdermal system (Daytrana) be classified as non-formulary under the UF. (See paragraphs 7A, 7B and 7C on pages 25-39 of the P&T Committee minutes).

Approved, but modified as follows:

B. COMMITTEE ACTION: MEDICAL NECESSITY CRITERIA **-** Based on the clinical evaluation for methylphenidate transdermal system (Daytrana), dexmethylphenidate IR (Focalin), and dexmethylphenidate SODAS (Focalin XR), and the conditions for establishing medical necessity for a non-formulary medication provided for in the UF rule, the P&T Committee recommended (15 for, 0 opposed, 0 abstained, 2 absent) medical necessity criteria for methylphenidate transdermal system (Daytrana), dexmethylphenidate IR (Focalin) and dexmethylphenidate SODAS (Focalin XR). (See paragraph 7D on page 39-40 of the P&T Committee minutes).

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

C. COMMITTEE ACTION: IMPLEMENTATION PERIOD **-** The P&T Committee voted (15 for, 0 opposed, 0 abstained, 2 absent) to recommend an effective date of the first Wednesday following a 90-day implementation period. The implementation period will begin immediately following approval by the Director, TMA. (See paragraph 7E on page 40 of the P&T Committee minutes).

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

D. COMMITTEE ACTION: BCF RECOMMENDATION - The P&T Committee voted (15 for, 0 opposed, 0 abstained, 2 absent) to recommend retaining mixed amphetamine salts ER (Adderall XR), methylphenidate OROS (Concerta), and methylphenidate IR (Ritalin, generics) as the BCF selections in this class. (See paragraph 7F on page 40 of the P&T Committee minutes).

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

8. PRIOR AUTHORIZATION REQUIREMENT (PA) FOR MODAFINIL (PROVIGIL)

The P&T Committee agreed that a PA was needed for modafinil, due to the potential for inappropriate use.

COMMITTEE ACTION – Based on its increasing use for off-label indications not well established by the medical literature, the P&T Committee recommended that a PA be required for modafinil (15 for, 0 against, 0 abstained, 2 absent). The Committee recommended that the PA should have an effective date of the first Wednesday following a 90-day implementation period, consistent with the recommended implementation period for non-formulary medications in the ADHD and narcolepsy agents class. The implementation period will begin immediately following approval by the Director, TMA. The Committee voted (15 for, 0 against, 0 abstained, 2 absent) to recommend PA criteria. (See paragraph 8 on pages 40-42 of the P&T Committee minutes.)

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

9. PA REQUIREMENT FOR FENTANYL PATCHES (DURAGESIC, GENERICS)

COMMITTEE ACTION – Based on safety concerns, the P&T Committee recommended that a PA be required for fentanyl patches (15 for, 0 against, 0 abstained, 2 absent). The criteria recommended by the P&T Committee are based on safety requirements in labeling and incorporate modifications to the Pharmacy Data Transaction Service (PDTS) that will allow automation of some PA criteria, reducing paperwork burden and cost. These modifications are scheduled for completion by December 2006. (See pages 41-43 of the P&T Committee minutes for rationale and summary of PA criteria.) The P&T Committee recommended that the PA should have an effective date no sooner than the first Wednesday following a 30-day implementation period, but as soon thereafter as possible based on availability of the automated PA capability in PDTS. (See paragraph 9 on pages 42-43 of the P&T Committee minutes.)

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

William Winkenwerder, Jr., M.D.
Date: 17 January 2007

Department of Defense
Pharmacy and Therapeutics Committee Minutes
15 November 2006

1. CONVENING

The Department of Defense (DoD) Pharmacy and Therapeutics (P&T) Committee convened at 0800 hours on 14 November 2006 at the DoD Pharmacoeconomic Center (PEC), Fort Sam Houston, Texas.

2. ATTENDANCE

A. Voting Members Present

CAPT Patricia Buss, MC, USN	DoD P&T Committee Chair
CAPT Mark Richerson, MSC, USN	DoD P&T Committee Recorder
MAJ Travis Watson, MSC, USA *for* CAPT William Blanche, MSC, USN	DoD Pharmacy Programs, TMA
No replacement *for* LtCol Roger Piepenbrink, MC	Air Force, Internal Medicine Physician
Maj Michael Proffitt, MC	Air Force, OB/GYN Physician
LtCol Brian Crownover, MC	Air Force, Physician at Large
LtCol Charlene Reith *for* LtCol Everett McAllister, BSC	Air Force, Pharmacy Officer
CDR Walter Downs, MC *for* LCDR Michelle Perrello, MC	Navy, Internal Medicine Physician
LCDR Scott Akins, MC	Navy, Pediatric Physician
CDR David Tanen, MC	Navy, Physician at Large
LT Tim Thompson *for* CAPT David Price, MSC	Navy, Pharmacy Officer
COL Doreen Lounsbery, MC	Army, Internal Medicine Physician
MAJ Roger Brockbank, MC	Army, Family Practice Physician
COL Ted Cieslak, MC	Army, Physician at Large
LTC Peter Bulatao, MSC for COL Isiah Harper, MSC	Army, Pharmacy Officer
CAPT Vernon Lew, USPHS	Coast Guard, Pharmacy Officer
Mr. Joe Canzolino	Department of Veterans Affairs

B. Voting Members Absent

COL Isiah Harper, MSC	Army, Pharmacy Officer
LtCol Roger Piepenbrink, MC	Air Force, Internal Medicine Physician
CAPT William Blanche, MSC, USN	DoD Pharmacy Programs, TMA
LtCol Everett McAllister, BSC	Air Force, Pharmacy Officer (Pharmacy Consultant)
CAPT David Price, MSC	Navy, Pharmacy Officer (Pharmacy Consultant)

C. Non-Voting Members Present

Mr. Lynn T. Burleson	Assistant General Counsel, TMA
LT Thomas Jenkins, MSC, USN	TMOP/TRRx COR

D. Non-Voting Members Absent

COL Kent Maneval, MSC, USA	Defense Medical Standardization Board
Ms Martha Taft	Health Plan Operations, TMA
Major Peter Trang, BSC, USAF	Defense Supply Center Philadelphia

E. Others Present

Lt Col James McCrary, MC, USAF	DoD Pharmacoeconomic Center
Maj Wade Tiller, BSC, USAF	DoD Pharmacoeconomic Center
Maj Josh Devine, BSC, USAF	DoD Pharmacoeconomic Center
LCDR Joe Lawrence, MSC, USN	DoD Pharmacoeconomic Center
CPT Josh Napier, MC, USA	DoD Pharmacoeconomic Center
SFC Daniel Dulak, USA	DoD Pharmacoeconomic Center
Mr. Dan Remund	DoD Pharmacoeconomic Center
Ms. Shana Trice	DoD Pharmacoeconomic Center
Mr. David Bretzke	DoD Pharmacoeconomic Center
Ms. Angela Allerman	DoD Pharmacoeconomic Center
Mr. Eugene Moore	DoD Pharmacoeconomic Center
Ms. Julie Liss	DoD Pharmacoeconomic Center
Ms. Elizabeth Hearin	DoD Pharmacoeconomic Center
Mr. Dave Flowers	DoD Pharmacoeconomic Center
Mr. David Meade	DoD Pharmacoeconomic Center
Ms. Harsha Mistry	DoD Pharmacoeconomic Center
Col Nancy Misel	IMA DoD PEC
Janet Dailey	VAPBM
Charles R. Brown	TMA/CMB

3. REVIEW MINUTES OF LAST MEETING

A. Corrections to the Minutes – August 2006 DoD P&T Committee meeting minutes were approved as written, with no corrections noted, however, there was a correction to the decision paper. The sentence on page 3, section B (Committee Action: Basic Core Formulary (BCF) Recommendation), line 3 was revised to "The Committee did not recommend addition of rosiglitazone/glimepiride to the BCF."

B. Approval of August Minutes - Dr. William Winkenwerder, Jr., M.D., approved the minutes of the August 2006 DoD P&T Committee meeting on 23 October 2006.

4. ITEMS FOR INFORMATION

TRICARE Management Activity (TMA) and DoD PEC staff members briefed the P&T Committee on the following:

A. Beneficiary Advisory Panel (BAP) Briefing – CAPT Buss and CAPT Richerson briefed the members of the P&T Committee regarding the August 2006 BAP meeting. The Committee was briefed on BAP comments regarding the DoD P&T Committee's Uniform Formulary (UF) and implementation recommendations.

B. Implementation Status of UF Decisions – The PEC briefed the members of the P&T Committee on the progress of implementation for drug classes reviewed for UF status since August 2005. The Committee made the following observations:

1) **DuetAct (pioglitazone plus glimepiride) –** A new thiazolidinedione (TZD) combination agent has been marketed since the TZD class was reviewed in August 06. DuetAct is the combination of pioglitazone plus glimepiride. It is available in two strengths: 30mg pioglitazone/2mg glimepiride and 30mg pioglitazone/4mg glimepiride. The PEC informed the Committee that DuetAct was added to the UF as a line extension of the existing UF blanket purchase agreements (BPAs) and voluntary agreements for TRICARE retail pharmacy rebates (VARR) with the manufacturer.

2) **Implementation Status of UF Decisions –** The PEC briefed the members of the Committee on the progress of implementation for drug classes reviewed for UF status since February 2005. The Committee made the following observations:

a) Utilization in all UF classes continues to remain stable, suggesting continued access to drugs within the reviewed classes.

b) Collective utilization of UF agents across all reviewed drug classes and points of service (military treatment facility (MTF), TRICARE Mail Order Pharmacy Program (TMOP), and TRICARE Retail Network Pharmacy (TRRx)) continues to increase as a percentage of prescriptions dispensed, while utilization of non-formulary agents has decreased. Based on the UF decisions that have been fully implemented since the first UF DoD P&T meeting in February 2005, there has been an overall 30% reduction in the use of non-formulary agents (MTFs -89%, Mail +6%, Retail -11%), including those classes where implementation has only just begun. In classes with at least 6 months of implementation, there has been an overall 40% reduction in the use of non-formulary agents (MTFs -93%, Mail +1%, Retail -21%).

c) The cost per day of treatment across all reviewed drug classes has decreased, but magnitude varies by point of service. Based on the UF decisions that have been fully implemented since the first UF DoD P&T meeting in February 2005, there has been an overall 5% reduction in the cost per day of treatment (MTFs -23%, Mail -5%, Retail -2%), including those classes where implementation has only just begun. In classes with at least 6 months of implementation, there has been an overall 7% reduction in the cost per day of treatment (MTFs -30%, Mail -5%, Retail -4%).

d) Success in terms of generating increased market share for UF agents (while decreasing market share for non-formulary agents) varies by class and point of service.

e) Market shares by point of service continue to reflect the degree of utilization management applied to each point of service. The more highly managed points of service (i.e., MTFs) are generating higher market shares for UF agents than the unmanaged points of service (i.e., TMOP and TRRx).

f) It appears that more beneficiaries may be electing to receive non-formulary medications through TMOP.

5. REVIEW OF RECENTLY APPROVED AGENTS

A. Recently Approved Agents in Classes Not Yet Reviewed for the UF

The P&T Committee was briefed on four new drugs that were approved by the Food and Drug Administration (FDA) (see Appendix B). The P&T Committee determined that these four new drugs fall into drug classes that have not yet been reviewed for UF status; therefore, UF consideration was deferred until drug class reviews are completed.

The P&T Committee discussed the need for quantity limits or prior authorization (PA) requirements for two of these products: inhaled insulin (Exubera) and fentanyl buccal tablets (Fentora). Quantity limits are in place for other inhaled products (e.g., for asthma) and for fentanyl transmucosal lozenges or "lollipops" (Actiq). Some other health plans require PA for human insulin inhalation powder. The Committee agreed that more information was needed before making recommendations; the Narcotic Analgesic drug class is scheduled for UF review in February 2007.

B. Contraceptive Agents - 30/10 mcg ethinyl estradiol (EE)/0.15 mg levonorgestrel for extended use, (Seasonique), and 20 mcg ethinyl estradiol (EE)/1 mg norethindrone – 24 day regimen, (Loestrin 24 Fe)

1) *Relative Clinical Effectiveness* – Two new contraceptive products, Seasonique and Loestrin 24 Fe, have been marketed since the contraceptive drug class was reviewed in May 06.

Seasonique – Seasonique is a monophasic oral contraceptive with 30 mcg of EE specifically packaged and labeled for extended cycle use (84 days of 30 mcg EE/0.15 mg levonorgestrel, followed by seven days of low-dose estrogen [10 mcg EE]).

The UF contains multiple monophasic oral contraceptives containing 30 mcg of EE in combination with various progestogens. These products include Yasmin (3 mg

drospirenone) and generic equivalents to Desogen (0.15 mg desogestrel); Loestrin 1.5/30, Loestrin Fe 1.5/30 (1.5 mg norethindrone); Lo/Ovral (0.3 mg norgestrel); and Nordette (0.15 mg levonorgestrel). Two of these (Nordette equivalent products and Yasmin) are on the BCF. All of these products are available in conventional 28-day packaging (21 days of active tablets followed by 7 days of placebo tablets).

Another extended cycle product, Seasonale, was placed in the third (non-formulary) tier of the UF following the May 06 meeting, with an effective date of 24 Jan 2007. The difference between Seasonale and Seasonique is the substitution of the seven low-dose estrogen (10 mcg EE) tablets in Seasonique for the seven placebo tablets in Seasonale. For this reason, Seasonique's regimen cannot be exactly duplicated by using conventional packages of Nordette or its equivalents and discarding unneeded placebo tablets, unlike Seasonale.

The rationale for providing seven days of 10 mcg EE instead of placebo is to reduce symptoms associated with estrogen withdrawal, including dysmenorrhea, menstrual migraine, and premenstrual syndrome, although this has not been evaluated in a prospective, randomized, controlled trial. One other oral contraceptive product offering low-dose estrogen during the off period is available (Mircette, Kariva, and equivalents; 21 days of 20 mcg EE/0.15 mg desogestrel followed by 2 days of placebo and 5 days of 10 mcg EE). It is worth noting that utilization of this product, which is included on the UF, is relatively low compared to other 20 mcg EE products. Alternatives to Seasonique in women being treated on an extended cycle basis who are experiencing menstrual-related problems during the four annual off periods include addition of a low-dose conjugated estrogen product (e.g., 0.3 mg Premarin) during the off period, or decreasing the length or number of off periods.

With respect to efficacy in preventing pregnancy, there is no reason to believe that Seasonique would differ from other similar oral contraceptives. One non-controlled trial evaluating Seasonique in 1,000 women reported that it was >99% effective in preventing pregnancy; there are no head-to-head trials comparing Seasonique with other contraceptives.

Loestrin 24 Fe – Loestrin 24 Fe is a monophasic oral contraceptive product with 20 mcg EE packaged as a 24-day regimen (24 days of 20 mcg EE / 1 mg norethindrone followed by four days of placebo tablets).

The UF contains multiple monophasic oral contraceptives containing 20 mcg of EE in combination with various progestogens, including Yaz (3 mg drospirenone) and equivalents to Alesse (0.1 mg levonorgestrel) and Loestrin 1/20 / Loestrin Fe 1/20 (1.0 mg norethindrone). Alesse equivalent products and Yaz are on the BCF. Like Loestrin 24 Fe, Yaz is a 24-day regimen product; Alesse, Loestrin 1/20, and Loestrin Fe 1/20 are available in conventional 28-day packaging (21 days of active tablets followed by 7 days of placebo tablets). Loestrin 24 Fe offers the same daily estrogen and progestogen content as the existing Loestrin Fe 1/20 product (and its generic equivalents), differing only in the number of active and placebo tablets included.

The rationale for a 24- rather than a 21-day regimen is to decrease the number of bleeding days and reduce adverse events associated with estrogen withdrawal. It is also possible that a longer regimen would increase the safety margin for contraceptive

effectiveness with low estrogen products; however, there is no supporting clinical evidence. One trial in 938 women compared Loestrin 24 Fe with Loestrin Fe 1/20 and reported a Pearl Index (number of pregnancies per 100 women per year of use) of 1.85 (five pregnancies) with the 24-day regimen vs. 1.79 (two pregnancies) with the 21-day regimen (no statistics provided). There were no differences between the two products in terms of serious adverse events, treatment-related adverse events, and discontinuations due to adverse events.

An alternative using conventionally packaged Loestrin Fe 1/20 that may accomplish the same general goals as with the 24-day regimen would be to simply start a new package early.

Conclusion: The Committee concluded that Seasonique or Loestrin 24 Fe do not have a significant, clinically meaningful therapeutic advantage in terms of safety, effectiveness, or clinical outcome, over other oral contraceptives included on the UF.

2) *Relative Cost Effectiveness* – The P&T Committee evaluated the relative cost-effectiveness of Seasonique and Loestrin 24 Fe in relation to efficacy, safety, tolerability, and clinical outcomes of the other agents in the contraceptive drug class. Information considered by the P&T Committee included, but was not limited to, sources of information listed in 32 CFR 199.21(e)(2).

   Based on the information reported from the relative clinical effectiveness evaluation, there was insufficient evidence to suggest that Seasonique or Loestrin 24 Fe differed with regard to efficacy, safety, tolerability, or clinical outcomes compared to the existing drugs in the contraceptive class. As a result, two cost-minimization analyses (CMAs) were performed to determine the relative cost-effectiveness of Seasonique and Loestrin 24 Fe.

   The CMA for Seasonique compared the weighted average cost per cycle across all three points of service to the monophasic oral contraceptives with 30 mcg of EE, as listed above. The CMA for Loestrin 24 Fe compared the weighted average cost per cycle across all three points of service to the monophasic oral contraceptives with 20 mcg of EE, as listed above.

   Conclusion for Seasonique: The results of the CMA showed that Seasonique is less cost-effective on a per cycle basis than all UF oral contraceptives containing 30 mcg EE.

   Conclusion for Loestrin 24 Fe: The results of the CMA showed that Loestrin 24 Fe is less cost-effective on a per cycle basis than all UF oral contraceptives containing 20 mcg EE.

3) *UF Recommendations* – The P&T Committee voted (15 for, 0 opposed, 0 abstained, 2 absent) to accept the clinical and cost effectiveness conclusions stated above.

   COMMITTEE ACTION – Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations, and other relevant factors, the P&T Committee, based upon its collective professional judgment, voted (15 for, 0 opposed, 0 abstained, 2 absent) to recommend that Seasonique and Loestrin 24 Fe be classified as non-formulary under the UF.

4) *Medical Necessity Criteria* – Based on the clinical evaluation of Seasonique, and the conditions for establishing medical necessity for a non-formulary medication provided for in the UF rule, the P&T Committee recommended the following general medical necessity criteria for Seasonique:

   a) Use of formulary alternatives is contraindicated.

   b) The patient has experienced or is likely to experience significant adverse effects from formulary alternatives.

   c) Use of formulary alternatives has resulted in therapeutic failure.

   Based on the clinical evaluation of Loestrin 24 Fe, and the conditions for establishing medical necessity for a non-formulary medication provided for in the UF rule, the P&T Committee recommended the following general medical necessity criteria for Loestrin 24 Fe:

   a) Use of formulary alternatives is contraindicated.

   The P&T Committee did not agree that other general medical necessity criteria would apply to Loestrin 24 Fe given the UF status of Loestrin Fe 1/20, which contains the same combination of the same active ingredients and which can be used on the same shortened off-period basis by discarding unneeded placebo tablets.

   COMMITTEE ACTION: The P&T Committee voted (15 for, 0 opposed, 0 abstained, 2 absent) to approve the medical necessity criteria outlined above.

5) *UF Implementation Period* – The P&T Committee discussed the advantages and disadvantages of a longer versus a shorter implementation period for Seasonique and Loestrin 24 Fe. The fact that Seasonique is packaged as a three-month supply supported a longer implementation period, while a shorter implementation period would avoid patient disruption as utilization of new products increases. As of Oct 2006, there have been 161 unique utilizers of Seasonique and 2,227 of Loestrin 24 Fe, at all three points of service. The P&T Committee also discussed the prospect for coordinating implementation of non-formulary status for Seasonique and Loestrin 24 Fe with the already established effective date for Seasonale non-formulary status (24 Jan 07), but it was unclear if this was possible given timelines for the BAP meeting and subsequent review of P&T minutes and BAP comments by the Director, TMA. Ultimately, the Committee recommended a shorter implementation period because it would avoid patient disruption as utilization of new products increases.

   COMMITTEE ACTION: The P&T Committee recommended (15 for, 0 opposed, 0 abstained, 2 absent) an effective date of the first Wednesday following a 60-day implementation period. The implementation period will begin immediately following approval by the Director, TMA.

C. Topical Antifungal Agents - 0.25% miconazole, 15% zinc oxide, 81.35% white petrolatum ointment (Vusion)

1) *Relative Clinical Effectiveness:* The topical antifungal agents were reviewed by the P&T Committee in Aug 05. Topical antifungal agents included on the UF include clotrimazole (Lotrimin, generics), nystatin (Mycostatin, generics), miconazole (Monistat, generics), ketoconazole (Nizoral, generics), butenafine (Mentax, generics),

and naftifine (Naftin). Clotrimazole (Lotrimin, generics) and nystatin (Mycostatin, generics) are classified as BCF agents. Topical antifungal agents classified as non-formulary under the UF are econazole (Spectazole, generics), sertaconazole (Ertaczo), sulconazole (Exelderm), ciclopirox (Loprox, generics), and oxiconazole (Oxistat).

Vusion contains 0.25% miconazole along with 15% zinc oxide and 81.35% white petrolatum, and is only available as an ointment. Over-the-counter (OTC) and prescription miconazole products contain a 2% concentration of miconazole, and are available in several formulations (e.g., cream, ointment, spray, spray liquid, powder, and solution). The zinc oxide and petrolatum components of Vusion are skin protectants; numerous OTC products (e.g., Balmex, Happy Hiney) contain varying amounts of these two ingredients, which form a physical barrier on the skin.

Vusion is specifically labeled for the adjunctive treatment of diaper dermatitis only when complicated by microscopically-documented candidiasis in immunocompetent pediatric patients four weeks and older. Vusion is the first product with a labeled indication for diaper rash in infants as young as four weeks, and the first one to include candidiasis in the label. Vusion is not approved for use in adults, immunocompromised patients, or infants with diaper rash that is not confirmed to have candidiasis as the causative factor. The Committee agreed that Vusion is likely to be used for non FDA-approved indications, particularly for diaper rash without documented candidiasis. The existing BCF and UF topical antifungal products have much broader indications than Vusion and treat several types of infections (e.g., tinea pedis, tinea corporis, tinea cruris, or tinea capitis).

The rationale for Vusion incorporating a low concentration of 0.25% miconazole is to provide efficacy and safety in young infants without achieving measurable plasma concentrations. It is not clear, however, that Vusion is the only topical antifungal that may be used for this purpose. Nystatin (Mycostatin, generics) can be used in infants as young as neonates, and the package insert states that it is well tolerated, even in debilitated infants, even with prolonged administration. Both miconazole (Monistat, generics) 2% and clotrimazole (Lotrimin, generics) 1% can be used in children as young as two years of age.

There are no published clinical trials comparing Vusion with other miconazole formulations, clotrimazole (Lotrimin, generics) or nystatin (Mycostatin, generics). One published, 330-patient trial compared Vusion with a zinc oxide/petrolatum vehicle and reported a complete cure rate after seven days of 7% with Vusion versus 0.8% with vehicle; adverse event rates with Vusion were similar to vehicle.

Conclusion: The P&T Committee concluded that, although Vusion is labeled for a specific type of diaper dermatitis in infants as young as four weeks of age, it does not have a significant, clinically meaningful therapeutic advantage in terms of safety, effectiveness, or clinical outcome over other topical antifungals included on the UF.

2) *Relative Cost Effectiveness:* The P&T Committee evaluated the relative cost-effectiveness of Vusion in relation to efficacy, safety, tolerability, and clinical outcomes of the other agents in the topical antifungal drug class. Information considered by the P&T Committee included, but was not limited to, sources of information listed in 32 CFR 199.21(e)(2).

Based on the information reported from the relative clinical effectiveness evaluation, there was insufficient evidence to suggest that Vusion differed significantly with regard to efficacy, safety, tolerability, or clinical outcomes compared to the existing drugs in the topical antifungal class. As a result, a CMA was performed to determine the relative cost-effectiveness of Vusion within the topical antifungal drug class.

The CMA for Vusion compared the weighted cost per treated utilizer across all three points of service to other antifungal agents previously analyzed during the DoD P&T Committee's August 2005 review of topical antifungals. Comparative antifungals used specifically for diaper rash included clotrimazole (Lotrimin, generics), miconazole (Monistat, generics), and nystatin (Mycostatin, generics). Other topical antifungals compared included cyclopirox (Loprox, generics), sertaconazole (Ertaczo), oxiconazole (Oxistat), naftifine (Naftin), butenafine (Mentax), sulconazole (Exelderm), econazole (Spectazole, generics), and ketoconazole (Nizoral, generics).

Conclusion: The results of the CMA showed that Vusion is the least cost-effective of all comparators, when analyzed on a cost per utilizer basis.

3) *UF Recommendation:* The P&T Committee voted (15 for, 0 opposed, 0 abstained, 2 absent) to accept the clinical and cost effectiveness conclusions stated above.

   COMMITTEE ACTION – Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations, and other relevant factors, the P&T Committee, based upon its collective professional judgment, voted (15 for, 0 opposed, 0 abstained, 2 absent) to recommend that Vusion be classified as non-formulary under the UF.

4) *Medical Necessity Criteria:* Based on the clinical evaluation of Vusion, and the conditions for establishing medical necessity for a non-formulary medication provided for in the UF rule, the P&T Committee recommended the following general medical necessity criteria for Vusion:

   a) Use of formulary agents is contraindicated.

   b) The patient has experienced or is likely to experience significant adverse effects from formulary alternatives.

   COMMITTEE ACTION: The P&T Committee voted (15 for, 0 opposed, 0 abstained, 2 absent) to approve the medical necessity criteria outlined above.

5) *UF Implementation Period:* The P&T Committee recommended an implementation period of 60 days, due to existing low utilization in the MHS. As of October 2006, a total of 581 Vusion prescriptions have been dispensed at all three points of service. For the six month period between Apr 2006 and Oct 2006, there have been 426 unique utilizers of Vusion in the MHS.

   COMMITTEE ACTION: The P&T Committee recommended (15 for, 0 opposed, 0 abstained, 2 absent) an effective date of the first Wednesday following a 60-day implementation period. The implementation period will begin immediately following approval by the Director, TMA.

D. Antiemetic Agents (Cesamet)

1) *Relative Clinical Effectiveness:* The Committee previously reviewed the antiemetic agents at the May 06 P&T meeting. The antiemetic class includes the following agents, which may be sub-classified based on typical use and mechanism of action. All of these agents are on the UF with the exception of dolasetron (Anzemet).

   - *The newer antiemetics*
     - 5-hydroxytryptamine-3 [5-HT3] antagonists: ondansetron (Zofran), granisetron (Kytril), dolasetron (Anzemet)
     - Neurokinin-1 (NK-1) antagonist: aprepitant (Emend)
   - *The older antiemetics*
     - Cannabinoids: dronabinol (Marinol)
     - Antihistamines: meclizine (Antivert, generics) and promethazine (Phenergan, generics). Promethazine is on the BCF.
     - Phenothiazines: prochlorperazine (Compazine, generics), thiethylperazine (Torecan)
     - Anticholinergics: trimethobenzamide (Tigan, generics), transdermal scopolamine (Transderm Scop)

   Nabilone (Cesamet) is a synthetic cannabinoid antiemetic similar to dronabinol. It was previously approved for marketing in 1985, but withdrawn by the manufacturer in 1989 due to commercial reasons not related to efficacy or safety. It is indicated for treatment of chemotherapy-induced nausea and vomiting (CINV) when conventional antiemetics have failed. The other available cannabinoid antiemetic, dronabinol, is also indicated for CINV, but has an additional indication for treating anorexia in patients with AIDS. The duration of action of nabilone is longer than dronabinol: 8-12 hours vs. 4-6 hours. This allows for a dosing regimen of BID-TID (2 to 3 times a day) with nabilone, compared to TID-QID (3 to 4 times a day) for dronabinol.

   There are no published clinical trials comparing nabilone with dronabinol (Marinol). Additionally, there are no trials comparing nabilone with any of the 5-HT3 antagonists—ondansetron, granisetron, or dolasetron – which have replaced older antiemetics as the standard of care for CINV. Nabilone was approved by the FDA based on clinical trial data submitted in the early 1980s. In published trials, nabilone showed superior efficacy to prochlorperazine, but with an increased incidence of adverse effects; another trial found the combination of nabilone plus prochlorperazine inferior to a combination of dexamethasone plus metoclopramide.

   The psychoactive adverse effects of nabilone relegate it to use as a second-line agent. Nabilone is a DEA (Drug Enforcement Administration) Schedule II drug, compared to dronabinol, a Schedule III drug.

   Conclusion: The P&T Committee concluded that, while nabilone offers a slight convenience of dosing frequency compared to the other cannabinoid antiemetics, dronabinol, it does not have a significant, clinically meaningful therapeutic advantage in terms of safety, effectiveness, or clinical outcomes over other antiemetics included on the UF.

2) *Relative Cost Effectiveness:* The P&T Committee evaluated the relative cost-effectiveness of nabilone in relation to efficacy, safety, tolerability, and clinical outcomes of the other agents in the antiemetic class. Information considered by the P&T Committee included, but was not limited to, sources of information listed in 32 CFR 199.21(e)(2).

   Based on the information reported from the relative clinical effectiveness evaluation, there was insufficient evidence to suggest that nabilone differed with regards to efficacy, safety, tolerability, or clinical outcomes compared to the other antiemetics. As a result, a CMA was performed to determine the relative cost-effectiveness of the nabilone within the antiemetic drug class.

   The CMA compared the ranges of cost per day of treatment at all three points of service (at recommended starting doses) for nabilone versus the other cannabinoid antiemetic dronabinol, which is currently included on the UF.

   Conclusion: The results of the CMA showed that nabilone has a cost-effectiveness profile that is similar to dronabinol.

3) *UF Recommendations:* The P&T Committee voted (15 for, 0 opposed, 0 abstained, 2 absent) to accept the clinical and cost effectiveness conclusions stated above.

   COMMITTEE ACTION – Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations, and other relevant factors, the P&T Committee, based upon its collective professional judgment, voted (15 for, 0 opposed, 0 abstained, 2 absent) to recommend that nabilone be maintained as formulary on the UF.

4) *Medical Necessity Criteria:* Since nabilone was not recommended for non-formulary status under the UF, establishment of medical necessity criteria is not applicable.

5) *UF Implementation Period:* Since nabilone was not recommended for non-formulary status under the UF, establishment of an implementation plan is not applicable.

6. DRUG CLASS REVIEW – OLDER SEDATIVE HYPNOTICS (SED-2s)

The P&T Committee evaluated the relative clinical effectiveness of the Older Sedative/Hypnotic Medications (SED-2s). The SED-2 drug class is comprised of five hypnotic benzodiazepines: estazolam (Prosom, generics), flurazepam (Dalmane, generics), quazepam (Doral), temazepam (Restoril, generics), and triazolam (Halcion, generics); two barbiturate hypnotics: butabarbital (Butisol) and secobarbital (Seconal, generics); and one nonbarbiturate hypnotic agent: chloral hydrate (generics). All eight of these drugs have been marketed for a number of years, and all but quazepam (Doral), and the 7.5 mg and 22.5 mg strengths of temazepam (Restoril) are available in generic formulations. The SED-2 drug class accounted for $2.5 million in MHS expenditures for the period August 2005 to July 2006 and is ranked #165 in terms of total expenditures during that time period. In terms of numbers of prescriptions dispensed for all sedative hypnotics in the MHS, the SED-2 agents account for 20% of the overall market, with the newer non-benzodiazepine sedative

hypnotics – eszopiclone (Lunesta), zolpidem (Ambien), ramelteon (Rozerem) and zaleplon (Sonata) – accounting for the remaining 80%.

A. SED-2s – Relative Clinical Effectiveness

The P&T Committee evaluated the relative clinical effectiveness of the SED-2s currently marketed in the United States. Information regarding the safety, effectiveness, and clinical outcomes of these drugs was considered. The clinical review included, but was not limited to, the requirements stated in the UF Rule, 32 CFR 199.21(e)(1). The P&T Committee was advised that there is a statutory presumption that pharmaceutical agents in a therapeutic class are clinically effective and should be included on the UF, unless the P&T Committee finds by a majority vote that a pharmaceutical agent does not have a significant, clinically meaningful therapeutic advantage in terms of safety, effectiveness, or clinical outcome over the other pharmaceutical agents included on the UF in that therapeutic class.

1) Efficacy

Hypnotic benzodiazepines – The hypnotic benzodiazepines [estazolam (Prosom, generics), flurazepam (Dalmane, generics), quazepam (Doral), temazepam (Restoril, generics), and triazolam (Halcion, generics)] are indicated for the short-term (two weeks or less) treatment of insomnia. When given before bedtime, all five hypnotic benzodiazepines have been shown in numerous clinical trials to improve total sleep time, sleep latency, and number of awakenings, and they are effective in reducing early morning awakening. When used in equipotent doses, all the hypnotic benzodiazepines are effective and considered therapeutically interchangeable for short-term treatment of insomnia. Like other benzodiazepines, the hypnotic benzodiazepines are also effective in treating anxiety disorders.

Temazepam (Restoril, generics) is frequently preferred over flurazepam (Dalmane, generics), as the latter has a long half-life (47-160 hours compared to 3.5-18.4 hours for temazepam) that increases the occurrence of residual sedative effects. Triazolam (Halcion, generics) is commonly considered by providers to have an unacceptable adverse effect profile. Quazepam (Doral) and estazolam (Prosom, generics) are infrequently used; they were late entrants to the market, have longer half-lives, and offer no real clinical advantage compared to temazepam.

The agents are selected for clinical use according to their pharmacokinetic profiles (onset of action, duration of action), which vary among the agents. Although much of their usage has been supplanted by the newer sedative hypnotic drug class, the hypnotic benzodiazepines are still utilized for the short-term treatment of insomnia.

Hypnotic barbiturates – The hypnotic barbiturates include butabarbital (Butisol), and secobarbital (Seconal, generics). Secobarbital has been used in the short-term treatment of insomnia, and also in the pre-operative setting and in alcohol withdrawal. Butabarbital (Butisol) has a half-life of 34 to 42 hours, and is also effective as a sedative.

The hypnotic barbiturates have no safety or efficacy advantage compared to the benzodiazepines or newer sedative hypnotics, and their use has largely fallen out of favor for the treatment of insomnia. They may have a niche in therapy when the

benzodiazepines or newer hypnotics are contraindicated in an individual patient, or in the setting of pre-operative sedation.

Chloral hydrate - Chloral hydrate is no longer routinely used as a primary treatment for insomnia, as it is not as effective as the benzodiazepines. Chloral hydrate is more commonly used preoperatively or prior to procedures to ally anxiety or induce sedation. It has a unique niche for use in the setting of outpatient pediatric sedation, due to the perception that chloral hydrate produces less paradoxical excitement than the barbiturates. Chloral hydrate is included in the 1992 update to the American Academy of Pediatric (AAP) guidelines for pediatric sedation.

2) Safety / Tolerability

Benzodiazepines – There are no major differences between the five hypnotic benzodiazepines with respect to safety and tolerability. Adverse events that include daytime sedation, memory problems, and falls may limit utility, especially in the elderly. There are also concerns that benzodiazepines may limit deep sleep. The class is deemed relatively safe based on more than 30 years of clinical use. The agents have differing safety profiles with respect to drug interactions, anterograde amnesia, and daytime sedation. All benzodiazepines are contraindicated in pregnancy.

Hypnotic barbiturates – The hypnotic barbiturates have multiple safety and abuse/addiction concerns and a self-limiting mechanism of action; overdoses can be lethal. They also induce the action of hepatic microsomal drug-metabolizing enzymes, leading to increased metabolism of many drugs and endogenous substrates, such as steroid hormones, cholesterol, bile salts, and several others. Secobarbital (Seconal, generics) and butabarbital (Butisol) have been associated with withdrawal symptoms, such as multiple seizures or psychosis similar to alcohol delirium; disorientation, hallucinations, and even death have been reported. They are classified as pregnancy category D. These products were largely replaced by the benzodiazepines.

Chloral hydrate – Chloral hydrate has been associated with cardiac dysrhythmias in both adults and children. Chloral hydrate has numerous safety concerns when it is administered to children for pre-operative sedation prior to the child's arrival at the clinic; however, when properly administered it is both safe and effective. The drug has not been studied in pregnancy; a limited number of reports indicate use with no fetal harm. The AAP recommends that, while chloral hydrate can be safely administered to lactating women, infants should be observed for symptoms of drowsiness as drug and metabolites are excreted into breast milk.

Clinical Effectiveness Conclusion – The older sedative hypnotic drugs still play a role in the treatment of insomnia and pre-operative sedation, although they have been largely replaced by newer agents in clinical practice. It is widely accepted that the five hypnotic benzodiazepines are therapeutically interchangeable, although temazepam (Restoril, generics) has the most favorable half-life and safety profile. The barbiturates and chloral hydrate are used infrequently and primarily for special patient populations. There are no clinical reasons to justify designating any of these eight drugs as non-formulary under the UF.

COMMITTEE ACTION – The P&T Committee voted (15 for, 0 opposed, 0 abstained, 2 absent) to accept the clinical effectiveness conclusions stated above.

B. SED-2s – Relative Cost Effectiveness

The P&T Committee evaluated the relative cost-effectiveness of the SED-2 (older sedative hypnotic) agents in relation to efficacy, safety, tolerability, and clinical outcomes of the other agents in the class. Information considered by the P&T Committee included, but was not limited to, sources of information listed in 32 CFR 199.21(e)(2).

A cost-minimization analysis was employed to assess the relative cost-effectiveness of the agents within the SED-2 therapeutic class. The agents were evaluated on their weighted average cost per day of therapy. The results of the analysis showed all of the agents to have similar relative cost-effectiveness, with the exception of the brand-only agents: quazepam (Doral), butabarbital (Butisol), and temazepam (Restoril) 7.5 and 22.5mg. Although these agents were less cost-effective relative to the other agents in the class, the Committee agreed that little savings would be achieved by placing any of these agents in the non-formulary tier due primarily to their low current and projected MHS utilization/expenditures. Butabarbital and quazepam account for less than 0.25% of SED-2 prescriptions across the MHS and approximately 2% of annual SED-2 MHS expenditures. Temazepam (Restoril) 7.5 and 22.5 mg account for less than 5% of all MHS prescriptions for temazepam.

Cost Effectiveness Conclusion – The P&T Committee concluded that:

3) Secobarbital (Seconal, generics), chloral hydrate (generics), temazepam (Restoril, generics) 15 and 30 mg, estazolam (Prosom, generics), and triazolam (Halcion, generics) have similar relative cost-effectiveness.

4) Butabarbital (Butisol), quazepam (Doral), and temazepam (Restoril) 7.5 and 22.5mg are more costly relative to the other agents in the class, but placing these agents in the non-formulary tier of the UF would achieve little savings due to current and projected low utilization.

COMMITTEE ACTION – The P&T Committee voted (15 for, 0 opposed, 0 abstained, 2 absent) to accept the cost effectiveness conclusions stated above.

C. SED-2s – UF Recommendations

COMMITTEE ACTION – Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of the SED-2 agents, and other relevant factors, the P&T Committee, based upon its collective professional judgment, voted (15 for, 0 opposed, 0 abstained, 2 absent) to recommend that butabarbital (Butisol), secobarbital (Seconal, generics), chloral hydrate (generics), quazepam (Doral), temazepam (Restoril), estazolam (Prosom, generics), and triazolam (Halcion, generics) be maintained as formulary on the UF and that no agents be classified as non-formulary under the UF.

D. SED-2s – Medical Necessity Criteria – Since no agents were recommended for non-formulary status under the UF, establishment of medical necessity criteria is not applicable.

E. SED-2s – UF Implementation Period – Since no agents were recommended for non-formulary status under the UF, establishment of an implementation plan is not applicable.

F. SED-2s – Basic Core Formulary (BCF) Review and Recommendations – The P&T Committee had previously determined that at least one SED-2 agent should be added to the BCF based on the clinical and cost effectiveness review. As a result of the clinical and economic evaluations presented, the P&T Committee recommended that temazepam (Restoril, generics) 15 and 30 mg be added to the BCF. These strengths of temazepam are generically available and represent more than 95% of temazepam prescriptions. Temazepam is the most commonly used, clinically preferred, and cost-effective SED-2 agent at all points of service.

COMMITTEE ACTION – The P&T Committee voted (15 for, 0 opposed, 0 abstained, 2 absent) to recommend adding temazepam 15 and 30 mg as the BCF selection in this class.

7. DRUG CLASS REVIEW – ATTENTION-DEFICIT / HYPERACTIVITY DISORDER AND NARCOLEPSY AGENTS

The drugs in the Attention-Deficit / Hyperactivity Disorder (ADHD) and Narcolepsy Agents class are comprised of the following: for ADHD, there is one non-stimulant: atomoxetine (Strattera) and five stimulant compounds: methylphenidate, mixed amphetamine salts, dexmethylphenidate, dextroamphetamine, and methamphetamine; for narcolepsy, there are two drugs: modafinil (Provigil) and sodium oxybate (Xyrem). The ADHD and Narcolepsy Agents accounted for approximately $84.5 million dollars in MHS expenditures for Fiscal Year (FY) 2006 and are ranked #16 in terms of total expenditures during that time period.

The ADHD stimulant drugs are further divided into once daily products and multiple daily use products, based on differences in drug delivery mechanism. There are four once daily methylphenidate formulations: 1) an osmotically controlled-release delivery system [OROS)] tablet (Concerta); 2) a 30% immediate release (IR) and 70% extended release (ER) beads in a capsule (Metadate CD); 3) a mixture of 50% IR and 50% ER beads in a capsule using a spheroidal oral drug absorption system [SODAS] (Ritalin LA); and 4) a transdermal system (Daytrana patch). The other stimulant once daily products include mixed amphetamine salts ER (Adderall XR) and dexmethylphenidate SODAS (Focalin XR).

Multiple daily use products include five methylphenidate products: Ritalin, Ritalin sustained release (SR) (generics), Metadate ER (generics), Methylin ER (generics), and Methylin (generics). Other multiple daily use products include mixed amphetamine salts IR (Adderall, generics), dexmethylphenidate IR (Focalin), dextroamphetamine IR (Dexedrine, Dextrostat, generics), and methamphetamine IR (Desoxyn, generics).

A. ADHD and Narcolepsy Agents – Relative Clinical Effectiveness

The P&T Committee evaluated the relative clinical effectiveness of the ADHD and narcolepsy agents currently marketed in the United States. Information regarding the safety, effectiveness, and clinical outcomes of these drugs was considered. The clinical review included, but was not limited to, the requirements stated in the UF Rule, 32 CFR 199.21(e)(1). The P&T Committee was advised that there is a statutory presumption that pharmaceutical agents in a therapeutic class are clinically effective and should be included on the UF, unless the P&T Committee finds by a majority vote that a

pharmaceutical agent does not have a significant, clinically meaningful therapeutic advantage in terms of safety, effectiveness, or clinical outcome over the other pharmaceutical agents included on the UF in that therapeutic class.

1) Efficacy

a) ADHD Drugs

i) Standard Therapy – Stimulants have remained the mainstay of therapy for treating children with ADHD. A systematic review completed by the state of Oregon Health and Science University Drug Effectiveness Review Program (DERP) concluded that the overall response rate with the stimulants ranges from 60-80%, but varying definitions of response were reported in the clinical trials.

ii) Clinical Trials – Interpretation of the efficacy literature is difficult due to the poor study design of published trials, use of different outcome rating scales, the limited number of comparator trials available, small number of patients enrolled in the studies, and overall short duration of evaluation. Direct comparisons of the trials are difficult, due to wide heterogeneity among trials and use of different ADHD rating scales.

IR versus IR stimulant products – The DERP systematic review compared the clinical efficacy of dextroamphetamine IR (Dexedrine, Dextrostat, generics) to methylphenidate IR (Ritalin, generics); reviewers concluded that none of the studies showed an efficacy difference between the two IR stimulants.

Two studies [Pelham 1999, Pliska 2000] that compared methylphenidate IR (Ritalin, generics) vs. mixed amphetamine salts IR (Adderall, generics) did not show a difference in efficacy. A study [Wigal 2004] comparing dexmethylphenidate IR (Focalin) with Adderall also found no difference in efficacy between the two drugs. The Committee concluded that the current body of evidence does not indicate a difference in the efficacy between methylphenidate IR, dextroamphetamine IR, dexmethylphenidate IR, and mixed amphetamine salts IR.

IR versus once daily stimulant products – The DERP systematic review identified only three studies comparing IR with once daily stimulants that were of sufficient study design quality to evaluate; all three trials compared methylphenidate IR (Ritalin, generics) with methylphenidate OROS (Concerta). One trial [Pelham 2001] enrolling 70 patients found no difference in the teacher rating scale, but reported a statistically significant difference in the parent rating scale that favored Concerta over methylphenidate IR. In a small study assessing driving skills in six adolescents [Cox 2004], there was no difference between the drugs at four to six hours after dosing. However, at 9 to 12 hours after administration, there was a statistically significant difference favoring Concerta. Another study enrolling 282 patients [Wolraich 2001] reported no difference in efficacy. The Oregon systematic review reported that in short-term studies, once daily

Concerta was preferred over methylphenidate IR products. However in trials with a longer duration of evaluation, there was no efficacy difference reported.

Once daily stimulants vs. once daily stimulants – When comparing the once daily products, the different drug release mechanisms influence the timing of effect. Methylphenidate OROS (Concerta) releases 22% of the drug dose immediately followed by release of 78% of the drug over 12 hours. Methylphenidate SODAS (Ritalin LA) releases 50% of the dose immediately and the remaining 50% over an 8- to 9-hour period. The methylphenidate formulation of 30% IR/70% ER beads (Metadate CD) releases 30% of the dose immediately, followed by the remaining 70% over an 8 to 9 hour period.

The drug delivery system appeared to have direct bearing on the results of two studies comparing sustained release products. A trial in 184 patients comparing methylphenidate 30% IR/70% ER (Metadate CD) with methylphenidate OROS (Concerta) [Swanson 2004] used a classroom rating scale as the outcome measure. Metadate CD was superior to Concerta in the morning, and there was no difference between the two drugs in the afternoon. However, in the evening, Concerta was superior to Metadate CD, reflecting the long duration of Concerta via the OROS system.

Methylphenidate OROS (Concerta) was compared to methylphenidate SODAS (Ritalin LA) in a randomized crossover trial enrolling 36 patients [Lopez 2003] using the classroom rating scale. At the four hour assessment time, Ritalin LA 20 mg was superior to 18 mg and 36 mg doses of Concerta. At the eight hour assessment, there was no difference between the Ritalin LA 20 mg and Concerta 36 mg. This study did not include a 12-hour assessment.

Once daily mixed amphetamine salts ER (Adderall XR) was compared to methylphenidate OROS (Concerta) and placebo in a driving assessment test conducted in 35 adolescents [Cox 2006*]*. Concerta compared more favorably to placebo than did mixed amphetamine salts ER (Adderall XR).

Dexmethylphenidate SODAS (Focalin XR) and methylphenidate transdermal system (Daytrana): There are no published trials comparing the efficacy of dexmethylphenidate SODAS (Focalin XR) or methylphenidate transdermal system (Daytrana) with other once daily stimulants; only placebo control trials are available for both products. The pharmacokinetic profiles of both drugs reflect a 12-hour duration of action.

Atomoxetine (Strattera): The DERP systematic review evaluated four studies comparing the non-stimulant atomoxetine (Strattera) and placebo, and reported that atomoxetine was superior to placebo. One trial reported superior efficacy with that atomoxetine compared to methylphenidate IR (Ritalin, generics) [Kratochvil 2002], while another other trial [Sangal 2004] reported no difference in efficacy. Three trials comparing atomoxetine with

either Concerta [Kremmer 2004; Michelson 2004] or Adderall XR [Wigal 2004] showed superior efficacy of the stimulants over atomoxetine.

iii) Treating non-responders – One study evaluating treatment response compared methylphenidate IR (Ritalin, generics) with dextroamphetamine IR (Dexedrine, Dextrostat, generics) [Efron 1997], and concluded that 40% to 80% of patients who did not respond to the initial stimulant would respond to the second stimulant. Clinically, patients who do not respond to a methylphenidate formulation often receive a trial of mixed amphetamine salts IR or ER (Adderall, Adderall XR).

iv) Clinical efficacy conclusion – All stimulant and non-stimulant formulations reviewed, no matter the delivery mechanism, have superior efficacy to placebo. Based on the limited data available, there does not appear to be a difference in efficacy between methylphenidate IR (Ritalin, generics), dextroamphetamine IR (Dexedrine, Dextrostat, generics), dexmethylphenidate IR (Focalin) and mixed amphetamine salts IR (Adderall, generics). Studies comparing IR to once daily methylphenidate products overall yielded no apparent difference in efficacy. The efficacy outcomes of studies comparing once daily methylphenidate products are dependent on the individual release mechanisms of the drugs. Methylphenidate 30% IR/70% ER (Metadate CD) and methylphenidate SODAS (Ritalin LA) showed superior efficacy to methylphenidate OROS (Concerta) at four and eight hour timeframes respectively. Concerta has an efficacy advantage over the other once daily products at the 9-12 hour timeframe. The only products with a sustained 12-hour effect are Concerta, dexmethylphenidate ER (Focalin XR), and methylphenidate transdermal system (Daytrana). The stimulants Concerta and mixed amphetamine salts ER (Adderall XR) appear to have superior efficacy compared to atomoxetine (Strattera).

b) Narcolepsy Drugs

i) Pharmacology

Modafinil (Provigil) – The exact mechanism of action by which modafinil promotes wakefulness is unknown. In contrast to drugs with high addiction potential (e.g., cocaine, amphetamine), modafinil only weakly stimulates receptors in the brain that play a role in reward, pleasure and addiction. This may explain the decreased addiction potential of modafinil compared to other stimulants.

Sodium oxybate (Xyrem) – The exact mechanism of action of sodium oxybate (Xyrem) is unknown. This medication, known chemically as the sodium salt of gamma-hydroxybutyrate (GHB), is similar to gamma-aminobutyric acid (GABA). However, there are distinct GHB receptors in the CNS, where GHB is believed to function as a neurotransmitter and cause marked CNS depression.

ii) FDA-approved indications – Both modafinil (Provigil) and sodium oxybate (Xyrem) are indicated for the treatment of excessive sleepiness associated with narcolepsy. Modafinil (Provigil) is also indicated for the treatment of excessive sleepiness associated with obstructive sleep apnea/hypopnea syndrome (OSAHS) when used as an adjunct to continuous positive airway pressure (CPAP) treatment, and shift-worker sleep disorder (SWSD). Sodium oxybate (Xyrem) is also indicated for the treatment of cataplexy in narcolepsy.

Sodium oxybate (Xyrem) under the moniker of GHB attained notoriety in the 1980s as an illicit drug abused for drug-assisted sexual assault. In 2002, action by the U.S. Congress reclassified the drug as a schedule III product for treatment of narcolepsy. The FDA required a restricted distribution system, the Xyrem Success Program, as a condition for the 2002 approval to reduce the likelihood of diversion for illicit purposes. This program consists of exclusive distribution through a centralized pharmacy, a physician and patient registry, compulsory educational materials for both the physician and the patient, and a tracked method of shipping.

iii) Non-FDA approved indications – Modafinil (Provigil) is used for several conditions that are not approved by the FDA, including ADHD; fatigue associated with chronic diseases (cancer, Parkinson's disease, chronic fatigue syndrome, multiple sclerosis, fibromyalgia); fatigue associated with myotonic dystrophy, idiopathic hypersomnia, or due to antipsychotic or narcotic mediations; augmentation therapy for depression; cocaine dependence; schizophrenia; fatigue related to polio; and several others.

iv) Efficacy

Modafinil (Provigil)

- *Narcolepsy (FDA approved indication):* Four randomized double-blinded placebo controlled trials [US Modafinil in Narcolepsy Multicenter Study Group 1998, 2000; Broughton 1997; Billiard 1994] reported statistically significant improvements in objective and subjective daytime sleepiness. The American Academy of Sleep Medicine rates modafinil as the "standard" of treatment for narcolepsy.
- *Excessive daytime sleepiness associated with OSAHS (FDA approved indication):* Three randomized double-blinded placebo controlled trials evaluated the efficacy of modafinil administered as an adjunct to CPAP treatment [Black 2005, Pack 2005, Kingshott 2001]. In the majority of the patients studied, there were statistically significant improvements (rated both objectively by providers and subjectively by the subjects) in daytime sleepiness.
- *Excessive daytime sleepiness associated with SWSD (FDA approved indication):* Two randomized double-blinded placebo controlled trials [Czeisler 2005, Rosenberg 2003] both showed statistically significant

improvement in objective and subjective measures of fatigue in patients during work-time shifts.

- *Depression (non-FDA approved indication)*: Two randomized double-blinded placebo controlled trials [Fava 2005, Frye 2005] reported statistically significant improvement in objective measures of global improvement. There were improvements in some (but not all) depression-specific rating scales. There was no evidence of increased manic emergence in patients with bipolar depression.
- *Multiple Sclerosis (MS) (non-FDA approved indication)*: One randomized double-blinded placebo controlled trial and one single blinded trial [Stankoff 2005, Rammohan 2002] evaluated efficacy of modafinil for fatigue associated with multiple sclerosis (MS). Stankoff et al showed no statistically significant difference in subjective measures of fatigue and daytime sleepiness. However, Rammohan et al showed a statistically significant improvement in objective measures of fatigue and daytime sleepiness. The National MS Society's expert opinion guideline on management of multiple sclerosis fatigue recommends 200 mg of modafinil daily as a primary treatment of MS fatigue, once secondary causes of fatigue have been addressed.
- *Cocaine dependence (non-FDA approved indication)*: There are two randomized double-blinded placebo controlled trials evaluating use of modafinil to treat cocaine dependency [Dackis 2003, 2005]. One trial showed a statistically significant decrease in self-rated euphoria in treated patients versus placebo. The other trial reported a statistically significant increase in the number of patients who remained abstinent from cocaine abuse for greater than three weeks versus placebo.
- *Myotonic dystrophy (non-FDA approved indication):* Two randomized double-blinded placebo controlled trials [MacDonald 2002, Talbot 2003] showed statistically significant improvements in subjective measures of daytime sleepiness, fatigue, and improvements in subjective quality of life measures.

Sodium oxybate (Xyrem)

- *Excessive daytime sleepiness:* Three randomized, double-blinded placebo controlled trials [Black et al 2006, US Xyrem Multicenter Study Group 2002, 2003] supported the FDA new drug application of sodium oxybate (Xyrem) for excessive daytime sleepiness. All three trials statistically significant improvements in subjective measures of daytime sleepiness with sodium oxybate compared to placebo; in some cases improvements approached normal values. Improvements in sleep quality, alertness, and concentration were also noted.
- *Narcolepsy associated with cataplexy:* Four randomized, double-blinded placebo controlled trials [US Xyrem Multicenter Study Group

2002, 2003, 2005, Scrima 1989] support the use of the drug for narcolepsy associated with cataplexy. All four trials reported statistically significant reductions in the number of cataplexy attacks ranging from 50% to 90%, compared to placebo.

- *Idiopathic hypersomnia:* Two open-label trials [Bastuji 1988, Laffont 1994] showed statistically significant reductions in the number of sleep attacks and daytime drowsiness in most patients treated. This disorder is clinically very similar to narcolepsy, and is diagnosed only through a sleep study by a sleep specialist.

2) Safety and Tolerability

a) ADHD Drugs

i) Black box warning

Stimulants: All the stimulants carry a black box warning of dependence, tolerance and abuse potential. The amphetamines carry a black box warning for sudden cardiac death. An FDA review of the adverse event reporting system concluded that the risk of sudden deaths was not greater than expected, given the large number of people taking the drug. Since the majority of the deaths occurred in children who had structural cardiovascular abnormalities, a warning against using any stimulant in such patients was added to labeling.

Non-stimulant: Atomoxetine (Strattera), which is mechanistically similar to some antidepressants, has a similar black box warning for suicidal ideation.

ii) Contraindications – The stimulants are contraindicated for use in patients with tics, a history of Tourette's syndrome, psychosis, or mania. Stimulants are also contraindicated in patients with significant cardiovascular disease and in patients who experience agitation. Stimulants and atomoxetine (Strattera) are contraindicated in patients who have ingested monoamine oxidase inhibitors (MAOIs) within the last 14 days, and in patients with glaucoma.

iv) Cardiovascular warnings – All the drugs in the ADHD class (both stimulant and non-stimulant) can raise blood pressure (on average by 2-4 mm Hg) and heart rate (on average by 3-6 beats per minute). All the products in the class carry a general warning for patients with underlying cardiac conditions.

v) Hepatotoxicity – Atomoxetine (Strattera) carries a bolded warning for liver injury in the package literature. In over two million treated patients, there have been two cases of significant liver injury. There is currently no recommendation by the manufacturer to monitor liver function in patients treated with atomoxetine.

vi) Decreased growth velocity – Early studies conducted with the stimulants showed a relationship between drug treatment and decreased growth velocity. Decreases in height can range from 0.7 to 1.9 cm in treated patients versus control patients. Long-term studies show trends for treated

patients to catch up with non-treated peers. Labeling for all stimulant products contains strong warnings for continual evaluation of growth velocity in treated patients.

vii) Dermatological reactions – Methylphenidate transdermal system (Daytrana patch) can cause contact sensitization, which is characterized by erythema with an intense local reaction. Rechallenge with the transdermal system may cause skin eruptions, headache, fever and malaise. Data provided by the manufacturer of the transdermal system shows that up to 13% of patients treated with methylphenidate transdermal system may become sensitized to orally administered methylphenidate.

viii) Drug interactions

Stimulants: The stimulants have clinically relevant drug interactions with MAOIs, anticonvulsants, and antidepressants. The body's ability to eliminate the mixed amphetamine salts IR and ER (Adderall, generics; Adderall XR) can be significantly affected by drugs or foods that alkalinize or acidify the urine.

Non-stimulants: Atomoxetine (Strattera) can interact with drugs that inhibit CYP2D6, including paroxetine (Paxil, generics), fluoxetine (Prozac, generics), and quinidine (generics).

ix) Minor adverse events

Stimulants: General adverse events frequently reported during use with any stimulant include delayed sleep onset, headache, decreased appetite, and weight loss. Mixed amphetamine salts IR and ER (Adderall, generics; Adderall XR) have a high percentage of patients who experience irritability and insomnia.

Non-stimulants: Atomoxetine (Strattera) is associated with somnolence, nausea, and vomiting, particularly when dosages are titrated to maximum doses over a few days. Decreased appetite is less of a concern with the atomoxetine than with the stimulants. Patients unable to tolerate adverse effects of the stimulants are often started on therapy with atomoxetine. Atomoxetine is not a controlled drug and is not associated with the same potential for abuse and tolerance as the stimulants.

x) Tolerability

Discontinuation due to adverse effects: Approximately 1%-7% of patients will discontinue ADHD drugs due to adverse events. The most frequently noted adverse events causing discontinuation are irritability, headache, anorexia, nervousness, and agitation.

Persistence: One report [Kenner 2003] comparing the once daily stimulant formulations showed that patients taking methylphenidate OROS (Concerta) and mixed amphetamine salts ER (Adderall XR) took their medication more consistently than patients receiving methylphenidate 30% IR/70% ER (Metadate CD). Another report [Marcus

2005] showed that patients were more persistent with Concerta for longer time periods than methylphenidate IR (Ritalin, generics).

xi) Safety and tolerability conclusion – Major concerns with the stimulants include potential for abuse and tolerance, as well as the potential for sudden cardiac death in patients with underlying structural heart defects. Slowed growth velocity remains an issue with all stimulants. The methylphenidate transdermal system (Daytrana) can cause significant dermatological adverse events and sensitization that can preclude subsequent use of any methylphenidate product. Patients receiving a once daily stimulant may be more persistent with therapy than with IR stimulants.

b) Narcolepsy Drugs

i) Modafinil (Provigil)

Serious adverse events: Three cases of clinically important rashes, including Stevens-Johnson Syndrome (SJS), occurred with modafinil (Provigil) in clinical trials investigating use of the drug for ADHD in children. The FDA adverse event reporting system has received five reports of SJS or erythema multiforme in adults. The new drug application for modafinil (submitted under the trade name Sparlon) for ADHD was denied by the FDA due to these reports.

Addiction potential: Modafinil (Provigil) is a Schedule IV controlled drug. It has not been associated with producing withdrawal symptoms or tolerance.

Drug Interactions: Modafinil (Provigil) undergoes primarily hepatic metabolism; however, there are few clinically significant drug-drug interactions. Absorption of methylphenidate and dextroamphetamine may be delayed by approximately one hour when co-administered with modafinil. Concurrent administration with oral contraceptives containing ethinyl estradiol may result in an 18% reduction in peak concentrations of ethinyl estradiol, thus alternate forms of contraception should be considered in females of child-bearing age.

General adverse events: In the six randomized double-blinded placebo controlled trials performed to obtain FDA approval, the most commonly reported treatment emergent adverse events included headache (34% with modafinil vs. 23% with placebo), nausea (11% with modafinil vs. 3% with placebo), nervousness (7% with modafinil vs. 3% with placebo), and insomnia or anxiety (5% with modafinil vs. 1% with placebo). The percentage of patients discontinuing therapy due to an adverse event was 8% with modafinil-treated patients vs. 3% with placebo-treated patients. Modafinil does not cause clinically significant increases in blood pressure or heart rate, and does not affect sleep architecture.

ii) Sodium oxybate (Xyrem)

Serious adverse events: Sodium oxybate (Xyrem) is a CNS depressant with a high potential for abuse. It carries a black box warning against concomitant use with alcohol or other CNS depressants. In the clinical trials used to gain FDA approval, two deaths were reported due to drug overdoses from ingestion of multiple drugs. Multiple deaths have been reported in association with GHB use, mostly in the setting of intentional abuse with other substances, where it is difficult to determine the exact doses used.

Addiction potential: The drug has demonstrated abuse potential given its properties as a psychoactive drug. A wide range of psychoactive effects have been reported, including dose-dependent sedation/hypnosis.

Drug interactions: Concomitant use of sodium oxybate (Xyrem) with barbiturates, benzodiazepines, and centrally acting muscle relaxants results in additive CNS and respiratory depression. One case report of sodium oxybate taken with methamphetamine resulted in seizure. Use with opioid analgesics and ethanol may result in respiratory depression.

General adverse events: In clinical trials enrolling over 700 patients with narcolepsy, the most commonly reported adverse events were headache (22%), nausea (21%), dizziness (17%), somnolence (8%), vomiting (8%), and enuresis (7%). In these trials, 10% of patients discontinued sodium oxybate (Xyrem) therapy due to adverse events (compared to 1% with placebo), most commonly due to nausea, dizziness, or vomiting (each occurring with a 2% incidence).

3) Other Factors

a) ADHD Drugs

i) Pregnancy/Lactation – All of the ADHD drugs are rated as pregnancy category C. The amphetamines and atomoxetine (Strattera) are excreted in breast milk. It is not known whether methylphenidate products are excreted in breast milk.

ii) Pediatrics – The FDA has approved the use of the ADHD drugs in patients down to the age of six years. Dextroamphetamine (Dexedrine, Dextrostat, generics) is labeled for use in patients as young as three years of age.

iii) Renal and hepatic dysfunction – Dosage adjustments are not required for any of the ADHD drugs in patients with renal failure. In patients with hepatic impairment, only atomoxetine (Strattera) requires dosage adjustment.

iv) Dosage formulations – The methylphenidate transdermal system (Daytrana) is the only non-oral formulation in this class. Methylphenidate 30% IR/70% ER (Metadate CD), mixed amphetamine salts ER (Adderall XR), dexmethylphenidate SODAS (Focalin XR) and methylphenidate SODAS (Ritalin LA) are capsule formulations that can be opened and sprinkled on

food for patients with swallowing difficulties. Methylphenidate IR (Methylin) is available in an oral solution and chewable tablets.

v) One survey [Wilens 2004] of students taking stimulant medications for ADHD treatment reported that 22% of patients escalated doses, with 10% escalating doses specifically for euphoric effects. Also of note, 11% of the students sold their medication to peers. Another survey [Teter 2006] of college students taking stimulant medication found that mixed amphetamine salts IR and ER (Adderall, generics; Adderall XR) were the most frequently abused products. A concerning finding was that the stimulants were crushed and snorted for their euphoric effects. Respondents also used the stimulants for weight loss and to increase concentration for studying.

vi) MTF provider opinion and clinical coverage: A total of 214 MTF providers responded to an opinion survey. All responders desired the availability of a long-acting methylphenidate product; providers specifically preferred methylphenidate OROS (Concerta). Providers prescribed Concerta more frequently than mixed amphetamine salts ER (Adderall XR) or atomoxetine (Strattera) when initiating therapy. However, providers requested availability of both Adderall XR and atomoxetine as therapeutic options for patients intolerant of or not responding to methylphenidate products. A methylphenidate IR product was also requested. Providers were not familiar with and did not prescribe the methylphenidate transdermal system (Daytrana), dexmethylphenidate IR and SODAS (Focalin, Focalin XR), and methamphetamine IR (Desoxyn, generics).

Survey responders stated that in addition to the current BCF agents, most pharmacies stocked methylphenidate SR (Ritalin SR) and about half the pharmacies stocked atomoxetine (Strattera). The most requested non-formulary agent was atomoxetine, followed by long-acting methylphenidate 30% IR/70% ER (Metadate CD.)

vii) Other Factors Conclusion: All the products in the ADHD class are rated pregnancy category C. All the products are indicated for use in pediatric patients. The dose of atomoxetine (Strattera) must be adjusted in patients with hepatic insufficiency. There are multiple products available for patients who have difficulty swallowing a tablet or capsule. The stimulants have significant abuse potential. MTF providers desired availability of a long-acting methylphenidate product, preferably methylphenidate OROS (Concerta); an IR methylphenidate product; mixed amphetamine salts ER (Adderall XR); and atomoxetine.

b) Narcolepsy agents

i) Modafinil (Provigil): Modafinil (Provigil) has not been evaluated in patients older than 65 years of age or younger than 16 years of age. The dosage should be decreased in patients with severe hepatic impairment.

ii) Sodium oxybate (Xyrem): Sodium oxybate is primarily metabolized in the liver; patients with hepatic insufficiency require dosage reduction by 50%. No dosage adjustment is necessary in patients with renal insufficiency. There is no clinical trial experience with patients over the age of 65 or under 16 years of age.

ADHD and Narcolepsy Overall Clinical Effectiveness Conclusion – The P&T Committee concluded that:

1) For ADHD, interpretation of the data is limited due to the poor quality of studies, limited number of comparator trials, varying rating scales used, small number of patients enrolled, and short study duration.

2) There is no evidence to suggest a difference in efficacy between IR formulations of methylphenidate (Ritalin, generics), dextroamphetamine (Dexedrine, Dextrostat, generics), dexmethylphenidate (Focalin), and mixed amphetamine salts (Adderall, generics).

3) The overall efficacy of the once daily methylphenidate formulations appears similar based on a few small studies, but differences exist in reported outcomes at specific times of the day, due to the individual release mechanisms of the products. Methylphenidate 30% IR/70% ER (Metadate CD) and methylphenidate SODAS (Ritalin LA) are eight- to nine-hour products, while methylphenidate OROS (Concerta), dexmethylphenidate SODAS (Focalin XR), and methylphenidate transdermal system (Daytrana) are 12-hour products.

4) Mixed amphetamine salts ER (Adderall XR) appears to have similar efficacy to methylphenidate OROS (Concerta), based on one small study.

5) The efficacy of atomoxetine (Strattera) appears to be inferior to the stimulants, but it is the only non-stimulant available in the ADHD class.

6) Between 40% and 80% of patients who do not respond to one type of stimulant (methylphenidate products vs. amphetamine products) may respond to the other.

7) The adverse events and warnings of the stimulants are well-recognized and are similar between products.

8) The methylphenidate transdermal system (Daytrana) can cause significant dermatological adverse events, which can lead to sensitization to oral products.

9) Atomoxetine (Strattera) remains the only alternative for patients who cannot tolerate stimulants, despite its association with an increased risk of hepatotoxicity and suicidal ideation.

10) Several products can be sprinkled on food for patients with swallowing difficulties.

11) Responders to a provider survey expressed a desire for availability of the following products to cover clinical needs: methylphenidate OROS, an IR methylphenidate product, mixed amphetamine salts ER, and atomoxetine.

12) The narcolepsy drug modafinil (Provigil) fills a unique niche in therapy as a wakefulness promoting agent.

13) The narcolepsy drug sodium oxybate (Xyrem) has a high incidence of adverse events, but fills a unique niche in therapy for cataplexy. The manufacturer's restricted distribution program limits use to appropriate patients.

14) Based on clinical issues alone, there are no reasons to designate any of the ADHD drugs or narcolepsy drugs as non-formulary under the UF.

COMMITTEE ACTION – The P&T Committee voted (16 for, 0 opposed, 0 abstained, 1 absent) to accept the clinical effectiveness conclusions stated above.

B. ADHD and Narcolepsy Agents – Relative Cost Effectiveness

The P&T Committee evaluated the relative cost-effectiveness of the ADHD and narcolepsy agents in relation to efficacy, safety, tolerability, and clinical outcomes of the other agents in the class. Information considered by the P&T Committee included, but was not limited to, sources of information listed in 32 CFR 199.21(e)(2).

The cost-effectiveness review was conducted on subclasses based on each agent's indication for treatment (ADHD or narcolepsy). Drugs evaluated in the ADHD subclass were further grouped by duration of action. This process of categorization left three subclasses:

1) A once daily use subclass of ADHD products including mixed amphetamine salts ER (Adderall XR), atomoxetine (Strattera), dexmethylphenidate SODAS (Focalin XR), methylphenidate OROS (Concerta), methylphenidate 30% IR/70% ER (Metadate CD), methylphenidate SODAS (Ritalin LA), and methylphenidate transdermal system (Daytrana).

2) A multiple daily use subclass of ADHD products including mixed amphetamine salts IR (Adderall, generics), dexamphetamine IR (Dexedrine, Dextrostat, generics), dexmethylphenidate IR (Focalin), methamphetamine IR (Desoxyn, generics), methylphenidate IR (Ritalin, generics), and methylphenidate sustained-release (Ritalin SR).

3) A subclass of drug products indicated for narcolepsy including mixed amphetamine salts IR (Adderall, generics), dexamphetamine IR (Dexedrine, Dextrostat, generics), methylphenidate IR (Ritalin, generics), modafinil (Provigil), and sodium oxybate (Xyrem).

The choice of cost-effectiveness analysis for each subclass was based on the findings from the clinical effectiveness review. The results of the clinical review showed evidence of differences among the drugs in the once daily use subclass in regards to efficacy. However, there was insufficient evidence to conclude that the multiple daily use and narcolepsy subclasses differed based on efficacy, safety, tolerability, or clinical outcomes. In light of these conclusions, the cost-effectiveness analyses were conducted as follows: (1) cost-utility analysis of the once daily use subclass; (2) cost-minimization analysis of the multiple daily use subclass; and (3) cost-minimization analysis of the drugs indicated for the treatment of narcolepsy.

1) The cost-utility analysis compared the costs per quality-adjusted life year (QALY) among the once daily use products. The results showed methylphenidate OROS (Concerta) to be the most cost-effective agent in this subclass. The mixed

amphetamine salts ER (Adderall XR) and methylphenidate 30% IR/70% ER (Metadate CD) also performed well with similar cost-effectiveness ratios. Atomoxetine (Strattera) was cost-effective under a scenario assuming greater patient preference for a non-stimulant once daily use product. Dexmethylphenidate SODAS (Focalin XR) and methylphenidate transdermal system (Daytrana) were not cost-effective relative to the other agents in the subclass.

2) The cost-minimization analysis of the multiple daily use products compared the weighted average cost per day of treatment across all three points of service for each drug product. The results revealed that most products were cost-effective, with methylphenidate IR (Ritalin, generics) being the most cost-effective agent in this subclass. Dexmethylphenidate IR (Focalin) was less cost-effective than other agents in this subclass. Furthermore, the absence of a compelling clinical rationale for inclusion on the UF suggested dexmethylphenidate IR should be evaluated for non-formulary status.

3) The cost-minimization analysis for the drug products indicated in the treatment of narcolepsy compared the weighted average cost per day of treatment across all three points of service for mixed amphetamine salts IR (Adderall, generics), dexamphetamine IR (Dexedrine, Dextrostat, generics), methylphenidate IR (Ritalin, generics), and modafinil (Provigil). Sodium oxybate (Xyrem) also was included and evaluated at its cost per day of treatment in the retail point of service only, since it is not available at the other points of service due to its controlled distribution system. The results showed that methylphenidate IR was the most cost-effective agent in the treatment of narcolepsy, followed closely by dexamphetamine IR and mixed amphetamine salts IR. Sodium oxybate and modafinil, although more costly per day of treatment relative to the other drugs in this subclass, possessed unique clinical advantages justifying their inclusion on the Uniform Formulary. Modafinil has a unique niche for wakefulness promotion in a variety of disorders (as described in the clinical review) and sodium oxybate has proven efficacy for narcolepsy complicated by cataplexy.

Based on the results of the clinical review and the pharmacoeconomic evaluations, a budget impact analysis (BIA) of various formulary scenarios was conducted to estimate the influence of other factors associated with a UF decision (i.e., market share migration, switch costs, non-formulary cost shares). The goal of the BIA was to aid the Committee in determining which group of ADHD/narcolepsy drugs best met the majority of the clinical needs of the DOD population at the lowest expected cost to the MHS.

Cost Effectiveness Conclusion

1) Once daily ADHD agents: dexmethylphenidate SODAS (Focalin XR) and methylphenidate transdermal system (Daytrana) were not cost-effective relative to the other agents in the subclass.

2) Multiple daily use ADHD agents: dexmethylphenidate IR (Focalin) was not cost-effective relative to the other agents in the subclass.

Agents indicated in the treatment of narcolepsy:

1) Although modafinil (Provigil) and sodium oxybate (Xyrem) were more costly relative to the other agents in the subclass, they possessed unique clinical advantages relative to other agents indicated for the treatment of narcolepsy.

2) The UF scenario that included dexmethylphenidate IR (Focalin), dexmethylphenidate SODAS (Focalin XR), and methylphenidate transdermal system (Daytrana) as non-formulary under the UF best met the majority of the clinical needs of the DOD population at the lowest expected cost to the MHS and was the most cost-effective UF scenario.

COMMITTEE ACTION – The P&T Committee voted (16 for, 0 opposed, 0 abstained, 1 absent) to accept the cost-effectiveness conclusions stated above.

C. ADHD and Narcolepsy Agents – UF Recommendations

COMMITTEE ACTION – Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of the ADHD and Narcolepsy agents, and other relevant factors, the P&T Committee, based upon its collective professional judgment, voted (15 for, 0 opposed, 0 abstained, 2 absent) to recommend that mixed amphetamine salts IR (Adderall, generics), mixed amphetamine salts ER (Adderall XR), atomoxetine (Strattera), dexamphetamine IR (Dexedrine, Dextrostat, generics), methamphetamine IR (Desoxyn, generics), methylphenidate 30% IR/70% ER (Metadate CD), methylphenidate IR (Ritalin, generics), methylphenidate OROS (Concerta), methylphenidate SODAS (Ritalin LA), methylphenidate SR (Ritalin SR), modafinil (Provigil), and sodium oxybate (Xyrem) be maintained as formulary on the UF and that dexmethylphenidate IR (Focalin), dexmethylphenidate SODAS (Focalin XR), methylphenidate transdermal system (Daytrana) be classified as non-formulary under the UF.

D. ADHD and Narcolepsy Agents – Medical Necessity Criteria

Based on the clinical evaluation for methylphenidate transdermal system (Daytrana), dexmethylphenidate IR (Focalin) and dexmethylphenidate SODAS (Focalin XR), and the conditions for establishing medical necessity for a non-formulary medication provided for in the UF rule, the P&T Committee recommended the following general medical necessity criteria for methylphenidate transdermal system (Daytrana), dexmethylphenidate IR (Focalin), and dexmethylphenidate SODAS (Focalin XR):

1) Use of formulary alternatives is contraindicated.

2) The patient has experienced or is likely to experience significant adverse effects from formulary alternatives.

3) Use of formulary alternatives has resulted in therapeutic failure.

4) No formulary alternative is available.

The P&T Committee noted that criterion #4 would apply only to the use of methylphenidate transdermal system (Daytrana) by patients who require treatment with a once daily methylphenidate product, but who are unable to take oral medication.

COMMITTEE ACTION: The P&T Committee voted (15 for, 0 opposed, 0 abstained, 2 absent) to approve the medical necessity criteria outlined above.

E. ADHD and Narcolepsy Agents – UF Implementation Period

Because of the small number of unique utilizers affected (approximately 3,000 patients out of approximately 175,000 unique utilizers at all three POS), the P&T Committee recommended an effective date of the first Wednesday following a 90-day implementation period. The implementation period will begin immediately following approval by the Director, TMA.

MTFs will not be allowed to have methylphenidate transdermal system (Daytrana), dexmethylphenidate IR (Focalin), or dexmethylphenidate SODAS (Focalin XR) on their local formularies. MTFs will be able to fill non-formulary requests for these agents only if both of the following conditions are met: 1) the prescription must be written by a MTF provider, and 2) medical necessity is established. MTFs may (but are not required to) fill a prescription for a non-formulary ADHD agent written by a non-MTF provider to whom the patient was referred, as long as medical necessity has been established.

COMMITTEE ACTION: The P&T Committee recommended (15 for, 0 opposed, 0 abstained, 2 absent) an effective date of the first Wednesday following a 90-day implementation period. The implementation period will begin immediately following the approval by the Director, TMA.

F. ADHD and Narcolepsy Agents – Basic Core Formulary (BCF) Review and Recommendations – The P&T Committee had previously determined that two once daily use products and one or more multiple daily use products should be added to the BCF based on the clinical and cost effectiveness review. As a result of the clinical and economic evaluations presented, the P&T Committee recommended that the BCF remain unchanged with mixed amphetamine salts ER (Adderall XR), methylphenidate OROS (Concerta), and methylphenidate IR (Ritalin, generics) on the BCF. Concerta has high utilization due to current BCF status, is a methylphenidate product with a 12-hour duration, and was determined to be the most cost-effective once daily methylphenidate product. Similarly, Adderall XR has high utilization at the MTFs; is an amphetamine product with a 12-hour duration, and was cost-effective relative to the other agents in the subclass. Methylphenidate IR is extremely cost-effective, is available in a generic formulation, and allows for dose titration.

COMMITTEE ACTION – The P&T Committee voted (15 for, 0 opposed, 0 abstained, 2 absent) to recommend retaining mixed amphetamine salts ER (Adderall XR), methylphenidate OROS (Concerta), and methylphenidate IR (Ritalin) as the BCF selections in this class.

8. PRIOR AUTHORIZATION (PA) REQUIREMENT FOR MODAFINIL (PROVIGIL)

Modafinil (Provigil) is approved by the FDA for treatment of excessive daytime sleepiness associated with narcolepsy, excessive daytime sleepiness associated with obstructive sleep apnea/hypopnea syndrome (OSAHS) when used as an adjunct to continuous positive airway pressure (CPAP) treatment, and excessive daytime sleepiness associated with shift-worker sleep disorder (SWSD). There are numerous off-label uses for the drug.

Modafinil (Provigil) accounted for approximately $24 million in DoD expenditures in FY 06. Given the rapid increase in use and expenditures, a DoD-specific analysis of modafinil utilization was performed. Among unique utilizers of modafinil, as many as 44% of the total prescriptions appeared to be written for indications not supported by well-controlled studies with clinically meaningful endpoints that are published in refereed medical literature. Given the increasing use of modafinil for off-label indications not well established by the medical literature, the Committee agreed that a PA should be required for modafinil.

Taking into consideration the clinical review recommendation that modafinil (Provigil) require a PA, a threshold analysis was conducted to estimate the relationship between the administrative costs of conducting a PA policy and the cost-offset from reduced utilization of modafinil secondary to the policy. The results suggested that the administrative costs of a PA requirement for modafinil would not be cost-prohibitive.

The P&T Committee identified five off-label indications, in addition to the three FDA-approved indications, as supportable based on published clinical evidence or recommendations from nationally recognized expert organizations, based on guidelines from the TRICARE Policy Manual 6010.54 (August 2002) chapter 1 section 2.1 regarding coverage of unproven drugs, devices, medical treatments and procedures. With respect to the off-label uses, clinical evidence supports use of modafinil (Provigil) for augmentation of treatment for major depression, fatigue associated with multiple sclerosis (MS), augmentation of primary cognitive-behavioral therapy in acute rehabilitation of cocaine dependence, fatigue associated with myotonic dystrophy, and fatigue associated with idiopathic hypersomnia. Other off-label uses (e.g., in chronic fatigue syndrome, stroke rehabilitation, appetite suppression, Parkinson's disease and others) are supported only by case reports, uncontrolled trials, single-blinded trials, or chart reviews, which constitute insufficient evidence to establish efficacy and safety per TRICARE regulations. The PEC will continue to monitor the clinical literature on an ongoing basis for evidence that may justify revision of these criteria.

COMMITTEE ACTION – Based on its increasing use for off-label indications not well established by the medical literature, the P&T Committee recommended that a PA be required for modafinil (Provigil) (15 for, 0 against, 0 abstained, 2 absent). The Committee recommended that the PA should have an effective date of the first Wednesday following a 90-day implementation period, consistent with the recommended implementation period for non-formulary medications in the ADHD and narcolepsy agents class. The implementation period will begin immediately following the approval by the Director, TMA.

The Committee agreed that the following PA criteria should apply (15 for, 0 against, 0 abstained, 2 absent). PA approval would be good for one year. The P&T Committee noted that the PA is not intended to apply to modafinil (Provigil) use in Active duty operational/readiness situations based on established protocols; MTFs should make necessary allowances for such use.

1) Narcolepsy
2) OSAHS, only after adequate titration of CPAP treatment
3) SWSD, only in patients who work night shifts
4) MS, only after secondary causes of fatigue have been addressed

5) Myotonic dystrophy

6) Depression, only after primary therapy has failed and if the use of other stimulant augmentation is contraindicated

7) Idiopathic hypersomnia diagnosed by a sleep specialist

8) Cocaine dependence when approved by a DoD substance abuse program

9. PRIOR AUTHORIZATION (PA) REQUIREMENT FOR FENTANYL PATCHES (DURAGESIC, GENERICS)

Based on the following considerations, the P&T Committee agreed that a PA should be required for fentanyl patches (Duragesic, generics).

- Fentanyl, a strong opioid narcotic, can cause severe respiratory depression in patients who are not tolerant to opioids. Product labeling for fentanyl patches was strengthened in July 2005 following reports of serious adverse events and fatalities. Fentanyl patches are indicated for management of persistent, moderate to severe chronic pain requiring continuous, around-the-clock administration for an extended period of time, that cannot be managed by other means, and ONLY in patients who are already receiving opioids, have demonstrated opioid tolerance, and require a total daily dose at least equivalent to fentanyl 25 mcg/hr. They should not be used for management of acute pain or short periods of opioid analgesia; post-op pain, including outpatient/day surgeries; mild pain; or intermittent pain.
- Warnings concerning safe use of fentanyl patches have been issued by various organizations, including the DoD Patient Safety Center, the FDA, and the Institute of Safe Medication Practices. On 31 July 2006, in response to reports of improper use of fentanyl patches, the Air Force established a policy restricting the prescription of fentanyl patches to pain specialists and other authorized providers and requiring drug utilization review by each facility. Pharmacists are required to review all fentanyl patch prescriptions to verify that:
  - Fentanyl is being prescribed for management of chronic pain.
  - The patient has already received opioid therapy, and requires a total daily dose at least equivalent to fentanyl 25mcg/h.
  - Fentanyl is NOT being prescribed for intermittent (prn) pain.
  - The patient is 2 years of age or older.
  - The patient is NOT receiving both fentanyl and potent CYP3A4 inhibitors (ritonavir, ketoconazole, itraconazole, troleandomycin, clarithromycin, nelfinavir, or nefazodone).

- Modifications to the Pharmacy Data Transaction Service (PDTS) scheduled for completion by December 2006 will add the capability of "looking back" at a given patient's profile for the presence or absence of prescription fills for specific medications within a defined time period. This will allow the fentanyl PA to be targeted only to patients who may not be opioid-tolerant based on prior patterns of opioid use and limit the administrative impact of the PA on patients receiving fentanyl patches on a chronic basis.

COMMITTEE ACTION – Based on safety concerns, the P&T Committee recommended that a PA be required for fentanyl patches (15 for, 0 against, 0 abstained, 2 absent). The Committee recommended that the PA should have an effective date no sooner than the first Wednesday following a 30-day implementation period, but as soon thereafter as possible based on availability of the automated PA capability in PDTS. The implementation period will begin immediately following approval by the Director, TMA.

The P&T Committee agreed that the following general PA criteria should apply (15 for, 0 against, 0 abstained, 2 absent), based on requirements in product labeling. Patients meeting the automated PA criteria would not be required to have their providers submit any additional information. PA requirements will apply to each prescription (note, however, that a patient receiving fentanyl patches on a chronic basis would meet automated PA criteria for each prescription).

1) Automated PA criteria:

- Patient is likely to be opioid-tolerant based on the pattern of opioid use in the patient's profile during a defined "look-back" period

2) PA criteria if automated criteria are not met:

- Patient is likely to be opioid-tolerant based on prior opioid use not captured by PDTS (e.g., medications started on an inpatient basis or prescriptions filled outside the DoD pharmacy benefit) AND
- Patient requires a fentanyl patch for treatment of persistent, moderate to severe chronic pain requiring continuous, around-the-clock administration for an extended period of time that cannot be managed by other means and NOT for management of acute pain or short periods of opioid analgesia, post-op pain (including outpatient/day surgeries), mild pain, or intermittent pain.

10. CLASS OVERVIEWS

Portions of the clinical reviews for each of the following classes were presented to the Committee: Topical Glaucoma Agents, Narcotic Analgesics, Angiotensin Receptor Blockers (ARBs), Growth Stimulant Agents, MAOI Antidepressants, 5-Alpha Reductase Inhibitors, 5-HT Receptor Agonists ("Triptans"), Antilipidemics II (LIP-2s), and (Proton Pump Inhibitors (PPIs).

The Committee provided expert opinion regarding those clinical outcomes considered most important for the PEC to use in completing the clinical effectiveness review and developing the appropriate cost effectiveness models. The clinical and economic analyses of these classes will be completed during the February 2007 or May 2007 meetings; no action is necessary.

11. ADJOURNMENT

The second day of the meeting adjourned at 1430 hours on 15 November 2006. The dates of the next meeting are 13-15 February 2007.

*The topical antifungal drug class excludes vaginal products and products for onychomycosis (e.g., ciclopirox topical solution [Penlac])

Appendix B – Table 2. Newly Approved Drugs. November 2006 DoD P&T Committee Meeting

Medication (Brand name; manufacturer) mechanism of action	**FDA Approval Date & FDA-Approved Indications**	**Committee Recommendation**
Insulin Human (rDNA origin) Inhalation Powder (Exubera; Pfizer/Nektar Therapeutics) inhaled insulin	Jan 06 ▪ For control of hyperglycemia in adults with type 1 diabetes in conjunction with long-acting ▪ For control of hyperglycemia in adults with type 2 diabetes either as monotherapy, or in combination with oral agents or long-acting insulin	No UF recommendation at this meeting. Consideration of UF status deferred until insulins are reviewed.
Fentanyl buccal tablet (Fentora; Cephalon) narcotic analgesic	Sep 06 ▪ Management of breakthrough pain in patients with cancer who are already receiving and who are tolerant to opioid therapy for their underlying persistent cancer pain. ▪ Patients considered opioid tolerant are those who are taking at least 60 mg of morphine/day, at least 25 mcg of transdermal fentanyl/hour, at least 30 mg of oxycodone daily, at least 8 mg of hydromorphone daily, or an equianalgesic dose or another opioid for a week or longer.	No UF recommendation at this meeting. Consideration of UF status deferred until narcotic analgesics are reviewed; scheduled for Feb 07.
Posaconazole oral suspension (Noxafil; Schering-Plough) oral antifungal agent	Sep 06 ▪ Prophylaxis of invasive Aspergillus and Candida infections in patients 13 years of age and older who are at high risk of developing these infections due to being severely immunocompromised, such as hematopoietic stem cell transplant recipients with graft-versus-hose disease, or those with hematologic malignancies with prolonged neutropenia from chemotherapy ▪ Treatment of oropharngeal candidiasis, including infections refractory to itraconazole and /or fluconazole	No UF recommendation at this meeting. Consideration of UF status deferred until oral antifungal medications are reviewed.
Drosperinone / estradiol 0.5 mg/1 mg (Angeliq; Berlex) hormonal replacement therapy	Sep 05 (launched Oct 06) Indicated in women who have a uterus for the: ▪ Treatment of moderate to severe vasomotor symptoms associated with the menopause. ▪ Treatment of moderate to severe symptoms of vulvar and vaginal atrophy associated with the menopause. When prescribing solely for the treatment of symptoms of vulvar and vaginal atrophy, topical vaginal products should be considered.	No UF recommendation at this meeting. Consideration of UF status deferred until hormonal replacement therapies are reviewed

DECISION PAPER

DEPARTMENT OF DEFENSE

PHARMACY AND THERAPEUTICS COMMITTEE RECOMMENDATIONS

August 2006

1. CONVENING

2. ATTENDANCE

3. REVIEW MINUTES OF LAST MEETING

4. ITEMS FOR INFORMATION

5. REVIEW OF RECENTLY APPROVED AGENTS

The P&T Committee was briefed on five new drugs that were approved by the Food and Drug Administration. None of the medications fall into drug classes already reviewed by the P&T Committee, therefore Uniform Formulary (UF) consideration was deferred until the corresponding drug class reviews are completed. The Committee reviewed one new drug for quantity limits, dasatinib (Sprycel), which is an oral multi-kinase inhibitor approved for treatment of patients with chronic myeloid leukemia or Philadelphia chromosome-positive acute lymphoblastic leukemia. The Committee agreed that quantity limits were needed for dasatinib, based on the risk of discontinuation of therapy, the probability that dosage adjustments requiring changes in tablet strength will be needed, potential for drug interactions, and variable patient response to therapy and drug-related adverse effects. Other oral chemotherapy drugs also have quantity limits.

COMMITTEE ACTION: The DoD Pharmacy and Therapeutics (P&T) Committee voted (17 for, 0 opposed, 0 abstained, 0 absent) to recommend quantity limits for dasatinib in the TRICARE Mail Order Pharmacy (TMOP) Program of 90 tablets for the 70 mg strength, 180 tablets for the 50 mg strength, and 180 tablets for the 20 mg strength per 45 days, with a days supply limit of 45 days (not collective across strengths). In the TRICARE Retail Pharmacy Network (TRRx), the recommended quantity limits were 60 tablets for the 70 mg strength, 120 tablets for the 50 mg strength, and 120 tablets for the 20 mg strength per 30 days, with a days supply limit of 30 days (not collective across strengths). (See page 14 of the P&T Committee minutes.)

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

6. PRIOR AUTHORIZATION (PA) REQUIREMENT FOR EXENATIDE (BYETTA)

The Committee agreed that a PA was needed for exenatide subcutaneous injection due to the potential for inappropriate use.

COMMITTEE ACTION: Based on exenatide's potential use for indications not covered by TRICARE (i.e., weight loss) and/or not supported by clinical evidence, the P&T Committee recommended (14 for, 1 against, 0 abstained, 2 absent) that PA be required for exenatide. The criteria recommended by the P&T Committee incorporate modifications to the Pharmacy Data Transaction Service (PDTS) that will allow automation of some PA criteria, reducing paperwork burden and cost. These modifications are scheduled for completion by December 2006. (See pages 14-16 of the P&T Committee minutes for rationale and summary of PA criteria.)

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

COMMITTEE ACTION: The Committee recommended (14 for, 1 against, 0 abstained, 2 absent) that the PA for exenatide should have an effective date no sooner than the first Wednesday following a 30-day implementation period, but as soon thereafter as possible based on availability of the automated PA capability in PDTS. The implementation period will begin immediately following the approval by the Director, TRICARE Management Activity (TMA). (See pages 14-16 of the P&T Committee minutes.)

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

7. THIAZOLIDINEDIONE (TZD) DRUG CLASS REVIEW

The P&T Committee evaluated the relative clinical effectiveness and cost-effectiveness of the TZD drugs marketed in the United States. The drugs in this class include the parent compounds rosiglitazone (Avandia) and pioglitazone (Actos); their respective combinations with metformin, rosiglitazone/metformin (Avandamet) and pioglitazone/metformin (Actoplus Met); and one combination of a TZD with a sulfonylurea, rosiglitazone/ glimepiride (Avandaryl). The TZDs accounted for approximately $110 million dollars in Fiscal Year (FY) 2005 and are ranked 12th in Military Health System (MHS) drug class expenditures.

The Committee voted (16 for, 0 opposed, 1 abstained, 0 absent) that:

1) Neither rosiglitazone nor pioglitazone appears less effective in reducing elevated hemoglobin A1c or fasting plasma glucose values.

2) There is insufficient evidence to determine if there are significant differences between the two parent compounds in the prevention of microvascular or macrovascular complications of diabetes.

3) Neither rosiglitazone nor pioglitazone appears less likely to cause hepatotoxicity, congestive heart failure, weight gain, edema, decreased blood pressure, hypoglycemia, or reduced hemoglobin and hematocrit.

4) Safety and tolerability differences appear to be limited to the potential for more drug interactions with pioglitazone.

5) Rosiglitazone appears to have a less favorable effect on lipid parameters than pioglitazone, however the clinical significance of this is unknown.

6) There are only minor differences between the two TZDs based on dosing frequency and receptor binding – provider opinion was split between preferring pioglitazone and no preference.

7) Neither rosiglitazone nor pioglitazone – or their respective combination products – appears sufficiently less clinically effective than the other to warrant classification as non-formulary under the UF based on clinical issues alone.

Based on the results of the cost-effectiveness analysis (CEA) and other clinical and cost considerations, the Committee concluded (16 for, 0 opposed, 1 abstained, 0 absent) that the UF scenario that maintained rosiglitazone, pioglitazone, rosiglitazone/metformin, pioglitazone/metformin, and rosiglitazone/glimepiride on the UF formulary was the most cost effective UF scenario.

A. COMMITTEE ACTION: UF RECOMMENDATION – Taking into consideration the conclusions from the relative clinical effectiveness and the relative cost effectiveness determinations for the TZD drugs, and other relevant factors, the P&T Committee voted (13 for, 1 opposed, 2 abstained, 1 absent) to recommend that rosiglitazone, pioglitazone, rosiglitazone/metformin, pioglitazone/metformin, and rosiglitazone/glimepiride be maintained as formulary on the UF and that no agents from this class be classified as non-formulary under the UF. (See paragraphs 7A and 7B on pages 16-23 of the P&T Committee minutes.)

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

B. COMMITTEE ACTION: BASIC CORE FORMULARY (BCF) RECOMMENDATION – Based on the relative clinical and cost-effectiveness analysis, the P & T Committee voted (13 for, 1 opposed, 3 abstained, 0 absent) to recommend retaining rosiglitazone and rosiglitazone/metformin as the BCF selections in this class. The Committee did not recommend addition of rosiglitazone/metformin to the BCF. (See paragraph 7E on page 23 of the P&T Committee minutes for rationale.

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

8. HISTAMINE-2 (H2) ANTAGONISTS AND OTHER GASTROINTESTINAL (GI) PROTECTANT AGENTS DRUG CLASS REVIEW

The P&T Committee evaluated the relative clinical effectiveness of the H2 antagonists and other GI protectant agents. The drug class comprises: the four H2 antagonists, ranitidine (Zantac, generics), cimetidine (Tagamet, generics), famotidine (Pepcid, generics), and nizatidine (Axid, generics); the prostaglandin analog misoprostol (Cytotec, generics); and the mucosal protectant sucralfate (Carafate, generics). These six drugs have been marketed for several years, and all are available in generic formulations. This drug class accounted for $10.9 million in FY 2005, and is ranked 75th in MHS drug class expenditures.

The Committee voted (16 for, 0 opposed, 1 abstained, 0 absent) that:

1) The four H2 antagonists ranitidine, cimetidine, famotidine, and nizatidine are widely considered interchangeable for treatment of gastroesophageal reflux disease, peptic ulcer disease, and *H. pylori* infections, despite differences in potency, duration of action, and onset of action.
2) Compared to the other three H2 antagonists, cimetidine has evidence for use in non-gastrointestinal conditions.
3) Ranitidine is the most widely used H2 antagonist across the MHS, is dosed once or twice daily, has a low potential for drug interactions, and is available in an oral syrup for pediatric patients.
4) Famotidine and nizatidine have similar dosing intervals, drug interaction profiles and formulations as ranitidine, but are less frequently prescribed in the MHS.
5) Cimetidine is more difficult to use clinically compared to the other three H2 antagonists due to its need for multiple daily dosing (BID-QID) and drug interaction profile.
6) Misoprostol serves a unique niche for use in high risk patients for non-steroidal anti-inflammatory drug (NSAID)-induced ulcers, despite its adverse effect profile and warnings in women of child bearing age.
7) Sucralfate has a unique mechanism of action (physical barrier formation) and offers an alternative to proton pump inhibitors and H2 antagonists for stress ulcer prophylaxis.

Based on the results of the cost analysis and other clinical and cost considerations, the P&T Committee voted (17 for, 0 opposed, 0 abstained, 0 absent) that: (1) ranitidine was the most cost effective H2 antagonist; (2) two other H2 antagonists, famotidine and cimetidine, were shown to have similar relative cost-effectiveness compared to ranitidine; (3) nizatidine was found to be slightly more costly compared to the other generic H2 antagonists, due to recent

availability of the generic version; and (4) misoprostol and sucralfate are available in generic versions and have an established niche in therapy for select patients.

A. COMMITTEE ACTION: UF RECOMMENDATION – Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations, and other relevant factors, the P&T Committee voted (17 for, 0 opposed, 0 abstained, 0 absent) to recommend that the H2 antagonists ranitidine, cimetidine, famotidine and nizatidine; the prostaglandin analog misoprostol; and the mucosal protective agent sucralfate should be maintained as formulary on the UF, and that no agents from this class be classified as non-formulary under the UF. (See paragraphs 8A and 8B on pages 23-27 of the P&T Committee minutes).

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

B. COMMITTEE ACTION: BCF RECOMMENDATION – Based on the relative clinical and cost effectiveness analyses, the P&T Committee voted (17 for, 0 opposed, 0 abstained, 0 absent) to recommend retaining ranitidine as the BCF selection in this class, excluding the effervescent tablet and gel-filled capsule formulations. (See paragraph 8E on page 27 of the P&T Committee minutes for rationale.)

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

9. ANTILIPIDEMIC I (LIP-I) AGENTS DRUG CLASS REVIEW

The P&T Committee evaluated the relative clinical effectiveness of the agents in the LIP-1 drug class. This class is currently ranked number one in the MHS with drug class expenditures exceeding $595 million annually. The individual drugs included in the LIP-1 class are listed below:

- *Statins*: atorvastatin (Lipitor), fluvastatin (Lescol), fluvastatin extended release (Lescol XL), lovastatin (Mevacor, generics), lovastatin extended release (Altoprev), pravastatin (Pravachol, generics), rosuvastatin (Crestor), and simvastatin (Zocor, generics)
- *Statin combination products*: atorvastatin/amlodipine (Caduet), lovastatin/niacin extended release (Advicor), and ezetimibe/simvastatin (Vytorin)
- *Add-on therapies:* niacin immediate release (Niacor), niacin extended release (Niaspan), and ezetimibe (Zetia)

The Committee voted (17 for, 0 opposed, 0 abstained, 0 absent) that the following conclusions apply:

1) Across equipotent doses, the statins achieve similar % low density lipoprotein (LDL) lowering, with rosuvastatin 40 mg and ezetimibe/simvastatin 10/80 mg as the only statins capable of achieving LDL lowering >55%.
2) Across equipotent doses, the statins achieve similar % high density lipoprotein (HDL) raising ability, but all statins show a plateau and drop-off of HDL raising effect at increasing doses.
3) There are no head-to-head trials comparing equivalent doses of statins that evaluate clinical outcomes for reducing mortality or other clinical outcomes (e.g., myocardial infarction, stroke, need for revascularization).
4) In low to moderate doses, the effects of atorvastatin, pravastatin and simvastatin appear similar for long-term cardiovascular protection, based on one meta-analysis [Zhou 2006].
5) In trials assessing the primary prevention of coronary heart disease (CHD), beneficial effects on clinical outcomes have been noted with atorvastatin 10 mg, lovastatin 20 to 40 mg, pravastatin 40 mg, and simvastatin 40 mg.
6) In trials assessing the secondary prevention of CHD, beneficial effects on clinical outcomes have been noted with atorvastatin 10 to 80 mg, lovastatin 40 to 80 mg, pravastatin 40 mg, simvastatin 20-40 mg, and fluvastatin 40 mg (administered BID).
7) In one trial assessing acute coronary syndrome patients, beneficial effects on clinical outcomes were noted with atorvastatin 80 mg when it was compared to pravastatin 40 mg [PROVE-IT 2004].
8) There are no published trials assessing the benefits of rosuvastatin on clinical outcomes.
9) There is no evidence that increases in liver function tests or minor adverse events (gastrointestinal disturbances, headaches, rash, itching) are less likely to occur with one statin vs. another, and these adverse effects are dose-related.
10) Concerns of proteinuria and myotoxicity remain with rosuvastatin; the overall incidence of rhabdomyolysis occurs rarely with statins.
11) Fluvastatin, pravastatin, and rosuvastatin have the most favorable drug-drug interaction profiles.
12) There is insufficient evidence to determine whether one statin is less tolerable than another.
13) In terms of other factors, the statins can be initiated at maximum doses, with the exception of rosuvastatin 40 mg.
14) There is insufficient evidence to determine the clinical applicability of differences between the statins in terms of pleiotropic effects or effects on markers of atherosclerotic progression (intravascular ultrasound or carotid intima media thickness).

15) Ezetimibe offers an additional 15-20% LDL lowering by a mechanism distinct from that of the statins, but has not yet been evaluated for clinical outcomes.

16) Ezetimibe/simvastatin provides added efficacy in terms of LDL lowering and has a safety and efficacy profile reflecting that of its two individual components.

17) Niacin extended release is required in the MHS as its primary benefit is to raise HDL by 25%.

18) Lovastatin/niacin extended release, atorvastatin/amlodipine, lovastatin extended release, and fluvastatin extended release do not offer additional clinical benefits over the other LIP- I agents and have low utilization in the MHS (<5,000 Rxs/month dispensed).

19) A survey of MTF providers, including cardiologists, was overwhelmingly in support of simvastatin for treating the 80-85% of MHS patients requiring LDL lowering ≤45%, and also supported use of ezetimibe.

20) Based on clinical issues alone, none of the LIP-1 agents are sufficiently less effective than the others agents within the class to be classified as non-formulary.

Based on the results of the CEA and other clinical and cost considerations, the P&T Committee voted (17 for, 0 opposed, 0 abstained, 0 absent) that (1) simvastatin could meet the vast majority of the needs of patients requiring low to moderate % LDL lowering agents (≤ 45%); (2) ezetimibe/simvastatin was the most cost-effective intensive % LDL lowering agent; (3) some low to moderate % LDL lowering agents were considered to be clinically necessary (pravastatin, ezetimibe, and niacin); (4) of the remaining low to moderate % LDL lowering agents, nothing would be gained clinically or economically by making them non-formulary, especially considering their low market share; (5) atorvastatin/amlodipine was considerably more costly compared to the combination of atorvastatin and a UF dihydropyridine calcium channel blocker, regardless of point of service; and (6) the UF scenario that included the intensive % LDL lowering agents atorvastatin and ezetimibe/simvastatin on the UF was the most cost-effective UF scenario.

A. COMMITTEE ACTION: UF RECOMMENDATION – Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of the LIP-1 agents, and other relevant factors, the P&T Committee, based upon its collective professional judgment, voted (15 for, 1 opposed, 1 abstained, and 0 absent) to recommend that atorvastatin, fluvastatin immediate and extended release, pravastatin, simvastatin, lovastatin immediate and extended release, lovastatin/niacin, ezetimibe/simvastatin, niacin extended & immediate release, and ezetimibe be maintained as formulary on the UF, and that rosuvastatin and the combination product atorvastatin/amlodipine be classified as non-formulary under the UF. (See paragraphs 9A and 9B on pages 28-38 of the P&T Committee minutes.)

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:
"Our efforts to sustain the TRICARE benefit, and the TRICARE Rx benefit, require that MTF prescribers continue using simvastatin when that drug is clinically appropriate. I strongly encourage MTF commanders, doctors and pharmacists to maximize the use of simvastatin."

B. COMMITTEE ACTION: MEDICAL NECESSITY CRITERIA – Based on the clinical evaluation of rosuvastatin and atorvastatin/amlodipine, and the conditions for establishing medical necessity for a non-formulary medication provided in the UF rule, the P&T Committee recommended (15 for, 0 opposed, 1 abstained, 1 absent) medical necessity criteria for the LIP-1 agents. (See paragraph 9C on pages 38-39 of the P&T Committee minutes for criteria

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

C. COMMITTEE ACTION: IMPLEMENTATION PERIOD – The P&T Committee voted (15 for, 0 opposed, 2 abstained, 0 absent) to recommend an effective date no sooner than the first Wednesday following a 90-day implementation period. The implementation period will begin immediately following approval by the Director, TMA. (See paragraph 9D on page 39 of the P&T Committee minutes for rationale.)

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

D. COMMITTEE ACTION: BCF RECOMMENDATION – Based on the relative clinical effectiveness and cost-effectiveness analysis, the P&T Committee voted (15 for, 1 opposed, 1 abstained, 0 absent) to recommend simvastatin, pravastatin, ezetimibe/ simvastatin, and niacin extended release as the BCF selections in this drug class. (See paragraph 9E on page 40 of the P&T Committee minutes.)

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

10. CLASS OVERVIEWS. ATTENTION-DEFICIT / HYPERACTIVITY DISORDER AND NARCOLEPSY MEDICATIONS; SEDATIVE HYPNOTICS I (NON-BENZO-DIAZEPINE SEDATIVE HYPNOTICS); SEDATIVE HYPNOTICS II

Portions of the clinical reviews for each class were presented to the Committee. The Committee provided expert opinion regarding those clinical outcomes considered most important for the PEC to use in completing the clinical effectiveness review, and for developing the appropriate cost effectiveness models. Both the clinical and economic analyses of these three classes will be completed during the November 2006 meeting; no action necessary.

3. REVIEW MINUTES OF LAST MEETING

A. Corrections to the Minutes – May 2006 DoD P&T Committee meeting minutes were approved as written, with no corrections noted.

B. May Minutes Approval – Dr. William Winkenwerder, Jr., M.D., approved the minutes of the May 2006 DoD P&T Committee meeting on July 26, 2006.

4. ITEMS FOR INFORMATION

TRICARE Management Activity (TMA) and DoD PEC staff members briefed the P&T Committee on the following:

A. Beneficiary Advisory Panel (BAP) Briefing – CAPT Buss and CAPT Richerson briefed the members of the DoD P&T Committee regarding the June 29, 2006 BAP meeting. The Committee was briefed on BAP comments regarding the DoD P&T Committee's Uniform Formulary (UF) and implementation recommendations.

B. Administrative Action: Quantity Limits for Tramadol Extended Release (Ultram ER) – Quantity limits apply to all tramadol-containing products, including new formulations, based on DoD P&T Committee recommendations made at the February 2005 meeting and subsequently approved by the Director, TMA, on 18 April 2005. The major potential concern with tramadol is safety (risk of seizure at higher than recommended doses); the potential for overuse or diversion may also exist. The Committee concurred with the specific quantity limits established for a new extended release formulation of tramadol (Ultram ER): 30 tablets per 30 days or 90 tablets per 90 days for all strengths, with quantity limits for the 200- and 300-mg tablets applied collectively. These limits were based on available strengths, dosing, titration, and maximum dose recommendations in product labeling (100-, 200-, and 300-mg extended release tablets initiated at 100 mg once daily and titrated up as necessary by 100-mg increments every five days to a maximum of 300 mg per day). The quantity limit is not collective with the immediate release formulations (tramadol 50 mg tablets and tramadol/acetaminophen 37.5/325 mg tablets) because of differences in strengths, Food and Drug Administration (FDA)-approved indications, and dosing recommendations. The Committee noted that Express Scripts, Inc. (ESI), the contractor for the TRICARE Mail Order Pharmacy (TMOP), and TRICARE Retail Pharmacy Network (TRRx) programs, has established procedures to deal with circumstances that may require temporary overrides of quantity limits (e.g., increases in dose).

C. Administrative Action: Removal of Carbinoxamine/Pseudoephedrine Drops from the Basic Core Formulary (BCF) – Like a number of older products, carbinoxamine combination products have been widely used, but were never approved by the FDA as safe and effective. On 8 June 2006, the FDA announced enforcement actions to stop manufacture of unapproved carbinoxamine-containing products due to safety concerns in children $\leq$ 2 years of age, and as part of ongoing FDA efforts to bring all unapproved products in line with provisions of the Food, Drug, and Cosmetic Act. Manufacturers of unapproved products containing carbinoxamine have been directed to cease manufacture over the next 30 to 90 days. One FDA-approved carbinoxamine 4 mg tablet and one 4 mg/5 mL oral solution will remain on the market, but no combination products. The Committee concurred with an administrative action removing carbinoxamine 1 mg / pseudoephedrine 15 mg per mL oral drops from the BCF. They did not feel that addition of another antihistamine/ decongestant combination to the BCF was warranted at the present time, pending future UF review of these medications.

D. UF Change Request Process – The P&T Committee discussed the process by which MTF healthcare providers could request that the DoD P&T Committee consider potential changes to the BCF, Extended Core Formulary (ECF), or UF, including changes to

medical necessity criteria for non-formulary medications, prior authorization criteria, or quantity limits. The P&T Committee agreed on three general process goals:

1) Requests should contain adequate supporting evidence, including a fair, balanced, and thorough discussion of the relevant clinical literature, and present a rational argument supporting suggested changes.

2) The process should address potential conflicts of interest and discourage pharmaceutical industry representatives from putting pressure on providers to submit requests.

3) The process should require review and concurrence by the local military treatment facility (MTF) P&T Committee.

A request form and supporting materials are currently under development.

E. Fentanyl Patch (Duragesic, generics) – The P&T Committee discussed various issues related to the use of fentanyl patches, including safety warnings from the DoD Patient Safety Center, the FDA, and the Institute of Safe Medication Practices; and the July 2006 Air Force policy on the use of fentanyl patches. Fentanyl, a strong opioid narcotic, can cause severe respiratory depression in patients who are not tolerant to opioids. Other safety issues include failing to remove old patches, unsafe disposal of old patches, application of heat to the patch site (e.g., heating pads, water beds), concurrent use of potent CYP3A4 inhibitors, conditions that affect respiratory function or affect metabolism of fentanyl, abuse, and diversion.

Product labeling for fentanyl patches was strengthened in July 2005 following reports of serious adverse events and fatalities. Fentanyl patches are indicated for management of *persistent*, moderate to severe chronic pain requiring continuous, around-the-clock administration for an extended period of time, that cannot be managed by other means, and ONLY in patients who are already receiving opioids, have demonstrated opioid tolerance, and require a total daily dose at least equivalent to fentanyl 25 mcg/hr. They should not be used for management of acute pain or short periods of opioid analgesia; postop pain, including outpatient/day surgeries; mild pain; or intermittent pain.

F. Implementation Status of UF Decisions – The PEC briefed the members of the Committee on the progress of implementation for drug classes reviewed for UF status since August 2005. The Committee made the following observations:

1) Utilization in all UF classes continues to remain stable, suggesting continued access to drugs within the reviewed classes.

2) Collective utilization of UF agents across all reviewed drug classes and points of service (MTF, TMOP, and TRRx) continues to increase as a percentage of prescriptions dispensed, while utilization of non-formulary agents has decreased. Based on the UF decisions that have been fully implemented since the first UF DoD P&T meeting in February 2005, there has been a 26% reduction in the use of non-formulary agents, including those classes where implementation has only just begun (July 2006).

3) Success in terms of generating increased market share for UF agents (while decreasing market share for non-formulary agents) varies by class and by point of service.

4) Market shares by point of service continue to reflect the degree of utilization management applied to each point of service. The more highly managed points of service (i.e., MTFs) are generating higher market shares of UF agents than the unmanaged points of service (i.e., TMOP and TRRx).

5) For drug classes fully implemented, MTFs have reduced the use of non-formulary drugs by 84% as projected, but the change in the use of non-formulary medications at mail (+1%) and retail (-14%) is significantly less.

6) It appears that more beneficiaries are electing to receive non-formulary medications through TMOP.

5. REVIEW OF RECENTLY-APPROVED AGENTS

The P&T Committee was briefed on five new drugs that were approved by the FDA. None of the medications fall into drug classes already reviewed by the P&T Committee; therefore, UF consideration was deferred until the corresponding drug class reviews are completed.

The P&T Committee reviewed one new drug for quantity limits. Dasatinib (Sprycel) is an oral multi-kinase inhibitor approved for treatment of patients with chronic myeloid leukemia or Philadelphia chromosome-positive acute lymphoblastic leukemia, with resistance or intolerance to prior therapy including imatinib (Gleevec). Dasatinib is available in 20-, 50- and 70-mg tablets which should not be crushed or cut. It is administered at a target dosage of 70 mg twice daily, but dosing can vary from 20 mg once daily to 100 mg twice daily, based on potential drug interactions, patient response, or drug-related adverse effects. Quantity limits were recommended for dasatinib due to the risk of discontinuation of therapy and the probability that dosage adjustments requiring changes in tablet strength will be needed, based on potential drug interactions, patient response to therapy, or drug-related adverse effects. Quantity limits also apply to other oral chemotherapy drugs, including imatinib, erlotinib (Tarceva), sorafenib (Nexavar), and sunitinib (Sutent), based on previous DoD P&T Committee recommendations and subsequent approval by the Director, TMA.

COMMITTEE ACTION – The P&T Committee voted (17 for, 0 opposed, 0 abstained, 0 absent) to recommend quantity limits for dasatinib in TMOP of 90 tablets for the 70 mg strength, 180 tablets for the 50 mg strength, and 180 tablets for the 20 mg strength per 45 days, with a days supply limit of 45 days. In TRRx, the recommended quantity limits were 60 tablets for the 70 mg strength, 120 tablets for the 50 mg strength, and 120 tablets for the 20 mg strength per 30 days, with a days supply limit of 30 days.

6. PRIOR AUTHORIZATION (PA) REQUIREMENT FOR EXENATIDE (BYETTA)

Exenatide is indicated as adjunctive therapy to improve glycemic control in patients with type 2 diabetes mellitus (DM) who are taking metformin, a sulfonylurea, or a combination of metformin and a sulfonylurea, but have not achieved adequate glycemic control. Pharmacologically, exenatide is an incretin mimetic agent that stimulates insulin production in the pancreatic islet cells when glucose levels are elevated, slows gastric emptying, and helps produce a feeling of satiety. Exenatide also reduces the secretion of glucagon, thus lowering elevated post-prandial blood glucose levels. It is given twice daily by subcutaneous injection, prior to the morning and evening meals. Exenatide should not be used as a

substitute for insulin in patients who need insulin, has not been studied in patients also using insulin, and is not indicated for use in patients with type 1 DM.

In clinical trials, exenatide decreased glycosylated hemoglobin A1c (HbA1c) by 0.7 to 1.1% (insulin typically decreases HbA1c by 1-2%). Also noted during clinical trials were reduced sulfonylurea requirements and reductions in weight (1.9 to 4.5 kg). From a safety standpoint, use of exenatide with a sulfonylurea may increase the risk of hypoglycemia, and the sulfonylurea dose may need to be reduced. Concurrent use of exenatide and metformin is relatively unlikely to cause hypoglycemia. Because it slows gastric emptying, exenatide may alter the rate and extent of absorption of oral drugs; drugs dependent on threshold concentrations for efficacy (e.g., antibiotics, contraceptives) should be taken at least one hour prior to exenatide. Exenatide is not recommended in patients with severe gastrointestinal (GI) disease, including gastroparesis, or in patients with severe/end stage renal disease. It is associated with GI adverse effects, including nausea, vomiting, and diarrhea; patients receiving exenatide in clinical trials also complained of significantly more jitteriness, dizziness, and headache than those receiving placebo.

Exenatide has achieved some notoriety as a weight loss medication (even in non-diabetic patients), an off-label use that is both not supported by clinical evidence and not covered by TRICARE. In addition, it appears likely that exenatide may be used in some patients with metabolic syndrome or "pre-diabetes," another off-label use not supported by clinical evidence. Based on results of a utilization study performed by the PEC, about 90% of Military Health System (MHS) patients who received a first prescription for exenatide from June 2005 to May 2006 had also filled a prescription for an oral antidiabetic drugs, blood glucose test strips, or both during the 180 days prior to starting exenatide (8,681 out of a total of 9,634 patients). In other words, about 10% of MHS patients starting exenatide appear unlikely to be diabetic, based on absence of prescription fills for either diabetic medications or blood glucose testing supplies during the six months prior to starting exenatide. While there may be alternative explanations for some of these cases, it appears that some of these patients are receiving exenatide as a weight-loss medication and/or in a setting of "pre-diabetes." Many health plans have PA requirements for exenatide, primarily based on its FDA indication.

The cost of exenatide ranges from $1250 to $2500 per year, depending on dose and pharmacy point of service. Exenatide prescription fills are increasing rapidly at retail network pharmacies, where most exenatide fills are dispensed; relatively few fills and a slower rate of increase are seen at TMOP or MTFs.

Based on the following considerations, the P&T Committee agreed that a PA should be required for exenatide:

- In the MHS, up to 10% of exenatide usage appears likely to be used for indications not covered by TRICARE and/or not supported by clinical evidence. The use of exenatide for weight loss may increase based on continued coverage in the lay press increasing familiarity with the medication. Overall, utilization of exenatide is increasing.
- Modifications to the Pharmacy Data Transaction Service (PDTS) scheduled for completion by December 2006 will add the capability of "looking back" at a given patient's profile for the presence or absence of prescription fills for specific medications within a defined time period. This will allow automation of some PA criteria, reducing

paperwork burden and cost (PA fees), and limiting the scope of the PA to those patients most likely to fail to meet the established criteria.

COMMITTEE ACTION – Based on its potential use for indications not covered by TRICARE and/or not supported by clinical evidence, the P&T Committee recommended that a PA be required for exenatide (14 for, 1 against, 0 abstained, 2 absent). The Committee recommended that the PA should have an effective date no sooner than the first Wednesday following a 30-day implementation period, but as soon thereafter as possible based on availability of the automated PA capability in PDTS. The implementation period will begin immediately following the approval by the Director, TMA.

The Committee agreed that the following PA criteria should apply (14 for, 1 against, 0 abstained, 2 absent). Patients meeting the automated PA criteria would not be required to have their providers submit any additional information and in all likelihood would not even be aware of the existence of the PA. PA approvals would be valid indefinitely.

1) Automated PA criteria:
   - Patient has received any oral antidiabetic agent in the last 120 days
2) PA criteria if automated criteria are not met:
   - Coverage is approved if the patients meets both of the following criteria:
     - Diagnosis of type 2 DM
     - Patient has not achieved adequate glycemic control on metformin, a sulfonylurea, or a combination of metformin and a sulfonylurea

7. THIAZOLIDINEDIONE DRUG CLASS REVIEW

The drugs in the thiazolidinedione (TZD) class include the parent compounds rosiglitazone (Avandia) and pioglitazone (Actos); their respective combinations with metformin, rosiglitazone/metformin (Avandamet) and pioglitazone/metformin (Actoplus Met); and one combination of a TZD with a sulfonylurea, rosiglitazone/glimepiride (Avandaryl). The TZDs accounted for approximately $110 million dollars in Fiscal Year (FY) 2005 and are ranked 12th in MHS drug class expenditures.

A. TZD Relative Clinical Effectiveness

The P&T Committee evaluated the relative clinical effectiveness of the TZD products currently marketed in the United States. Information regarding the safety, effectiveness, and clinical outcomes of these drugs was considered. The clinical review included, but was not limited to, the requirements stated in the UF Rule, 32 CFR 199.21(e)(1). The P&T Committee was advised that there is a statutory presumption that pharmaceutical agents in a therapeutic class are clinically effective and should be included on the UF, unless the P&T Committee finds by a majority vote that a pharmaceutical agent does not have a significant, clinically meaningful therapeutic advantage in terms of safety, effectiveness, or clinical outcome over the other pharmaceutical agents included on the UF in that therapeutic class.

1) Efficacy for Glycemic Control

Rosiglitazone and pioglitazone and their fixed-dose combinations with metformin or

glimepiride are FDA-approved for treating patients with type 2 DM. The primary efficacy measures evaluated included HbA1c and fasting plasma glucose (FPG).

- *Monotherapy* – TZDs may be given as monotherapy, but are usually administered with other antidiabetic drugs, including metformin, sulfonylureas, or insulin. Placebo-controlled trials show that rosiglitazone monotherapy reduces HbA1c by 0.6% to 1.5% and FPG by 33 mg/dL to 55 mg/dL, while pioglitazone monotherapy reduces HbA1c by 0.7% to 1.2% and FPG by 36 mg/dL to 56 mg/dL.
    - *Head-to-Head Monotherapy Trials* – The only rigorously designed head-to-head clinical trial comparing rosiglitazone and pioglitazone monotherapy included 802 patients. The trial showed similar reductions in HbA1c after 24 weeks of therapy (0.6% with rosiglitazone vs. 0.7% with pioglitazone, p=0.129) and FPG (36 mg/dL with rosiglitazone vs. 33 mg/dL with pioglitazone, p=0.233). [Goldberg 2005]
    - *Meta-Analyses* – A meta-analysis of 23 placebo-controlled TZD monotherapy trials concluded that, when relatively equivalent doses of the TZD were compared, similar mean changes from baseline in HbA1c were reported: -0.90% (95% Confidence Interval [CI] -1.42% to -0.38%) with rosiglitazone 4 mg once daily (QD); -0.99% (95% CI -1.32% to -0.66%) with pioglitazone 30 mg QD. Similar point estimates and overlapping confidence intervals were reported for rosiglitazone 8 mg QD and pioglitazone 45 mg QD for reductions in both HbA1c and FPG. [Chiquette 2004]
- *Combination Therapy* – When a TZD is added on to another antidiabetic drug, greater reductions in HbA1c and FPG are seen than if the TZD is administered as monotherapy.
    - *Head-to-Head Combination Therapy Trials* – There is one head-to-head trial comparing the TZDs used in combination with the sulfonylurea glimepiride, which enrolled 91 patients. Similar changes in glycemic parameters from baseline were reported in both treatment groups. HbA1c decreased by 1.3% with rosiglitazone plus glimepiride vs. 1.4% with pioglitazone plus glimepiride; FPG decreased by 31 mg/dL in both groups. [Derosa 2004]
    - *Meta-analyses* – A meta-analysis of 15 clinical trials evaluating metformin, sulfonylurea or insulin plus a TZD compared to metformin, sulfonylurea, or insulin plus placebo concluded that when relatively equivalent doses of the TZDs were compared, similar mean changes from baseline in HbA1c were reported: [-1.05 (95% CI-1.2 to -0.9) with rosiglitazone 4 mg QD plus other antidiabetic drugs vs. -1.16 (95% CI -1.4 to -0.0) with pioglitazone 30 mg QD plus other antidiabetic drugs]. Similar reductions in HbA1c and FPG, with overlapping confidence intervals, were reported for rosiglitazone 8 mg QD plus other antidiabetic drugs vs. pioglitazone 45 mg QD plus other antidiabetic drugs. [Chiquette 2004]
- *Monotherapy and Combination Therapy* – A systematic review evaluating placebo-controlled trials with the TZDs used as either monotherapy or added on to other antidiabetic drugs reported an adjusted indirect comparison between

rosiglitazone and pioglitazone. Overall, there was no significant difference between the two drugs (adjusted mean difference, pioglitazone minus rosiglitazone, of -0.12% (95% CI -0.50 to 0.26)). [State of Oregon 2006]

Conclusion: Efficacy for Glycemic Control – The available evidence suggests that neither rosiglitazone nor pioglitazone is superior to the other in reducing HbA1c or FPG.

2) *Effectiveness for Prevention of Microvascular and Macrovascular Events*

For clinical outcomes, endpoints evaluated included microvascular (e.g., nephropathy, retinopathy, neuropathy) and macrovascular (e.g., cardiovascular disease, cerebral vascular disease, peripheral vascular disease) complications of type 2 DM, when available.

- *Microvascular Complications* – There are no clinical trials with either rosiglitazone or pioglitazone that evaluate the effects of long-term TZD therapy on prevention of microvascular complications. However, both TZDs reduce HbA1c, and reductions in HbA1c are correlated with a reduced risk of microvascular events, as previously shown in the United Kingdom Prospective Diabetes Study.
- *Macrovascular Complications* – Coronary heart disease is the major cause of mortality in diabetic patients, thus clinical trials evaluating cardiovascular outcomes are of importance when comparing the TZDs. There is one published trial, the Prospective Pioglitazone Clinical Trial in Macrovascular Events (PROACTIVE), that evaluated the effects of pioglitazone on clinical outcomes in over 5,000 patients. After three years, there was no significant difference with pioglitazone added to other antidiabetic medications compared to placebo plus other antidiabetic medications in the primary composite outcome, which included both disease and procedure-related endpoints (i.e., myocardial infarction (MI), stroke, need for coronary artery bypass grafting, percutaneous coronary intervention or leg amputation). Overall, 21% of patient reached the primary endpoint with pioglitazone vs. 23% with placebo; p=0.095). However, a significant difference in favor of pioglitazone was reported in a secondary composite endpoint that only included disease-related endpoints (all-cause death, non-fatal MI and stroke); 11.6% with pioglitazone vs. 13.6% with placebo, p=0.027. The design of this trial has been debated, and the clinical applicability of these results is limited. There are no completed trials with rosiglitazone evaluating clinical outcomes, although two trials (ADOPT and RECORD) are underway.

Conclusion: Effectiveness for Prevention of Microvascular and Macrovascular Events – Due to the absence of published trials with rosiglitazone and design limitations of the one published trial with pioglitazone PROACTIVE, there is insufficient evidence to determine whether one TZD is superior to the other in preventing the clinical complications of diabetes.

3) *Safety and Tolerability*

- *Hypoglycemia* – One meta-analysis compared the differences in the incidence of hypoglycemia between rosiglitazone and pioglitazone. The pooled risk

differences were compared with each drug vs. placebo, and the results were similar for each TZD; rosiglitazone risk difference vs. placebo 3% (95% CI 0% to 5%) and pioglitazone risk difference vs. placebo 2% (95% CI -1% to 4). [State of Oregon 2006]

- *Edema* – Mild to moderate edema has been reported with the TZDs and appears to be dose-related. One meta-analysis reported the pooled risk difference for the incidence of edema with the TZDs in placebo-controlled trials. The pooled risk difference compared to placebo was similar between the two TZDs: rosiglitazone 4% (95% CI 2% to 5%), pioglitazone 4% (95% CI 2% to 7%). [State of Oregon 2006]
- *Heart Failure* – Both rosiglitazone and pioglitazone have been linked to development of heart failure; neither are recommended for use in patients with New York Heart Association Class III or IV heart failure Product labeling for both rosiglitazone and pioglitazone are similar regarding warnings for fluid retention, which may lead to or worsen heart failure. The highest risk occurs when a TZD is used in combination with insulin. A retrospective review using a large health plan database found no difference between the two TZDs in the development of heart failure in a cohort of over 28,000 patients: rosiglitazone 2.39% vs. pioglitazone 1.63%; p=0.091. [Delea 2003]
- *Weight Gain* – Both TZDs cause statistically significant increases in body weight from baseline. The effect on body weight appears similar between TZDs, as evidenced by the results from head-to-head clinical trials – mean weight gain of 1.6 kg with rosiglitazone vs. 2.0 kg with pioglitazone – and published meta-analyses showing similar weight gain (about 3 kg with each TZD, with overlapping confidence intervals).
- *Hepatotoxicity* – Clinical trials for both TZDs report an incidence <1% for elevations in ALT three times the upper limit of normal. Both TZDs carry similar labeling regarding monitoring of liver enzymes.
- *Blood Pressure* – An association between TZD use and small but statistically significant reductions in blood pressure has been reported. There is insufficient information at this time to determine whether the blood pressure effects are different between rosiglitazone and pioglitazone.
- *Hematologic Effects* – Reductions in hemoglobin and hematocrit have been reported with both TZDs. This may be due to an increase in plasma volume rather than a decrease in red cell mass. The clinical significance of these hematologic effects is unknown.
- *Macular Edema* – An association between TZD use and macular edema has been reported in the literature. GlaxoSmithKline issued a “Dear Doctor Letter” on January 5, 2006 regarding the association of rosiglitazone with new onset and worsening macular edema. Takeda, the manufacturer of pioglitazone, disputes the occurrence of this adverse effect and has not issued a similar warning.
- *Drug-Drug Interactions* – The potential for drug-drug interactions may be greater with pioglitazone than rosiglitazone, due to metabolism of the former by CYP3A4

enzymes. However, the clinical significance of the drug-drug interactions with pioglitazone may be counterbalanced by the availability of multiple metabolic pathways. Of note, use of pioglitazone with oral contraceptives containing ethinyl estradiol and norethindrone has resulted in reduced plasma concentrations of both hormones by 30%, which could result in decreased contraceptive efficacy. The clinical significance of this interaction is unknown, and no dosage adjustments are required in the package labeling for pioglitazone.

- *Withdrawal Due to Adverse Effects* – Drug discontinuations due to adverse effects were similar for rosiglitazone and pioglitazone in one head-to-head monotherapy trial: 2.7% for both TZDs [Goldberg 2005]. A systematic review reported withdrawal rates due to adverse effects of 4.9% with rosiglitazone vs. 4.8% with pioglitazone. [State of Oregon 2006]

Conclusion: Safety and Tolerability – The risk of heart failure, hypoglycemia, weight gain and edema do not appear to differ between rosiglitazone and pioglitazone. Hepatotoxicity has not been a concern with either TZD. There is insufficient evidence to determine whether the TZDs differ in respect to macular edema, changes in blood pressure, hemoglobin or hematocrit; only small changes from baseline in these parameters have been noted. The potential for drug-drug interactions may be greater with pioglitazone than rosiglitazone, but this does not appear to have translated into a clinically significant difference between the two TZDs. The tolerability profiles of both TZDs appear similar, based on drug withdrawals due to adverse effects during clinical trials.

4) Effects on Lipid Parameters

The TZDs exhibit other actions that can have unintended consequences in type 2 DM patients. Treatment with rosiglitazone and pioglitazone can affect serum lipid parameters, including total cholesterol (TC), high-density lipoprotein (HDL) cholesterol, low-density lipoprotein (LDL) cholesterol, and triglycerides (TG). Diabetes is a coronary heart disease (CHD) risk equivalent, and most type 2 DM patients require treatment with lipid lowering therapy. CHD is the number one cause of death in type 2 DM patients.

- Two head-to-head trials (one as monotherapy, the other as add-on therapy with other diabetic medications) reported that rosiglitazone adversely affected the lipid panel, as reflected by increases in TC (by 15-16%), LDL (by 17-23%), and TG (by 15-18%). In contrast, pioglitazone showed a favorable effect on the lipid profile, as reflected by to increases in HDL (by 15%), and decreases in TG (by 12 to 22%). However, these two head-to-head trials differed in the reported results for the effect of pioglitazone on TC and LDL. Goldberg et al (2005) showed an increase in TC (6%) and LDL (16%), while Derosa et al (2003) showed a reduction in TC (by 6%) and LDL (by 12%).
- Two meta-analyses [Chiqeutte 2004 and Canada 2002] concluded that rosiglitazone therapy resulted in increases in TC (10-21%), LDL (7-15%), and HDL (2-3%), but did not affect TGs. Pioglitazone increased HDL (2-5%) and reduced LDL (0.4 to 0.5%). Reductions in TG were more pronounced with pioglitazone, but a statistically significant difference was noted only for

pioglitazone in the Canadian analysis. Both TZDs were associated with modest increases in HDL (by 2-5%); the marked difference between rosiglitazone and pioglitazone seen in the two head-to-head trials is not as noticeable in the two meta-analyses.

Conclusion: Effects on Lipid Parameters – Results from two head-to-head clinical trials and two meta-analyses that assessed the lipid effects with TZDs vary, but are mostly consistent with the results of the head-to-head monotherapy trial. [Goldberg 2005] Pioglitazone appears to have a more favorable effect on lipid parameters than rosiglitazone. The clinical significance of this difference has yet to be determined.

5) *Other Factors*

- Rosiglitazone is dosed either once or twice daily, while pioglitazone is dosed once daily.
- Rosiglitazone binds primarily to peroxisome proliferator-activated receptors (PPARs) gamma receptors, while pioglitazone binds to both PPAR gamma and alpha receptors; differences in receptor binding are theorized to account for differences in the effects on lipid parameters.
- There are no differences in the product labeling for the two TZDs for FDA-approved indications, contraindications, and use in special populations.
- Neither rosiglitazone nor pioglitazone are indicated for use in the pediatric population, in pregnancy, or while breast feeding.
- A survey of MTF providers revealed a split opinion as to whether the TZDs were therapeutically interchangeable, with half of the respondents favoring pioglitazone due to once-daily dosing and lack of detrimental effect on lipids, and the other half voicing no preference.

Conclusion: Other factors – There are only minor differences in terms of other factors for the TZDs. MTF provider opinion is split between preferring pioglitazone and no preference between the two.

Overall Clinical Effectiveness Conclusion – The Committee concluded that:

1) Neither rosiglitazone nor pioglitazone appears less effective in reducing elevated hemoglobin A1c or fasting plasma glucose values.
2) There is insufficient evidence to determine if there are significant differences between the two parent compounds in the prevention of microvascular or macrovascular complications of diabetes.
3) Neither rosiglitazone nor pioglitazone appears less likely to cause hepatotoxicity, congestive heart failure, weight gain, edema, decreased blood pressure, hypoglycemia, or reduced hemoglobin and hematocrit.
4) Safety and tolerability differences appear to be limited to a possibly greater potential for drug interactions with pioglitazone.
5) Rosiglitazone appears to have a less favorable effect on lipid parameters than pioglitazone, however the clinical significance of this is unknown.

6) There are only minor differences between the two TZDs based on dosing frequency and receptor binding; provider opinion was split between preferring pioglitazone and no preference.

7) Neither rosiglitazone nor pioglitazone – or their respective combination products – appears sufficiently less clinically effective than the other to warrant classification as non-formulary under the UF based on clinical issues alone.

COMMITTEE ACTION – The P&T Committee voted (16 for, 0 opposed, 1 abstained, 0 absent) to accept the clinical effectiveness conclusions stated above.

B. TZD Relative Cost Effectiveness

The P&T Committee evaluated the relative cost-effectiveness of the TZDs in relation to efficacy, safety, tolerability, and clinical outcomes of the other agents in the class. Information considered by the P&T Committee included, but was not limited to, sources of information listed in 32 CFR 199.21(e)(2).

Given the evidence-based relative clinical effectiveness evaluation conclusion that there was insufficient evidence to suggest that the TZDs differed in regards to efficacy, safety, tolerability, or clinical outcomes in the treatment of type 2 DM, two cost-minimization analyses (CMAs) were performed to determine the relative cost-effectiveness of the agents within the TZD class.

1) The first CMA evaluated the agents based on their total weighted average cost per day of treatment, which was derived from their submitted prices for UF condition sets (1 of 1 TZD agent on the UF or 1 of 2 TZD agents on the UF) and their utilization history. The results of this analysis revealed that pioglitazone was more cost-effective compared to rosiglitazone for a 1 of 1 position on the UF, whereas rosiglitazone was more cost-effective compared to pioglitazone for a 1 of 2 position on the UF.

2) The second CMA evaluated the agents under various UF scenarios which placed one or more agents on the UF. In this analysis, all viable UF scenarios were considered. The various UF scenarios were evaluated on their projected post-decision total weighted average cost per day of treatment. The results of this analysis showed that the UF scenario that included both agents on the UF to be the most cost-effective.

To account for other factors and costs associated with a UF decision (market share migration, switch costs, non-formulary cost shares, and medical necessity processing fees), a budget impact analysis was performed. The goal of the budget impact analysis (BIA) was to assist the Committee in determining which group of TZDs best met the majority of the clinical needs of the DoD population at the lowest cost to the MHS.

Cost Effectiveness Conclusion – Based on the BIA results and other clinical and cost considerations, the Committee agreed that the UF scenario that included both of the TZD agents and their associated combination products on the UF best achieved this goal when compared to other more restrictive alternative UF scenarios, and thus was determined to be more cost-effective relative to other UF scenarios. The P&T Committee, based upon its collective professional judgment, voted (16 for, 0 opposed, 1 abstention, 0 absent) to accept the TZD cost analysis presented by the PEC. The P&T Committee concluded that the UF scenario that maintained rosiglitazone, pioglitazone, rosiglitazone/metformin,

pioglitazone/metformin, and rosiglitazone/glimepiride on the UF was the most cost effective UF scenario considered.

COMMITTEE ACTION – Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of the TZD agents, and other relevant factors, the P&T Committee, based upon its collective professional judgment, voted (13 for, 1 opposed, 1 abstention, 1 absent) to recommend that rosiglitazone, pioglitazone, rosiglitazone/metformin, pioglitazone/metformin, and rosiglitazone/glimepiride be maintained as formulary on the UF and that no agents from this class be classified as non-formulary under the UF.

C. TZD Medical Necessity Criteria – Since no agents were recommended for non-formulary status under the UF, establishment of medical necessity criteria is not applicable.

D. TZD UF Implementation Period – Since no agents were recommended for non-formulary status under the UF, establishment of an implementation plan is not applicable.

E. TZD Basic Core Formulary (BCF) Review and Recommendations – The P&T Committee had previously determined that no more than one parent TZD, with or without its associated combinations, should be added to the BCF based on the clinical and cost effectiveness review. As a result of the clinical and economic evaluations presented, the P&T Committee recommended that rosiglitazone and rosiglitazone/metformin be maintained on the BCF. The Committee did not recommend addition of rosiglitazone/glimepiride to the BCF.

COMMITTEE ACTION – The P&T Committee voted (13 for, 1 opposed, 3 abstention, 0 absent) to recommend retaining rosiglitazone and rosiglitazone/metformin as the BCF selections in this class. The Committee did not recommend addition of rosiglitazone/ glimepiride to the BCF.

8. HISTAMINE-2 (H2) ANTAGONISTS AND OTHER GASTROINTESTINAL (GI) PROTECTANTS

This drug class is comprised of the four H2 receptor antagonists (H2 antagonists), ranitidine (Zantac, generics), cimetidine (Tagamet, generics), famotidine (Pepcid, generics), and nizatidine (Axid, generics); the prostaglandin analog misoprostol (Cytotec, generics); and the mucosal protectant sucralfate (Carafate, generics). These six drugs have been marketed for several years, and all are available in generic formulations. This drug class accounted for $10.9 million dollars in FY 2005, and is ranked approximately 75th in MHS drug class expenditures. More than 440,000 prescriptions for these medications are filled annually in the MHS, based on prescription data from July 2005 to June 2006.

A. H2 Antagonists & Other GI Protectants Relative Clinical Effectiveness

The P&T Committee evaluated the relative clinical effectiveness of the H2 antagonists and other GI protectant agents. The clinical review included, but was not limited to, the requirements stated in the UF Rule, 32 CFR, 199.21 (e)(1).

1) Efficacy

- *H2 Antagonists and GI Indications* – All four of the H2 antagonists have been

shown in numerous clinical trials to reduce gastric acid pH, particularly after a meal. They are all effective when used before meals to reduce reflux symptoms associated with food or exercise. Although largely replaced by proton pump inhibitors (PPIs) in clinical practice, H2 antagonists may still play a role in the treatment of gastroesophageal reflux disease (GERD), peptic ulcer disease, and *H. pylori* infections. A 1997 drug class review conducted by the Department of Veterans Affairs, as well as the 1999 American College of Gastroenterology guidelines for the treatment of GERD, concluded that, although there are differences in the potency, duration of action and onset of action, H2 antagonists may be used interchangeably at equivalent doses. A search of the literature since 1999 yields little additional clinical literature concerning the H2 antagonists and does not change this conclusion.

- *H2 Antagonists and Non-GI Indications* – Cimetidine is distinct from the other H2 antagonists in that it has evidence to support use in non-GI conditions based both on its histamine-blocking characteristics and its apparent immunomodulating effects. Non-GI uses for cimetidine are numerous, and include treatment of chronic idiopathic urticaria, adjunctive treatment of cancer or herpes virus infections, and intermittent porphyria.
- *Sucralfate* – Sucralfate does not affect gastric acid pH, but is thought to act by forming a non-absorbable physical barrier over mucosal ulcerations. At least ten clinical trials addressing the treatment of both gastric and duodenal ulcers (all conducted in the 1980s) reported similar healing rates with sucralfate compared to cimetidine or ranitidine. Overall, sucralfate appears to be as effective and safe as the H2 antagonists for treating duodenal and gastric peptic ulcers, but it is only approved for treating duodenal ulcers. One landmark clinical trial comparing intravenous (IV) ranitidine with nasogastric sucralfate reported benefits for use in stress ulcer prophylaxis in the intensive care setting, where it may offer an advantage over IV use of the H2 antagonists, due to a reduced potential for development of aspiration pneumonia. Sucralfate should be reserved for mild cases of esophagitis only. As with the H2 antagonists, the popularity of sucralfate has diminished due to availability of PPIs.
- *Misoprostol* – Misoprostol is a synthetic prostaglandin analog that inhibits gastric acid secretion by directly stimulating parietal cells. It also appears to function as a mucosal protective agent. The drug is effective as an adjunctive medication to reduce GI events associated with non-steroidal anti-inflammatory drug (NSAID) use, and has been shown to significantly reduce the risk of NSAID-associated serious GI complications and symptomatic ulcers by about 40-60%. Non-GI (off-label) uses of misoprostol are primarily gynecological in nature. A review of MHS utilization patterns, based on quantities dispensed and the age and gender of patients receiving misoprostol, confirms that the overwhelming majority of misoprostol usage in DoD is for treatment of GI conditions.

2) Safety and Tolerability

- *H2 Antagonists* – There are no major differences between the four H2 antagonists with respect to safety and tolerability, with the exception of a greater potential for

drug interactions with cimetidine. Cimetidine inhibits cytochrome P450 enzymes, and is associated with several clinically significant drug interactions when administered concomitantly with other drugs metabolized via the CYP450 pathway, including theophylline, phenytoin, quinidine, nifedipine, amitriptyline, and warfarin. Labeling for all four H2 antagonists contains warnings concerning an association of H2 antagonist use with necrotizing enterocolitis in the fetus or neonate. All four are associated with minor complaints of nausea, vomiting, diarrhea or constipation.

- *Sucralfate* – The major safety concern with sucralfate is the risk of seizures due to aluminum absorption in patients with impaired renal function. There are reports of bezoar development in patients with gastroparesis. Constipation develops in about 3% of patients receiving sucralfate, and complaints of metallic taste and diarrhea are frequent. The aluminum component of sucralfate may interact with antacids.
- *Misoprostol* – A Cochrane review addressing adverse events found that significantly more patients receiving misoprostol vs. placebo withdrew from therapy due to adverse effects, primarily diarrhea, abdominal pain, and nausea [Rostom 2004]. Diarrhea occurs in 13% to 40% of patients. It is dose-related, occurs early in treatment, usually resolves with continued treatment, and can be minimized with administration with meals and at bedtime and avoidance of magnesium-containing antacids. Abdominal pain is reported in 7% to 20% of patients. Misoprostol is rated pregnancy category X, and is contraindicated in women of child-bearing age unless the benefits exceed the risks.

3) Other Factors

- *Dosing* – The four H2 antagonists exhibit minor differences in potency, duration of action, onset of action, and frequency of dosing. Cimetidine requires twice daily to four times daily dosing, while the remaining three H2 antagonists can be dosed once to twice daily.
- *Available formulations* – All four H2 antagonists are available in tablet and liquid dosage formulations. The available dosage formulations for sucralfate include a tablet and oral suspension, while misoprostol is only available in a tablet. Ranitidine is also available in a gel-filled capsule, granule, and effervescent tablet.
- *Utilization* – Of the six drugs included in the class, the H2 antagonists account for over 90% of the prescriptions written in the MHS for this drug class. Ranitidine is the most widely prescribed H2 antagonist in the MHS, accounting for 67% of all H2 antagonist prescriptions, followed by famotidine (22%), cimetidine (8%) and nizatidine (3%).
- *Pediatrics* – Ranitidine and famotidine are indicated for use in children as young as two years of age; nizatidine is indicated in children older than 11 years, and cimetidine is indicated for use in children older than 15 years of age.
- *Pregnancy* – The four H2 antagonists and sucralfate are rated as pregnancy category B. Misoprostol is rated as pregnancy category X.

Overall Clinical Effectiveness Conclusion - The Committee concluded that:

1) The four H2 antagonists ranitidine, cimetidine, famotidine, and nizatidine are widely considered interchangeable for treatment of GERD, peptic ulcer disease and *H. pylori* infections, despite differences in potency, duration of action, and onset of action.
2) Compared to the other three H2 antagonists, cimetidine has evidence for use in non-gastrointestinal conditions.
3) Ranitidine is the most widely used H2 antagonist across the MHS, is dosed once or twice daily, has a low potential for drug interactions, and is available in an oral syrup for pediatric patients.
4) Famotidine and nizatidine have similar dosing intervals, drug interaction profiles and formulations as ranitidine, but are less frequently prescribed in the MHS.
5) Cimetidine is more difficult to use clinically compared to the other three H2 antagonists due to its need for multiple daily dosing (BID-QID) and drug interaction profile.
6) Misoprostol serves a unique niche for use in high risk patients for NSAID-induced ulcers, despite its adverse effect profile and warnings in women of child bearing age.
7) Sucralfate has a unique mechanism of action (physical barrier formation) and offers an alternative to PPIs and H2 antagonists for stress ulcer prophylaxis.

COMMITTEE ACTION – The P&T Committee voted (16 for, 0 opposed, 0 abstained, 0 absent) to accept the clinical effectiveness conclusions stated above.

B. H2 Antagonists & Other GI Protectants Relative Cost Effectiveness

In considering the relative cost-effectiveness of pharmaceutical agents in this class, the P&T Committee evaluated the costs of the agents in relation to the safety, effectiveness, and clinical outcomes of the other agents in the class. Information considered by the P&T Committee included but was not limited to sources of information listed in 32 CFR 199.21(e)(2).

A simple cost analysis was employed to assess the relative cost-effectiveness of the agents within the H2 antagonist/GI protective therapeutic class. The agents within this class were evaluated on their weighted average cost per unit. The results of the cost analysis showed ranitidine to be the most cost effective H2 antagonist. A sole source joint DoD/VA contract is currently in place for ranitidine. The other generic H2 antagonists were shown to have similar relative cost-effectiveness compared to ranitidine, with the exception of nizatidine. Not surprisingly, nizatidine was found to be slightly more costly compared to the other generic H2 antagonists, since a generic version has only recently become available. In regards to misoprostol and sucralfate, both of these agents are available in generic versions and have a niche place in therapy for select patients.

Conclusion – The P&T Committee, based upon its collective professional judgment, voted (16 for, 0 opposed, 1 abstention, 0 absent) to accept the H2 antagonists and other

GI protectants cost analysis presented by the PEC. The P&T Committee concluded that the H2 antagonists ranitidine, cimetidine, famotidine and nizatidine; the prostaglandin analog misoprostol; and the mucosal protective agent sucralfate should be maintained on the UF.

COMMITTEE ACTION – Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of the H2 antagonists and other GI protectants, and other relevant factors, the P&T Committee, based upon its collective professional judgment, voted (17 for, 0 opposed, 0 abstained, 0 absent) to recommend that the H2 antagonists ranitidine, cimetidine, famotidine and nizatidine; the prostaglandin analog misoprostol; and the mucosal protective agent sucralfate should be maintained on the UF and that no agents from this class be classified as non-formulary under the UF.

C. H2 Antagonists & Other GI Protectants Medical Necessity Criteria – Since no agents were recommended for non-formulary status under the UF, establishment of medical necessity criteria is not applicable.

D. H2 Antagonists & Other GI Protectants UF Implementation Period – Since no agents were recommended for non-formulary status under the UF, establishment of an implementation plan is not applicable.

E. H2 Antagonists & Other GI Protectants BCF Review and Recommendations – The P&T Committee had previously determined that one or more agents in this class should be considered for addition to the BCF. Currently, ranitidine (Zantac, generics) is on the BCF, with the effervescent tablet and gel-filled capsule formulations specifically excluded. The committee agreed that ranitidine should remain on the BCF. Since the gel-filled capsule and effervescent tablet dosage formulations were shown to be 19 to 64 times more costly per unit than generic ranitidine without offering any substantial increase in clinical effectiveness, the P&T Committee agreed that the gel-filled capsule and effervescent tablet formulations should continue to be excluded from the BCF.

COMMITTEE ACTION – The P&T Committee voted (17 for, 0 opposed, 0 abstained, 0 absent) to recommend retaining ranitidine as the BCF selection in this class, excluding the effervescent tablet and gel-filled capsule formulations.

9. ANTILIPIDEMIC AGENTS 1 DRUG CLASS REVIEW

The P&T Committee evaluated the relative clinical effectiveness of the Antilipidemic Agents I (LIP-1) agents. This class is currently ranked number one in the MHS with drug class expenditures exceeding $595 million annually. On average, during a twelve month period from July 2005 and ending June 2006, there were approximately 975,000 unique utilizers per quarter. Individual drugs in the LIP-1 class are listed below:

- *Statins*. atorvastatin (Lipitor), fluvastatin (Lescol), fluvastatin extended release (Lescol XL), lovastatin (Mevacor, generics), lovastatin extended release(Altoprev), pravastatin (Pravachol, generics), rosuvastatin (Crestor, generics), and simvastatin (Zocor, generics)
- *Statin combination products*. atorvastatin/amlodipine (Caduet), lovastatin/niacin extended release (Advicor), and ezetimibe/simvastatin (Vytorin)

- *Add-on therapies:* niacin immediate release (Niacor), niacin extended release (Niaspan), and ezetimibe (Zetia)

A. LIP-1 Relative Clinical Effectiveness Review:

Information regarding the safety, effectiveness, and clinical outcomes of the LIP-1 agents was considered. The Committee's review focused primarily on the agents' ability to lower LDL concentrations, to raise HDL concentrations, and to reduce clinical outcomes including all-cause mortality, cardiovascular mortality, myocardial infarction (MI), stroke, and need for revascularization. Differences in the agents' effect on triglyceride concentrations, and benefits in treating non-cardiovascular conditions were not assessed in detail. The clinical review included, but was not limited to, the requirements stated in the UF Rule, 32 CFR 199.21(e)(1).

1) Efficacy for %LDL lowering and %HDL raising

Endpoints: The differences between the statins in terms of %LDL lowering and %HDL raising were assessed. Elevated LDL concentrations and low HDL concentrations are both strong independent risk factors of CHD.

%LDL Lowering:

- The primary action of the statins is to reduce elevated LDL concentrations, which is the main target of cholesterol-lowering therapy recommended by the National Cholesterol Education Program Adult Treatment Panel III (NCEP ATP III) guidelines. LDL reduction occurs in a dose-dependant fashion with the statins. However, increasing a statin dose provides only an additional 5 to 6% LDL lowering.
- Data obtained from the individual statin product labeling and clinical trials was used to compare differences in the agents' ability to lower LDL. The statins were divided into two groups: the low to moderate group can achieve ≤45% LDL lowering, and the intensive group can achieve >45% LDL lowering. (See Appendix E)
- The following statins are considered low to moderate %LDL lowering statins: all doses of fluvastatin, fluvastatin extended release, pravastatin, lovastatin, lovastatin extended release, atorvastatin 10 and 20 mg (as well as corresponding Caduet doses which include atorvastatin 10 or 20 mg), simvastatin 10, 20, and 40 mg, ezetimibe/simvastatin 10/10 mg, and rosuvastatin 5 mg.
- The following statins are considered intensive %LDL lowering statins: atorvastatin 40 and 80mg (as well as corresponding Caduet doses which include atorvastatin 40 and 80 mg), rosuvastatin 10, 20, and 40 mg, simvastatin 80 mg, and ezetimibe/simvastatin 10/20, 10/40, and 10/80 mg.
- When equipotent doses are used, the statins achieve similar %LDL lowering (e.g., atorvastatin 20 mg, simvastatin 40 mg and ezetimibe/simvastatin 10/10 mg all attain 41 to 45% LDL lowering). Rosuvastatin 40 mg and ezetimibe/simvastatin 10/80 mg are the only statins capable of attaining >55% LDL lowering.
- Based on a previous model constructed by the PEC that evaluated National Health and Nutrition Examination Survey data, 80 to 85% of the DoD population

requiring a statin is expected to attain their LDL goal on simvastatin doses ≤40mg. Simvastatin is the highest utilized statin in the DoD. (See Figure 1).

%HDL Raising:

- The primary clinical use of the statins is to reduce elevated LDL concentrations; however beneficial effects on HDL are also seen.
- Evidence from published trials and product labeling support the conclusion that HDL generally rises in a dose-dependent fashion, however all statins show a plateau and drop-off of HDL raising effect as the highest doses are approached. For example, atorvastatin 20 mg, simvastatin 40 mg and ezetimibe/simvastatin 10/10 mg can achieve an 8 to 9% increase in HDL concentrations, but at doses of atorvastatin 80 mg and ezetimibe/simvastatin 10/40 mg, only achieve a 5-6% increase in HDL.
- The Committee commented that other drugs that primarily target HDL are available (e.g., niacin, fibrates, bile acid resins), and that providers should choose a drug other than a statin if the primary goal is to raise HDL concentrations. Currently the most potent option for raising HDL is niacin.

2) *Efficacy for clinical outcomes:*

Endpoints: The main clinical endpoints used to evaluate differences in statin efficacy include all-cause mortality, cardiovascular mortality, MI, stroke, and need for revascularization. Numerous clinical trials have shown the benefits of statin therapy on reducing cardiovascular events. However, differences in clinical outcomes between the statins are difficult to compare, due to widely varying patient populations evaluated, vaguely defined endpoints, and comparison of non-equipotent statin doses.

Meta-analyses:

- There are no head-to-head trials comparing equivalent doses of statins that evaluate differences in mortality or other clinical outcomes. One meta-analysis (Zhou 2006) evaluated the differences between low to moderate doses of atorvastatin, simvastatin, and pravastatin in reducing mortality or cardiovascular events. Eight clinical trials (comprising both primary and secondary prevention trials) met the criteria for inclusion in the analysis. An adjusted indirect comparison was calculated.
- For all comparisons between the three statins (e.g., atorvastatin vs. pravastatin, atorvastatin vs. simvastatin, and simvastatin vs. pravastatin), there was no significant difference between the drugs in all-cause mortality, major coronary events (fatal CHD and nonfatal MI), cardiovascular death (coronary and cerebrovascular death), and major cardiovascular events (stroke); ($p>0.05$ for all comparisons).

Efficacy for primary prevention of CHD: Primary prevention trials consist of patients without clinically evident CHD. Beneficial effects on clinical outcomes for primary prevention of CHD have been noted with atorvastatin 10 mg (ASCOT-LLA and CARDS trials), lovastatin 20 to 40 mg (AFCAPS, TexCAPS trials), pravastatin 40 mg (WOSCOPS), and simvastatin 40 mg (HPS).

Efficacy for secondary prevention of CHD: Secondary prevention trials include patients with pre-existing cardiovascular disease, such as prior MI, or prior revascularization procedures. In trials assessing the secondary prevention of coronary heart disease (CHD), beneficial effects on clinical outcomes have been noted with atorvastatin 10 to 80 mg (GREACE, TNT), lovastatin 40 to 80 mg (CABG), pravastatin 40 mg (LIPID, CARE), simvastatin 20 to 40 mg (4S), and fluvastatin 40 mg (administered bid) (LIPS).

- TNT: In the Treat to Target (TNT) trial, low dose atorvastatin 10 mg was compared to intensive dose atorvastatin 80 mg for 5 years in 10,000 patients with stable CHD. Intensive dose atorvastatin 80 mg was associated with significantly fewer patients reaching the primary composite outcome (which included non-fatal MI) vs. atorvastatin 10 mg (28.1% vs. 33.5%, $p<0.001$). There was no benefit of intensive dose atorvastatin when mortality was assessed as a single endpoint. The main conclusion was that reducing LDL to <100 mg/dL yielded incremental clinical benefits.
- IDEAL: In the Incremental Decrease in End Points through Aggressive Lipid Lowering (IDEAL) trial, intensive dose atorvastatin 80 mg was compared to low to moderate dose simvastatin 20 to 40 mg. In contrast to TNT, intensive dose atorvastatin did not show a benefit in the primary composite endpoint (CHD death, hospitalized non-fatal MI, resuscitated cardiac arrest); (9.3% of atorvastatin patients reached the primary endpoint, vs. 10.4% of simvastatin patients; $p=0.07$).

Efficacy for ACS: A subgroup of secondary prevention trials focuses on ACS patients who can experience unstable angina and myocardial ischemia due to severe atherosclerotic plaque progression.

- PROVE-IT:
  - In the Pravastatin or Atorvastatin Evaluation and Intensive Therapy (PROVE-IT) trial, moderate dose pravastatin 40 mg was compared to intensive dose atorvastatin 80 mg for two years in over 4,000 recently hospitalized (< 10 days) patients with ACS. Significantly fewer patients receiving intensive dose atorvastatin 80 mg reached the primary composite endpoint (all cause death, MI, unstable angina requiring hospitalization, stroke) than moderate dose pravastatin 40 mg (22.4% vs. 26.3%, $p=0.005$).
  - The PROVE-IT trial provides evidence for immediate use of intensive dose statin in ACS patients. Additionally, a goal LDL <70 mg/dL should be considered in this population, as the ending mean atorvastatin LDL was 62 mg/dL vs. 95 mg/dL with pravastatin 40 mg.
  - It is unknown whether the beneficial results seen in the PROVE-IT trial would be duplicated if an intensive dose statin other than atorvastatin were evaluated, as no such studies have been published.
- PACT: In the Pravastatin in Acute Treatment (PACT) trial, pravastatin 20 to 40 mg did not show a reduction in coronary events vs. placebo, however statin administration was delayed for 24 hours and the trial duration was only 4 weeks.

- A to Z: In the Aggrastat to Zocor (A to Z) trial, no statistically significant reduction in coronary events was shown after 2 years in 4,000 ACS patients receiving early initiation (after one month) intensive dose simvastatin 40 to 80 mg vs. delayed initiation (after four months) of low dose simvastatin 20 mg. The long delay in statin administration, and not the individual statin evaluated, likely contributed to the negative results.

Rosuvastatin and ezetimibe/simvastatin: There are no published trials assessing the benefits of rosuvastatin on clinical outcomes; one large trial (JUPITER) is in progress. While there are no clinical trials specifically assessing the ezetimibe/ simvastatin formulation, there is evidence for clinical benefits of the simvastatin component from the Scandinavian Simvastatin Survival Study (4S) and Heart Protection Study (HPS) trials. There is no evidence to suggest that addition of ezetimibe to simvastatin would negate the clinical benefits of the simvastatin component.

3) *Safety and Tolerability*

Minor Adverse Events: The statins show similar common adverse event profiles. Data from the package insert suggests that the there is no evidence that minor adverse events (GI disturbances, headaches, rash, itching) are less likely to occur with one statin vs. another. These adverse effects appear dose-related.

Serious Adverse Events: The P&T Committee specifically focused on three main areas, elevated liver transaminases, proteinuria, and myotoxicity.

- Elevations in liver transaminases
  - Transient elevations of aspartate aminotransferase and alanine amino-transferase (AST/ALT) to greater than three times the upper limit of normal (ULN) can occur with all the statins. The incidence of elevations in transaminases with all the statins ranges from 0.3 to 3%, according to data from statin package inserts.
  - Increases in liver transaminases are more likely to occur with intensive dose statins vs. low to moderate dose statins. No evidence suggests that one statin is less likely than another to cause increased liver transaminases. There is no data to date that suggest elevations in ALT or AST are predictive of liver injury or long term hepatotoxicity.
- Proteinuria:
  - A retrospective analysis conducted by the FDA using preclinical NDA submissions reported that rosuvastatin 40 mg was associated with a 4 to 5% incidence of proteinuria. This was higher than the incidence reported with rosuvastatin doses $\leq$20 mg (1 to 4%), atorvastatin 10 to 80 mg (0.4% to 2%), simvastatin 20 to 80 mg (0.6% to 4%), or pravastatin 20 to 40 mg (0 to 1%). Limitations to this analysis include the use of spot urine dipstick testing rather than 24-hour urine collections, and the inclusion of data from both open label and placebo-controlled trials.

- Currently there are no requirements for monitoring of renal function with any of the statins. Due to the insufficient and poor quality evidence available at this time, it cannot be determined whether the incidence of proteinuria differs between the statins.

- Myotoxicity:
  - Varying definitions of the terms myotoxicity, myopathy, myalgia, myositis, and rhabdomyolysis make interpretation of the literature difficult. Rhabdomyolysis (symptoms of muscle pain accompanied by increased creatine kinase >10 times ULN, increased serum creatine and brown colored urine) occurs rarely with all the statins. Muscle symptoms with the statins appear to be dose related, and the intensive dose statins should be used with caution in patients at increased risk of myotoxicity.
  - One meta-analysis [CTTC 2004] reported an overall low incidence of rhabdomyolysis with simvastatin, pravastatin, lovastatin and fluvastatin that did not differ from placebo (0.023% with the statins vs. 0.015% with placebo).
  - Rosuvastatin was associated with an incidence rate of rhabdomyolysis two times higher than that of the other marketed statins after the first six months of therapy (hazard ratio 1.98; [95% CI 0.18 to 21.90] in one retrospective cohort study of health claims. [McAfee 2006]. This result was not statistically significant. The analysis excluded cerivastatin (Baycol), as it was removed from the market in 2001 due to a high risk of rhabdomyolysis.
  - Spontaneous adverse event reporting data from the FDA uses a reporting rate (number of spontaneous case reports for rhabdomyolysis per 1 million US prescriptions) instead of an incidence rate to determine differences in myotoxicity between the statins.
    - Cerivastatin had the highest reporting rate of rhabdomyolysis (72.88 per 1 million US prescriptions) based on data from the years 1988 to 2000 were analyzed, while it was still marketed.
    - Data from 2002 to 2004 show that the reporting rate of rhabdomyolysis is higher with rosuvastatin at 13.54 reports per 1 million prescriptions, compared to simvastatin (8.71), fluvastatin (3.44), lovastatin (2.76), atorvastatin (1.67) and pravastatin (1.63).
    - Limitations to the FDA reporting system include the lack of a control group, reliance on spontaneous reports which may not reflect the true incidence of an adverse event, and the low overall occurrence of rhabdomyolysis. FDA reporting rates are more useful to signal a trigger of concern, rather than to quantify relative risks between different drugs in a class.
    - Despite the differences between rosuvastatin and the other marketed statins in terms of reporting rates and incidence rates of myotoxicity, definitive conclusions cannot be drawn. However, concerns remain with rosuvastatin, particularly at intensive doses.

Drug interactions: Fluvastatin, pravastatin, and rosuvastatin have the most favorable drug-drug interaction profiles as they are not appreciably metabolized via the CYP3A4 system. Atorvastatin, lovastatin, and simvastatin do undergo CYP3A4 metabolism, which results in concerns of drug-drug interactions with amiodarone, diltiazem, "azoles", and other 3A4 metabolized drugs.

Special populations: Fluvastatin, pravastatin, and rosuvastatin are preferred in patients with renal or hepatic insufficiency, in HIV/AIDS patients, or in recipients of solid organ transplants, as they are not metabolized via the CYP3A4 system. These patient groups represent about 2 to 3% of the 9 million DoD beneficiaries.

Pediatrics: Pravastatin is approved by the FDA for use in children as young as 8 years old. Atorvastatin, simvastatin, and lovastatin are approved for use in children as young as 10 years with heterozygous familial hypercholesterolemia, a rare condition.

Pregnancy: All the statins are rated Pregnancy Category X, due to the risk of fetal malformations.

Tolerability: There is insufficient evidence to determine whether one statin is less tolerable than another due to a lack of meta-analyses or retrospective claims data evaluating this outcome and the varying results reported in head-to-head trials.

4) *Other Factors:*

Dosing titration and initiation: The statins can be initiated at maximum doses, with the exception of rosuvastatin 40 mg. Rosuvastatin 40 mg should only be initiated in patients failing to reach target LDL goals with rosuvastatin 20 mg.

Pleiotropic effects: The majority of the observational data suggesting pleiotropic benefit (e.g., beneficial effects other than LDL lowering) with the statins rests with atorvastatin. None of the pleiotropic markers (e.g., C-reactive protein,) have been shown consistently in randomized trials to cause CHD. There is insufficient evidence to determine the clinical applicability of differences between the statins in terms of pleiotropic effects.

Markers of atherosclerotic progression: Rosuvastatin 40 mg was shown to cause plaque regression in the ASTEROID trial, and atorvastatin 80 mg was shown to slow the progression of plaque formation in the REVERSAL trial; both trials used intravascular ultrasound. Benefits on carotid intima media thickness have been shown with all the statins, except for rosuvastatin for which there is no published study.

5) *Efficacy and safety of ezetimibe:*

- Ezetimibe lowers LDL by a mechanism distinct from that of the statins, as it inhibits absorption of dietary cholesterol.
- Use of ezetimibe as monotherapy attains 15 to 19% LDL lowering and provides a treatment option for patients who are at risk for statin adverse events. Use of ezetimibe in combination with low to moderate statin doses provides greater LDL lowering (12 to 20% LDL lowering) vs. increasing the statin dose alone (5 to 6% LDL lowering).

- The combination of ezetimibe with a statin can be used to reach target LDL goals when statin monotherapy has failed, or to avoid the potential risks with using intensive statin doses as monotherapy.
- The proven benefits of cardiovascular outcomes seen with the statins have yet to be duplicated with ezetimibe, as there are no published trials.
- The most common adverse events with ezetimibe are abdominal pain, diarrhea and headache. The risk of elevations in liver transaminases is slightly increased when ezetimibe is combined with a statin (1.3 to 2%) vs. using statin monotherapy (0.4%). To date, there are only rare case reports of myotoxicity and rhabdomyolysis.
- Current MHS utilization and provider opinion support the need for ezetimibe in the MHS.

6) *Efficacy and safety of ezetimibe/simvastatin:*

- The combination of simvastatin with ezetimibe provides additional efficacy for LDL lowering.
- Doses of ezetimibe/simvastatin greater than 10/20 mg provide 45% to more than 55% LDL lowering, allowing a treatment option in those 15 to 20% of DoD patients unable to meet goal LDL with simvastatin alone.
- The efficacy profile of ezetimibe/simvastatin reflects that of the individual components.
- To date, no clinically important increases in safety issues, such as risk of liver transaminase elevation or myotoxicity have been reported.

7) *Efficacy and safety of niacin*

- Niacin is FDA-approved to raise HDL (along with fibrates). Niacin can raise HDL by 25%, and can be used as monotherapy or in combination with other drugs.
- Clinical outcomes including reduced stroke, MI, and all-cause mortality have been reported with niacin.
- The formulation of niacin extended release is associated with a reduced risk of GI adverse events and hepatotoxicity compared to niacin immediate release or over the counter forms of long-acting niacin (Slo-Niacin).
- The risk of myotoxicity and drug-drug interactions is reduced when niacin is used in combination with a statin, vs. using the combination of fibrates with a statin.
- The benefits of niacin extended release are limited to those patients who can tolerate the associated adverse effects (flushing and GI disturbances).

8) *Clinical issues with lovastatin/niacin extended release, atorvastatin/amlodipine, lovastatin extended release, and fluvastatin extended release*

- Lovastatin/niacin extended release is difficult to initiate and titrate, since it is available in a fixed dose formulation.

- Atorvastatin/amlodipine contains a statin in combination with the dihydropyridine calcium channel blocker amlodipine. Amlodipine (Norvasc) was designated non-formulary under the UF in August 05. No outcomes trials have specifically assessed the benefits of the fixed dose Caduet formulation, and there is no evidence to suggest improved adherence or additional LDL lowering with the combination.
- Lovastatin extended release does not offer additional LDL lowering or safety benefits over lovastatin. Unlike lovastatin, lovastatin extended release is available in a 60 mg tablet, but does not attain a >45% LDL lowering.
- Fluvastatin extended release has proven benefits from one trial assessing revascularization (LIPS) and is a non-CYP3A4 metabolized statin. However, it does not offer additional benefits over fluvastatin immediate release and does not attain a >45% LDL lowering.
- Overall, these drugs do not offer additional clinical benefits over the other antilipidemic agents and have low utilization in the MHS (<5,000 Rxs/month dispensed).

9) A survey of MTF providers, including cardiologists, was overwhelmingly in support of simvastatin for treating the 80-85% of MHS patients requiring LDL lowering <45%, and also supported use of ezetimibe. Providers were also concerned with the safety profile of rosuvastatin.

Overall Clinical Effectiveness Conclusion – The Committee concluded that:

1) Across equipotent doses, the statins achieve similar %LDL lowering, with rosuvastatin 40 mg and ezetimibe/simvastatin 10/80 mg as the only statins capable of attaining LDL lowering >55%.
2) Across equipotent doses, the statins achieve similar %HDL raising ability, but all statins show a plateau and drop-off of HDL raising effect at increasing doses.
3) There are no head-to-head trials comparing equivalent doses of statins that evaluate clinical outcomes for reducing mortality or other clinical outcomes (e.g., myocardial infarction, stroke, need for revascularization).
4) In low to moderate doses, the effects of atorvastatin, pravastatin and simvastatin appear similar for long-term cardiovascular protection, based on one meta-analysis (Zhou 2006).
5) In trials assessing the primary prevention of coronary heart disease (CHD), beneficial effects on clinical outcomes have been noted with atorvastatin 10 mg, lovastatin 20 to 40 mg, pravastatin 40 mg, and simvastatin 40 mg.
6) In trials assessing the secondary prevention of coronary heart disease (CHD), beneficial effects on clinical outcomes have been noted with atorvastatin 10 to 80 mg, lovastatin 40 to 80 mg, pravastatin 40 mg, simvastatin 20-40 mg, and fluvastatin 40 mg (administered BID).

7) In one trial assessing acute coronary syndrome (ACS) patients, beneficial effects on clinical outcomes were noted with atorvastatin 80 mg when it was compared to pravastatin 40 mg (PROVE-IT 2004).

8) There are no published trials assessing the benefits of rosuvastatin on clinical outcomes.

9) There is no evidence that increases in liver function tests (ALT) or minor adverse events (GI disturbances, headaches, rash, itching) are less likely to occur with one statin vs. another, and these adverse effects are dose-related.

10) Concerns of proteinuria and myotoxicity remain with rosuvastatin; the overall incidence of rhabdomyolysis occurs rarely with statins.

11) Fluvastatin, pravastatin, and rosuvastatin have the most favorable drug-drug interaction profiles,

12) There is insufficient evidence to determine whether one statin is less tolerable than another.

13) In terms of other factors, the statins can be initiated at maximum doses, with the exception of rosuvastatin 40 mg.

14) There is insufficient evidence to determine the clinical applicability of differences between the statins in terms of pleiotropic effects or effects on markers of atherosclerotic progression (intravascular ultrasound or carotid intima media thickness).

15) Ezetimibe offers an additional 15-20% LDL lowering by a mechanism distinct to that of the statins, but has not yet been evaluated for clinical outcomes.

16) Ezetimibe/simvastatin provides added efficacy in terms of LDL lowering and has a safety and efficacy profile reflecting that of its two individual components.

17) Niacin extended release is required in the MHS as its primary benefit is to raise HDL by 25%.

18) Lovastatin/niacin extended release, atorvastatin/amlodipine, lovastatin extended release, and fluvastatin extended release do not offer additional clinical benefits over the other LIP-1 agents and have low utilization in the MHS (<5,000 Rxs/month dispensed).

19) A survey of MTF providers, including cardiologists, was overwhelmingly in support of simvastatin for treating the 80-85% of MHS patients requiring LDL lowering ≤45%, and also supported use of ezetimibe.

20) Based on clinical issues alone, none of the LIP-1 agents are sufficiently less effective than the others agents within the class to be classified as non-formulary.

COMMITTEE ACTION: The P&T Committee voted (17 for, 0 opposed, 0 abstained, 0 absent) to accept the clinical effectiveness conclusions stated above.

B. LIP-1 Relative Cost Effectiveness

The P&T Committee evaluated the relative cost-effectiveness of the LIP-1 agents in relation to the effectiveness, safety, tolerability, and clinical outcomes of the other agents

in the class. Information considered by the P&T Committee included, but was not limited to, sources of information listed in 32 CFR 199.21(e)(2). A series of cost-effectiveness analyses were used to determine the relative cost-effectiveness of agents within the LIP-1 therapeutic class.

For the high % LDL lowering agents (>45%, intensive) in the LIP-1 class (atorvastatin 40 and 80 mg; rosuvastatin 10, 20, and 40 mg; ezetimibe/simvastatin 10/20, 10/40, and 10/80 mg; and simvastatin 80 mg), four separate cost-effectiveness models were constructed.

1) The Annual Cost per 1% LDL Decrease model compared the cost-effectiveness of the high % LDL lowering agents on annual cost per 1% LDL decrease using a decision analytical model.
2) The Annual Cost per Patient Treated to Goal model compared the cost-effectiveness of these agents on annual cost per patient successfully treated to NCEP goal using a Monte Carlo simulation model.
3) The Medical Cost Offset Model compared the cost-effectiveness of these agents based on their predicted outcomes and total predicted health care expenditures for CHD and CHD risk-equivalent patients.
4) The Cost per Event-Free Patient model, based on the results of the IDEAL Trial, compared the cost-effectiveness of the agents included in that trial – high-dose (80mg) atorvastatin (Lipitor) vs. low-dose (20-40 mg) simvastatin – using a decision analytic model.

The results of the first three cost-effectiveness analyses showed ezetimibe/simvastatin (Vytorin) to be the most cost effective high % LDL lowering agent. The results of the fourth analysis revealed that high-dose (80 mg) atorvastatin was more effective but considerably more costly compared to low dose (20-40mg) simvastatin. The results of this analysis support use of high dose atorvastatin only in patients who cannot be successfully treated to goal with simvastatin.

For the low to moderate % LDL lowering agents (≤ 45%) in the LIP-1 class (simvastatin 5, 10, 20, and 40 mg, atorvastatin 10 and 20 mg; rosuvastatin 5 mg; ezetimibe/simvastatin 10/10 mg; and all strengths of pravastatin, fluvastatin, fluvastatin extended release lovastatin, lovastatin extended release, niacin/lovastatin, niacin extended release, niacin immediate release, and ezetimibe), the cost-effectiveness of the agents within this subclass was evaluated using the Annual Cost per 1% LDL Decrease model. In pharmacoeconomic terms, lovastatin, lovastatin extended release, simvastatin, and rosuvastatin were located along the cost efficiency frontier and were considered to be the optimal agents. Although these agents differed in terms of cost-effectiveness relative to each other, they were more cost-effective than (dominated) the other agents evaluated.

With respect to atorvastatin/amlodipine, an earlier review did not show additional clinical benefit for amlodipine versus other dihydropyridine CCBs. Single ingredient amlodipine (Norvasc) is non-formulary under the UF. In order to assess the cost effectiveness of atorvastatin/amlodipine, it was compared to the combination of atorvastatin and a UF dihydropyridine calcium channel blocker, based on the weighted average cost per day of therapy. The results of this analysis revealed that atorvastatin/amlodipine was

considerably more costly compared to the combination of atorvastatin and a UF dihydropyridine calcium channel blocker, regardless of point of service.

To account for other factors and costs associated with a UF decision (market share migration, switch costs, non-formulary cost shares, and medical necessity processing fees), a budget impact analysis was performed. The goal of the BIA was to assist the Committee in determining which group of high % LDL lowering LIP-1 agents best met the majority of the clinical needs of the DoD population at the lowest cost to the MHS. The BIA focused on high % LDL lowering agents because 1) simvastatin could meet the vast majority of the needs of patients requiring low % LDL lowering agents; 2) some low % LDL lowering agents were considered to be clinically necessary (pravastatin, ezetimibe, and niacin extended release); and 3) of the remaining low % LDL lowering agents, nothing would be gained clinically or economically by making them non-formulary, especially considering their low market share. Based on the BIA results and other clinical and cost considerations, the Committee agreed that the UF scenario that included the high % LDL lowering agents atorvastatin and ezetimibe/simvastatin on the UF best achieved this goal when compared to other alternative UF scenarios, and thus was determined to be more cost-effective relative to other UF scenarios.

Conclusion: The P&T Committee, based upon its collective professional judgment, voted (17 for, 0 opposed, 0 abstention, and 0 absent) to accept the LIP-1 relative cost-effectiveness analysis as presented by the PEC. The P&T Committee concluded that the Uniform Formulary scenario that included atorvastatin, ezetimibe/simvastatin, and simvastatin 80 mg as the high % LDL lowering agents on the UF was the most cost effective UF scenario.

COMMITTEE ACTION – Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of the LIP-1 agents, and other relevant factors, the P&T Committee, based upon its collective professional judgment, voted (15 for, 1 opposed, 1 abstained, and 0 absent) to recommend that atorvastatin, fluvastatin immediate and extended release, pravastatin, simvastatin, lovastatin immediate and extended release, lovastatin/niacin, ezetimibe/simvastatin, niacin immediate and extended release, and ezetimibe be maintained as formulary on the UF and that rosuvastatin and atorvastatin/amlodipine be classified as non-formulary under the UF.

C. LIP-1 UF Medical Necessity Criteria

Based on the clinical evaluation of the LIP-1 agents, and the conditions for establishing medical necessity for a non-formulary medication provided for in the UF rule, the P&T Committee recommended the following general medical necessity criteria for rosuvastatin:

1) Use of formulary alternatives is contraindicated.
2) The patient has experienced or is likely to experience significant adverse effects from formulary alternatives.
3) Treatment with the formulary alternatives has resulted, or is likely to result, in therapeutic failure.
4) The patient previously responded to rosuvastatin and changing to a formulary alternative would incur unacceptable clinical risk.

The P&T Committee noted that some specific situations in which rosuvastatin might be considered medically necessarily were 1) if a patient requires a high % LDL lowering agent in order to meet his or her LDL goal *and* requires a non-CYP3A4-metabolized statin due to potential drug interactions, or 2) if a patient requires a high % LDL lowering agent in order to met his or her LDL goal *and* is not able to reach that goal with any of the formulary high % LDL lowering agents. The P&T Committee also noted that criterion #4 would apply rarely, since changes in statin therapy are unlikely to present a risk of destabilization or serious adverse effects in the vast majority of patients and since rosuvastatin does not offer any significant safety advantages compared to other statins other than not being metabolized through CYP3A4.

Based on the clinical evaluation of the LIP-1 agents, and the conditions for establishing medical necessity for a non-formulary medication provided for in the UF rule, the P&T Committee recommended the following medical necessity criterion for atorvastatin/ amlodipine:

1) Use of formulary alternatives is contraindicated.

The P&T Committee noted that the other conditions for establishing medical necessity provided for in the UF rule do not apply to atorvastatin/amlodipine since the components of this product are available as single ingredients and there is no evidence to support improved efficacy, safety, or tolerability with the combination product vs. its individual components given separately. Amlodipine, a dihydropyridine calcium channel blocker used for hypertension and coronary artery disease, has not been shown to enhance the lipid-lowering effects of atorvastatin. The P&T Committee further noted that since single ingredient amlodipine is non-formulary under the UF, the closest therapeutic alternative to atorvastatin/amlodipine on the UF would be atorvastatin or another UF statin plus a UF dihydropyridine calcium channel blocker [felodipine (Plendil, generics), nifedipine extended release (Adalat CC, Procardia XL, generics), or nisoldipine (Sular)].

COMMITTEE ACTION: The P&T Committee voted (15 for, 0 opposed, 1 abstained, 1 absent) to approve the medical necessity criteria outlined above.

D. LIP-1 Implementation Plan:

Because of contractual considerations associated with the statin drug class affecting MTFs and TMOP, the P&T Committee recommended an effective date no sooner than the first Wednesday following a 90-day implementation period. The implementation period will begin immediately following approval by the Director, TMA.

MTFs will not be allowed to have rosuvastatin or atorvastatin/amlodipine on their local formularies. MTFs will be able to fill non-formulary requests for these agents only if both of the following conditions are met: 1) the prescription must be written by a MTF provider, and 2) medical necessity is established. MTFs may (but are not required to) fill a prescription for non-formulary LIP-1 agents written by a non-MTF provider to whom the patient was referred, as long as medical necessity has been established.

COMMITTEE ACTION: The P&T Committee recommended (15 for, 0 opposed, 2 abstained, 0 absent) an effective date no sooner than the first Wednesday following a 90-day implementation period. The implementation period will begin immediately following the approval by the Director, TMA.

E. LIP-1 BCF Review and Recommendations

The P&T Committee had previously determined that one or more low to moderate % LDL lowering agents and no more than one high % LDL lowering agent could be considered for addition to the BCF. Based on the relative clinical effectiveness and cost effectiveness of the agents and taking into account the following considerations, the P&T Committee recommended the following LIP-1 agents for BCF status:

- *Simvastatin* – Simvastatin provides LDL-lowering of up to 40 to 45% at doses ≤ 40 mg/day; can be used to treat 85% of MHS patients who require a statin; has shown proven mortality benefits in primary and secondary prevention trials [HPS; 4S]; is labeled for pediatric use in patients as young as 10 years of age; has an acceptable adverse event profile compared to other statins; and is familiar to MHS providers as evidenced by its current high utilization in the MHS.
- *Pravastatin* – Pravastatin is one of three statins not metabolized via the CYP3A4 system, which is necessary in order to avoid drug interactions in special populations *requiring* treatment with interacting medications (e.g., HIV/AIDS patients, solid organ transplant patients); has shown proven mortality benefits in primary and secondary prevention trials [WOSCOPS, CARE, LIPID]; is labeled for pediatric use in patients as young as 8 years of age; and has the highest utilization in the MHS of the three non-CYP3A4-metabolized statins.
- *Ezetimibe/simvastatin*– The combination of simvastatin and ezetimibe provides additional efficacy for LDL lowering; the 45% to more than 55% LDL lowering attainable with doses higher than 10/20 mg can be used to treat the estimated 15 to 20% of patients who cannot meet goal with simvastatin alone.
- *Niacin extended release* – Niacin is the only agent in the class that has been shown to raise HDL by 25%; has shown proven benefits for mortality, MI, and stroke [Coronary Drug Project]; and has a lower risk for GI adverse events and hepatotoxicity compared to other niacin formulations.

The Committee commented that while atorvastatin is recommended to remain on the UF, MTFs are strongly advised to avoid adding it to local formularies. Simvastatin doses of 20 to 40 mg provide similar efficacy for LDL lowering as atorvastatin but 10 to 20 mg, at a much lower cost due to generic availability. Patient migration from simvastatin to atorvastatin, particularly for patients requiring lower doses, will erode the cost-savings anticipated to occur as generic prices for simvastatin continue to decrease without providing additional clinical benefit. One possible exception to this may be ACS patients, in whom atorvastatin may be preferable based on the results of the PROVE-IT trial (for most patients, this would most likely entail use of 80 mg dose of atorvastatin, based on the lower LDL goals in this patient population).

COMMITTEE ACTION: The P&T Committee voted (15 for, 1 opposed, 1 abstained, 0 absent) to recommend simvastatin, pravastatin, ezetimibe/simvastatin and niacin extended release as the BCF selections in this drug class.

10. CLASS OVERVIEWS. ATTENTION-DEFICIT / HYPERACTIVITY DISORDER AND NARCOLEPSY MEDICATIONS; SEDATIVE HYPNOTICS I (NON-BENZO-DIAZEPINE SEDATIVE HYPNOTICS); SEDATIVE HYPNOTICS II

Portions of the clinical reviews for each class were presented to the Committee. The Committee provided expert opinion regarding those clinical outcomes considered most important for the PEC to use in completing the clinical effectiveness review, and for developing the appropriate cost effectiveness models. Both the clinical and economic analyses of these three classes will be completed during the November 2006 meeting; no action necessary.

11. ADJOURNMENT

The second day of the meeting adjourned at 1600 hours on 16 August 2006. The dates of the next meeting are 14-16 November 2006.

Appendix B – Table 2. Newly Approved Drugs. August 2006 DoD P&T Committee Meeting

Medication (Brand name; manufacturer) mechanism of action	**FDA Approval Date & FDA-Approved Indications**	**Committee Recommendation**
Dasatinib tabs (Sprycel; BMS) oral multi-kinase inhibitor	Jun 06 ▪ Treatment of adults with chronic, accelerated, or myeloid or lymphoid blast phase chronic myeloid leukemia with resistance or intolerance to prior therapy including imatinib (Gleevec) ▪ Treatment of adults with Philadelphia chromosome-positive acute lymphoblastic leukemia with resistance or intolerance to prior therapy	No UF recommendation at this meeting. Consideration of UF status deferred until oral cancer medications reviewed. Quantity limits recommended: ▪ TMOP o Days supply limit 45 days o 20 mg: 180 tabs per 45 days o 50 mg: 180 tabs per 45 days o 70 mg: 90 tabs per 45 days ▪ Retail Network o Days supply limit 30 days o 20 mg: 120 tabs per 30 days o 50 mg: 120 tabs per 30 days o 70 mg: 60 tabs per 30 days
Selegiline transdermal system (Emsam; BMS / Somerset) MAO A/B inhibitor	Mar 06 ▪ Acute and longer-term treatment of major depressive disorder in adult patients	No UF recommendation at this meeting. Consideration of UF status deferred until MAO inhibitors reviewed.
Rasagiline tabs (Azilect; Teva) MAO B inhibitor	May 06 ▪ Treatment as monotherapy of early Parkinson's Disease and combination use with levodopa in patients with moderate to advanced stages of Parkinson's Disease	No UF recommendation at this meeting. Consideration of UF status deferred until Parkinson's medications reviewed.
Methylphenidate transdermal system (Daytrana; Shire/Noven) amphetamine	Apr 06 ▪ Treatment of attention deficit hyperactive disorder (ADHD) in children 6-12 yrs of age	No UF recommendation at this meeting. Consideration of UF status deferred until ADHD / narcolepsy drug class reviewed in Nov 06.
Lubiprostone caps (Amitiza; Sucampo / Takeda) chloride channel activator	Jan 06 ▪ Treatment of chronic idiopathic constipation in adults	No UF recommendation at this meeting. Consideration of UF status deferred until drug class reviewed.

DECISION PAPER:

May 2006
DEPARTMENT OF DEFENSE PHARMACY AND THERAPEUTICS COMMITTEE RECOMMENDATIONS

1. **CONVENING**
2. **ATTENDANCE**
3. **REVIEW MINUTES OF LAST MEETING**
4. **ITEMS FOR INFORMATION**
5. **REVIEW OF RECENTLY APPROVED AGENTS**

The P&T Committee was briefed on six new drugs that had been approved by the Food and Drug Administration (FDA). None of the medications fall into drug classes already reviewed by the P&T Committee, therefore Uniform Formulary (UF) consideration was deferred until the corresponding drug class reviews are completed. The Committee reviewed one new drug for quantity limits. Sunitinib (Sutent) is an oral multi-kinase inhibitor approved for treatment of patients with advanced renal cell carcinoma and for the treatment of gastrointestinal stromal tumor (GIST). It is available in 12.5, 25 and 50 mg capsules and is administered once daily for a schedule of four weeks on treatment followed by two weeks off treatment. Quantity limits were recommended for sunitinib since there is a risk of discontinuation of therapy due to poor patient prognosis or drug-related adverse effects, and due to the dosing regimen. Other oral chemotherapy drugs (imatinib, erlortinib, sorafenib) also have quantity limits.

COMMITTEE ACTION: The DoD Pharmacy and Therapeutics (P&T) Committee voted (15 for, 0 opposed, 1 abstained, 2 absent) to recommend that sunitinib (Sutent) have quantity limits in the TRICARE Mail Order Pharmacy (TMOP) Program of 60 capsules for the 50 mg formulation, 120 capsules for the 25 mg formulation, and 180 capsules for the 12.5 mg formulation per 84 days. In the TRICARE Retail Pharmacy Network (TRRx), the recommended quantity limits were 30 capsules for the 50 mg formulation, 60 capsules for the 25 mg formulation, and 120 capsules for the 12.5 mg formulation per 30 days. (See paragraph 5 on pages 10-11 of the P&T Committee minutes).

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

6. QUANTITY LIMITS:

A. ORAL TRANSMUCOSAL FENTANYL CITRATE (ACTIQ) – Actiq is indicated only for breakthrough cancer pain in patients already receiving opioids and who are opioid tolerant, with a recommended daily maximum of four or fewer units ("lollipops") per day. If consumption increases to more than four per day, the dose of the long-acting opioid for persistent cancer pain

should be reevaluated. The Committee agreed that a quantity limit of 120 units per 30 days, 360 units per 90 days should be established for Actiq, based on the daily maximum of four per day recommended in product labeling, in order to address potential concerns of overuse (i.e., use in lieu of appropriate increases in long-acting opioid treatment) and diversion.

***COMMITTEE ACTION*.** The Committee voted (13 for, 1 opposed, 1 abstained, 3 absent) to recommend that a quantity limit of 120 units per 30 days, 360 units per 90 days be established for oral transmucosal fentanyl citrate (Actiq). (See paragraph 6A on page 11 of P&T Committee minutes for rationale).

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

B. Rizatriptan (Maxalt, Maxalt MLT) – The current quantity limit for rizatriptan tablets and orally disintegrating tablets (Maxalt, Maxalt MLT) is 12 tablets per 30 days, or 36 tablets per 90 days, which is consistent with the maximum recommended dose in product labeling. However, rizatriptan tablets are now available in packages of nine rather than six tablets. The Committee agreed that the 30-day quantity limit for rizatriptan tablets should be increased to 18 tablets, but that the 90-day quantity limit should remain at 36 tablets. This quantity limit would take into account the fact that a substantial number of patients currently fill prescriptions at the maximum quantity limit of 12 tablets per 30 days, allow for dispensing of whole packages, and avoid increasing the 90-day limit to 54 tablets (3 times 18), which is in excess of safety recommendations and not consistent with quantity limits for other triptans.

***COMMITTEE ACTION*.** The Committee voted (15 for, 0 opposed, 0 abstained, 3 absent) to recommend changing the quantity limit for rizatriptan tablets and orally disintegrating tablets (Maxalt, Maxalt MLT) to 18 tablets per 30 days, or 36 tablets per 90 days. (See paragraph 6B on pages 11-12 of P&T Committee minutes for rationale).

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

7. ANTIEMETIC DRUG CLASS REVIEW

The P&T Committee evaluated the relative clinical effectiveness and cost-effectiveness of the antiemetic agents marketed in the United States. The drugs in the class were broken into two subclasses, newer and older antiemetics. The newer agents include the type 3 serotonin receptor (5-HT3) antagonists ondansetron (Zofran), granisetron (Kytril), and dolasetron (Anzemet); and the neurokinin-1 (NK-1) receptor antagonist aprepitant (Emend). The older antiemetic subclass is comprised of the cannabinoid dronabinol (Marinol); the phenothiazines prochlorperazine and thiethylperazine (Torecan); the antihistamines meclizine and promethazine; and the anticholinergics transdermal scopolamine (Transderm Scop) and trimethobenzamide. The newer and older antiemetics together account for approximately $37.4 million dollars annually, and are ranked 48th in Military Health System (MHS) drug class expenditures.

The Committee voted (16 for, 0 opposed, 0 abstained, 2 absent) that: (1) the 5-HT3 antagonists ondansetron, granisetron and dolasetron have shown similar complete response rates in patients with chemotherapy-induced nausea and vomiting (CINV), radiation-induced nausea and vomiting (RINV), and post-operative nausea and vomiting (PONV); (2) the NK-1 receptor antagonist aprepitant serves a unique role in preventing CINV caused by highly emetogenic chemotherapy regimens and is required for adequate clinical coverage; (3) for nausea and vomiting in pregnancy, ondansetron should be reserved for use as third-line therapy in pregnant women requiring intravenous hydration who have not responded to other therapies; (4) there is insufficient evidence to suggest that there are major differences in the adverse effect profiles of the 5-HT3 antagonists or aprepitant; headache and gastrointestinal effects are the most commonly reported adverse events; (5) aprepitant is the newer antiemetic that has the most clinically important drug interaction profile, due to its metabolism via the CYP3A4 enzyme system; (6) there are differences among the newer antiemetics in terms of availability of oral formulations, approval for use in children, and number of FDA-approved indications; (7) none of the newer antiemetics are sufficiently less clinically effective than the others to be classified as non-formulary based on clinical issues alone; (8) none of the older antiemetics has a significant, clinically meaningful therapeutic disadvantage in terms of safety, effectiveness , or clinical outcome compared to the other agents to warrant classification as non-formulary, based on clinical issues alone.

Based on the results of the cost-effectiveness analysis (CEA) and other clinical and cost considerations, the Committee concluded (16 for, 0 opposed, 0 abstained, 2 absent) that granisetron and ondansetron were the more cost effective 5HT-3 antiemetic drugs; that it is also cost-effective for aprepitant to be used as an adjunct for the treatment of CINV; and that the older antiemetics are all relatively cost-effective.

A. COMMITTEE ACTION: Taking into consideration the conclusions from the relative clinical effectiveness and the relative cost effectiveness determinations for the anti-emetic drugs, and other relevant factors, the P&T Committee voted (14 for, 1 opposed, 2 absent, 1 abstained) to recommend that dolasetron be classified as non-formulary under the UF, with granisetron, ondansetron, aprepitant, dronabinol, meclizine, prochlorperazine, promethazine, scopolamine, thiethylperazine, and trimethobenzamide remaining on the UF. (See paragraphs 7A and 7B on pages 12-18 P&T Committee minutes)

In addition, the P&T Committee agreed that the current quantity limits for the newer antiemetics should remain unchanged; it also agreed that a more systematic set of criteria addressing severe nausea and vomiting associated with pregnancy should be developed to assist military treatment facilities (MTFs).

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

B. COMMITTEE ACTION: Based on the clinical evaluation of dolasetron (Anzemet) and the conditions for establishing medical necessity for a non-formulary medication provided in the

UF rule, the P&T Committee recommended (15 for, 0 opposed, 1 abstained, 2 absent) medical necessity criteria for the antiemetics. (See paragraphs 7C on page 18 of the P&T Committee minutes for criteria.)

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

C. COMMITTEE ACTION: The P & T Committee voted (14 for, 1 opposed, 1 abstained, 2 absent) to recommend an effective date no later than the first Wednesday following an implementation period of 60 days. The implementation will begin immediately following the approval of director, TMA. (See paragraph 7D on pages 18-19 of the P&T Committee minutes for criteria.)

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

D. COMMITTEE ACTION: Based on the relative clinical and cost-effectiveness analysis, the P & T Committee voted (15 for, 0 opposed, 1 abstained, 2 absent) to recommend oral and rectal promethazine as the Basic Core Formulary (BCF) agent. (See paragraphs 7E on page 19 of the P&T Committee minutes)

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

8. CONTRACEPTIVE AGENTS DRUG CLASS REVIEW

The P&T Committee evaluated the relative clinical effectiveness of the oral, transdermal, injectable, and vaginal ring contraceptives available in the U.S. A total of 36 products were divided into 11 subgroups, based on estrogen content, phasic formulation, and route of administration. The P&T Committee concluded (15 for, 0 opposed, 0 abstained, 3 absent) that: 1) contraceptives vary in estrogen content, progestin content, regimen (e.g., extended use), phasic formulation, desirability for non-contraceptive uses, and routes of administration; 2) there is wide intra- and inter-patient variability in pharmacokinetics; 3) differences may affect safety, adverse effects/tolerability, convenience/compliance, or effectiveness for non-contraceptive uses; 4) there do not appear to be substantial differences in contraceptive effectiveness across products; 5) providers desire a wide variety of choices (based on both estrogen and progestogen content), patient response is variable, and there are clinical niches for which multiple choices are required; 6) the alternative formulations (vaginal ring, patch, intramuscular and subcutaneous injection) are required for adequate clinical coverage; 7) none of the reviewed contraceptives are sufficiently less clinically effective than others to be classified as non-formulary based on clinical issues alone.

Based on the results of the CEA and other clinical and cost considerations, the P&T Committee agreed (15 for, 0 opposed, 0 abstained, 3 absent) that: 1) all generically available oral contraceptives (OCs) should remain on the UF, because they are generally more cost-effective than brand name contraceptives and non-orally administered contraceptives and because further opportunity exists to negotiate lower prices for generic agents through contracting; 2) all of the non-oral products (Nuvaring, Ortho Evra, Depo Provera and equivalents, Depo-subq Provera 104) should remain on the UF to ensure clinical coverage for patients who need these methods of administration; 3) the brand-only products Yasmin, Yaz, and Ortho Tri-Cyclen Lo should remain on the UF, because they offer clinical and/or economic value; and 4) the brand-only products Seasonale, Ovcon-35, Ovcon-50, and Estrostep Fe should be classified as non-formulary under the UF, because clinically similar alternatives are available at a significantly lower cost. The P&T Committee also agreed (12 for, 1 opposed, 3 abstained, 2 absent) that Plan B should continue on the UF because of the clinical advantages of this progestogen-only product over other OCs for emergency contraception.

In addition, the P&T Committee voted (11 for, 2 opposed, 3 abstained, 2 absent) to recommend that Plan B be available from the TMOP, with a quantity limit of one Plan B package per co-pay applying to purchased care prescriptions.

A. COMMITTEE ACTION: Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations, and other relevant factors, the P&T Committee voted (14 for, 0 opposed, 1 abstained, 3 absent) to recommend that Seasonale (EE 30 mcg; levonorgestrel 0.15 mg in special packaging for extended use); Ovcon 35 (EE 35 mcg; 0.4 mg norethindrone); Ovcon 50 (EE 50 mcg; norethindrone 1 mg), and Estrostep Fe (EE 20/30/35 mcg; norethindrone 1 mg) be classified as non-formulary under the UF and that the brand-only products Yasmin, Yaz, Ortho Tri-Cyclen Lo, Ortho Evra, Nuvaring, Depo-Provera, Depo-subq Provera 104, and all generically-available products listed in Table 1 (on pages 18-19 of the P&T Committee minutes) be classified as formulary on the UF. The P&T Committee voted (12 for, 1 opposed, 3 abstained, 2 absent) that Plan B should continue to be classified as formulary on the UF. (See paragraphs 8A and 8B on pages 19-30 of P&T Committee minutes)

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

B. COMMITTEE ACTION: Based on the clinical evaluation of the contraceptive agents and the conditions for establishing medical necessity for a non-formulary medication provided for in the UF rule, the P&T Committee recommended (14 for, 0 opposed, 1 abstained, 3 absent) medical necessity criteria for the contraceptive agents. (See 8C on page 30 of P&T Committee minutes for criteria.)

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

C. COMMITTEE ACTION: The P&T Committee recommended (14 for, 0 opposed, 1 abstained, 3 absent) an effective date no later than the first Wednesday following a 180-day implementation period. The implementation period will begin immediately following the approval by the Director, TMA. (See paragraph 8D on pages 30-31 of P&T Committee minutes for rationale)

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

D. COMMITTEE ACTION: Based on the relative clinical and cost effectiveness analyses, the P&T Committee voted (14 for, 0 opposed, 1 abstained, 3 absent) to recommend the following products as the BCF agents.

- EE 20 mcg; 3 mg drospirenone (Yaz)
- EE 20 mcg; 0.1 mg levonorgestrel (Alesse, Levlite, or equivalent)
- EE 30 mcg; 3 mg drospirenone (Yasmin)
- EE 30 mcg; levonorgestrel 0.15 mg (Nordette or equivalent; excludes Seasonale)
- EE 35 mcg; 1 mg norethindrone (Ortho-Novum 1/35 or equivalent)
- EE 35 mcg; 0.25 mg norgestimate (Ortho-Cyclen or equivalent)
- EE 25 mcg; 0.18/0.215/0.25 mg norgestimate (Ortho Tri-Cyclen Lo)
- EE 35 mcg; 0.18/0.215/0.25 mg norgestimate (Ortho Tri-Cyclen or equivalent)
- 0.35 mg norethindrone (Nor-QD, Ortho Micronor, or equivalent)

(See paragraph 8E on pages 31-32 of P&T Committee minutes for rationale.)

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

9. ABBREVIATED CLASS REVIEWS: HISTAMINE-2 (H2) BLOCKERS; HMG-Co A REDUCTASE INHIBITORS (STATINS), COMBINATION PRODUCTS, AND ADD-ON THERAPIES OF EZETIMIBE AND NIACIN; AND NEWER SEDATIVE HYPNOTIC AGENTS

Portions of the clinical reviews for each class were presented to the Committee. The Committee provided expert opinion regarding those clinical outcomes considered most important for the PEC to use in completing the clinical effectiveness review, and for developing the appropriate cost effectiveness models. Both the clinical and economic analyses of these three classes will be completed during the August 2006 meeting; no action necessary.

APPENDIX A – TABLE 1: Implementation status of UF Decisions

APPENDIX B – TABLE 2: Newly Approved Drugs

APPENDIX C – TABLE 3: Abbreviations

DECISION ON RECOMMENDATIONS

Director, TMA, decisions are as annotated above.

Department of Defense
Pharmacy and Therapeutics Committee Minutes

11 May 2006

1. CONVENING

The Department of Defense (DoD) Pharmacy and Therapeutics (P&T) Committee convened at 0800 hours on 9 May 2006 at the DoD Pharmacoeconomic Center (PEC), Fort Sam Houston, Texas.

2. ATTENDANCE

A. Voting Members Present

CAPT Patricia Buss, MC, USN	DoD P& T Committee Chair
CDR Mark Richerson, MSC, USN	DoD P& T Committee Recorder
CAPT Bill Blanche, MSC, USN	DoD Pharmacy Programs, TMA
Maj David Carnahan, MC	Air Force, Internal Medicine Physician
Maj Michael Proffitt, MC	Air Force, OB/GYN Physician
LtCol Brian Crownover, MC	Air Force, Physician at Large
LtCol Charlene Reith *for* LtCol Everett McAllister, BSC	Air Force, Pharmacy Officer
CDR Brian Alexander, MC	Navy, Physician at Large
LCDR Joe Lawrence MSC *for* CAPT David Price, MSC	Navy, Pharmacy Officer
COL Doreen Lounsbery, MC	Army, Internal Medicine Physician
MAJ Roger Brockbank, MC	Army, Family Practice Physician
COL Joel Schmidt, MC	Army, Physician at Large
LTC Peter Bulatao, MSC *for* COL Isiah Harper, MSC	Army, Pharmacy Officer
CDR Vernon Lew, USPHS	Coast Guard, Pharmacy Officer
CDR Jill Pettit, MSC, USN	TMOP COR
Mr. Joe Canzolino	Department of Veterans Affairs

B. Voting Members Absent

LCDR Chris Hyun, MC	Navy, Internal Medicine Physician
LCDR Scott Akins, MC	Navy, Pediatrics Physician
CAPT David Price, MSC	Navy, Pharmacy Officer
LtCol Everett McAllister, BSC	Air Force, Pharmacy Officer
COL Isiah Harper, MSC	Army, Pharmacy Officer

C. Non-Voting Members Present

COL Kent Maneval, MSC, USA	Defense Medical Standardization Board
Mr. Lynn T. Burleson	Assistant General Counsel, TMA
Mr. John Felicio *for* Ms Martha Taft	Health Plan Operations, TMA
Major Peter Trang, BSC, USAF	Defense Supply Center Philadelphia

D. Non-Voting Members Absent

None	

E. Others Present

CAPT Don Nichols, MC, USN	DoD Pharmacoeconomic Center

Mr. David Meade	DoD Pharmacoeconomic Center
Ms Harsha Mistry	DoD Pharmacoeconomic Center
Ms Elaine Furmaga	Department of Veterans Affairs

3. REVIEW MINUTES OF LAST MEETING

A. Corrections to the minutes – February 2006 DoD P&T meeting minutes were approved as written, with no corrections noted.

B. February minutes approval – Dr. William Winkenwerder, Jr., M.D. approved the minutes of the February 2006 DoD P&T Committee on 26 April 2006.

4. ITEMS FOR INFORMATION

TMA and DoD PEC staff members briefed the P&T Committee on the following:

A. Interim Fluoroquinolone Basic Core Formulary (BCF) Administrative Action: CAPT Buss and CDR Richerson briefed the DoD P&T Committee on the justification and process employed for the 16 March 2006 fluoroquinolone administrative change to the BCF (replacement of gatifloxacin with levofloxacin).

B. Tikosyn Availability in the TRICARE Mail Order Pharmacy (TMOP) Program: Ms. Libby Hearin briefed the DoD P&T Committee that, as of 24 April 2006, Tikosyn is now available through the TMOP. This drug is an anti-arrhythmic which is subject to a controlled distribution program.

C. Beneficiary Advisory Panel (BAP) Briefing: CAPT Buss, CDR Richerson, and CPT Dacus briefed the members of the DoD P&T Committee regarding the 30 March 2006 BAP meeting. The Committee was briefed on BAP comments regarding DoD P&T Committee's Uniform Formulary (UF) and implementation recommendations.

D. Implementation Status of UF Decisions: Mr. Dave Bretzke briefed the members of the Committee on the progress of implementation for drug classes reviewed for UF status since August of 2005. The Committee made the following observations:

- Utilization in all UF classes continues to remain stable, suggesting continued access to drugs within the reviewed classes.
- Collective utilization of UF agents across all reviewed drug classes and points of service (military treatment facility (MTF), TMOP, TRICARE Retail Pharmacy (TRRx) Network) continues to increase as a percentage of prescriptions dispensed, while utilization of non-formulary agents has decreased. Based on the UF decisions that have been fully implemented since the first UF DoD P&T meeting in February 2005, there has been a 27% reduction in the use of non-formulary agents. Based on all drug classes reviewed by the Committee to date, including those classes where implementation has only just begun, there has been an 18% reduction in the use of agents designated as non-formulary.
- Success in terms of generating increased market share for UF agents (while decreasing market share for non-formulary agents) varies by class and by point of service.
- Market shares by point of service continue to reflect the degree of utilization management applied to each point of service. The more highly managed points of service (i.e., MTFs) are generating higher market shares of UF agents than the unmanaged points of service (i.e., TMOP and TRRx).
- For drug classes fully implemented, MTFs have reduced the use of non-formulary drugs by 81% as projected, but the decrease in the use of non-formulary medications at mail (-2%) and retail (-13%) is significantly less.
- It appears that more beneficiaries are electing to receive non-formulary medications through TMOP. It is unclear at this time whether these beneficiaries are former MTF patients or former TRRx patients.

5. REVIEW OF RECENTLY-APPROVED AGENTS

The P&T Committee was briefed on six new drugs that had been approved by the Food and Drug Administration (FDA). None of the medications fall into drug classes already reviewed by the P&T Committee; therefore, UF consideration was deferred until the corresponding drug class reviews are completed. The Committee reviewed one new drug for quantity limits. Sunitinib (Sutent) is an oral multi-kinase inhibitor approved for treatment of patients with advanced renal cell carcinoma and for the treatment of gastrointestinal stromal tumor (GIST). It is available in 12.5, 25 and 50 mg capsules and is administered once daily for a period of four weeks followed by two weeks off treatment. Dosage reductions are recommended in 12.5 mg intervals, if needed. There is no 37.5 mg capsule available. Quantity limits were recommended for sunitinib since there is a risk of discontinuation of therapy due to poor patient prognosis or

drug-related adverse effects, and likelihood of changes to individual dosing regimens. Other oral chemotherapy drugs (imatinib, erlortinib, sorafenib) also have quantity limits.

One of the new drugs, mecasermin rinfabate (Iplex), is a new version of a medication for which a prior authorization (PA) is already in place. Mecasermin rinfabate was added to the existing PA criteria and forms for mecasermin.

COMMITTEE ACTION: The P&T Committee voted (15 for, 0 against, 1 abstained, 2 absent) to recommend that sunitinib (Sutent) have quantity limits in the TMOP for 60 capsules for the 50 mg formulation, 120 capsules for the 25 mg formulation, and 180 capsules for the 12.5 mg formulation per 84 days. In the TRRx, the recommended quantity limits were 30 capsules for the 50 mg formulation, 60 capsules for the 25 mg formulation, and 120 capsules for the 12.5 mg formulation per 30 days.

6. QUANTITY LIMITS:

A. ORAL TRANSMUCOSAL FENTANYL CITRATE (ACTIQ) – Actiq is indicated only for breakthrough cancer pain in patients already receiving opioids and who are opioid tolerant. Based on safety recommendations in product labeling, the daily limit for Actiq is four or fewer units ("lollipops") per day. If consumption increases to more than four per day, the dose of the long-acting opioid for persistent cancer pain should be reevaluated. The product is available in multiple strengths—200, 400, 600, 800, 1200, and 1600 mcg—to accommodate individual patient needs and increases in opioid requirements associated with long-term opioid treatment.

The major potential concerns with Actiq are overuse (i.e., use in lieu of appropriate increases in long-acting opioid treatment) and diversion. Actiq is costly; average wholesale price per unit ranges from $17.40 to $51.40 per lollipop, with a federal supply schedule price of $4.89 to $14.56.

The Committee voted (13 for, 1 opposed, 1 abstained, 3 absent) to recommend that a quantity limit of 120 units per 30 days, 360 units per 90 days be established for Actiq, based on the daily maximum of four per day recommended in product labeling. The Committee noted that Express Scripts, Inc. (ESI), the contractor for the TMOP and TRRx programs, has established procedures to deal with circumstances that may require temporary overrides of quantity limits (e.g., increases in dose).

COMMITTEE ACTION: The Committee voted (13 for, 1 opposed, 1 abstained, 3 absent) to recommend that a quantity limit of 120 units per 30 days, 360 units per 90 days be established for Actiq, based on the daily maximum of four per day recommended in product labeling.

B. RIZATRIPTAN (MAXALT, MAXALT MLT) – The current quantity limit for rizatriptan tablets and orally disintegrating tablets (Maxalt, Maxalt MLT) is 12 tablets per 30 days, or 36 tablets per 90 days. Based on safety recommendations in product labeling, the safety of treating more than four migraine attacks in a 30-day period has not been established. Doses may be repeated after two hours if the first dose is ineffective, with no more than 30 mg taken in any 24-hour period. Based on this, a quantity limit of 12 tablets per 30 days would allow use up to the recommended maximum, assuming that 10-mg tablets are prescribed. However, rizatriptan packaging has been changed to packages of nine rather than six tablets.

The Committee voted (15 for, 0 opposed, 0 abstained, 3 absent) to recommend that the quantity unit for rizatriptan tablets and orally disintegrating tablets be increased to 18 tablets per 30 days, 36 tablets per 90 days, based on the following reasoning:

- A substantial number of patients currently fill prescriptions at the maximum quantity limit of 12 tablets per 30 days.
- The proposed quantity limit allows for dispensing of whole packages of rizatriptan tablets.
- Although the proposed quantity limit does violate the usual rule-of-thumb that 90-day limits will be three times 30-day limits, it is technically feasible to implement and avoids increasing the 90-day to 54 tablets, which is in excess of safety recommendations and not consistent with quantity limits for other triptans.

COMMITTEE ACTION: The Committee voted (15 for, 0 opposed, 0 abstained, 3 absent) to recommend changing the quantity limit for rizatriptan tablets and orally disintegrating tablets (Maxalt, Maxalt MLT) to 18 tablets per 30 days, or 36 tablets per 90 days.

7. ANTIEMETIC DRUG CLASS REVIEW

A. Antiemetic Relative Clinical Effectiveness: The P&T Committee evaluated the relative clinical effectiveness of the antiemetic agents marketed in the United States. The drugs in the class were broken into two subclasses, the newer and older antiemetics. The newer agents include the type 3 serotonin receptor (5-HT3) antagonists ondansetron (Zofran), granisetron (Kytril), and dolasetron (Anzemet); and the neurokinin-1 (NK-1) receptor antagonist aprepitant (Emend). The older antiemetic subclass is comprised of the cannabinoid dronabinol (Marinol); the phenothiazines prochlorperazine and thiethylperazine (Torecan); the antihistamines meclizine and promethazine; and the anticholinergics transdermal scopolamine (Transderm Scop) and trimethobenzamide. The clinical review included, but was not limited to, the requirements stated in the UF Rule. The newer and older antiemetics together account for approximately $37.4 million dollars annually, and are ranked 48th in Military Health System (MHS) drug class expenditures.

1) Newer Antiemetics

A. Efficacy

Efficacy Measure – The Committee evaluated efficacy of the newer antiemetics in chemotherapy induced nausea and vomiting (CINV), radiation induced nausea and vomiting (RINV), post-operative nausea and vomiting (PONV) and nausea and vomiting in pregnancy. Complete response was the primary efficacy measure considered. Complete response is a composite outcome of two or more of the following components: no emesis; no nausea; or no need for rescue medication.

When reviewing efficacy trials in nausea and vomiting, direct comparisons of trials is difficult due to large heterogeneity in the trials. Trials conducted in the setting of CINV and RINV are differentiated by the type of chemotherapy administered, emetogenicity potential of the chemotherapy regimen, number of chemotherapy or radiotherapy courses given, and type of malignancy; and show widely varying outcomes. For trials conducted in the setting of PONV, differences in the type of surgical procedure, duration of surgery, and type of anesthesia make direct comparisons difficult.

Chemotherapy-induced nausea and vomiting (CINV)

5-HT3 antagonists – For CINV, there are several head-to-head trials comparing the three 5-HT3 antagonists which overall have shown no differences in efficacy between the intravenous (IV) and oral routes and no consistent differences in efficacy between ondansetron, granisetron and dolasetron. However there is large heterogeneity between the trials.

5-HT3 antagonists – Head-to-head trials and national guidelines: In two head-to-head trials comparing oral 5-HT3 formulations, the complete response rates, as measured by no nausea or emesis or need for rescue therapy, were similar between granisetron and ondansetron (47% vs. 48%), and dolasetron and ondansetron (76% vs. 72%). There were no trials comparing oral dolasetron with oral granisetron, but a trial comparing IV formulations of these two drugs reported no differences in efficacy. Clinical practice guidelines from four national professional groups consider the 5-HT3 antagonists therapeutically interchangeable for CINV.

Aprepitant – The NK-1 receptor antagonist aprepitant is approved for preventing nausea and vomiting associated with highly emetogenic chemotherapy regimens, including high dose cisplatin. Aprepitant has been evaluated in four active-controlled trials in patients undergoing highly emetogenic chemotherapy regimens. When aprepitant was used as adjunctive therapy to 5-HT3 antagonists plus dexamethasone and older antiemetics, a significantly higher percentage of patients achieved complete response rates, vs. placebo.

Radiation-induced nausea and vomiting (RINV)

Systematic Reviews – Systematic reviews state that the evidence shows no consistent differences in efficacy for ondansetron, granisetron and dolasetron for RINV.

Head-to-head trials and national guidelines – There are no head-to-head trials comparing the 5-HT3 antagonists for RINV. One indirect comparison of ondansetron 8 mg and granisetron 2 mg with a historical control group in the prevention of RINV found no differences between the two 5-HT3 antagonists in achieving complete control of emesis (27% with ondansetron vs. 28% with granisetron vs. 0% in the historical control group). There are no published studies evaluating aprepitant for RINV. Clinical practice guidelines from four national professional organizations state that the three 5-HT3 antagonists are therapeutically interchangeable as first-line prophylaxis for RINV.

Post-operative nausea and vomiting (PONV)

Prevention of PON – The majority of studies evaluating prevention of PONV used intravenous (IV) therapies, and rarely continued oral medication after hospital discharge. There are seven head-to-head trials comparing the efficacy of IV formulations of the 5-HT3 antagonists for prevention of PONV; five trials comparing dolasetron with ondansetron, and two trials comparing granisetron with ondansetron. Although the heterogeneity between the trials was large, overall the complete response rates were similar between ondansetron, granisetron and dolasetron. There are no head-to-head trials of oral formulations of the 5-HT3 antagonists for prevention of PONV. A systematic review of four placebo-controlled trials comparing either oral or IV 5-HT3 formulations allowed indirect comparisons between oral dolasetron, IV dolasetron, and IV granisetron. The complete response rates were similar between drugs.

Treatment of PONV – Treatment of PONV most commonly occurs with IV therapy, and is of minor importance to this review. There are no head-to-head trials comparing efficacy of the 5-HT3 antagonists for treatment of PONV. Three systematic reviews of active and placebo controlled trials of the 5-HT3 antagonists in the treatment of PONV provided numbers needed

to treat (NNT) to obtain complete control of further nausea and vomiting (complete response). In one review, no statistically significant differences were found between dolasetron and ondansetron in treating PONV occurring within 6 hours of surgery (NNT of 2.0-3.5 with ondansetron vs. 4.2-6.1 with dolasetron). In the same review there were no significant differences between granisetron and ondansetron in treating PONV occurring < 24 hours after surgery (NNT of 3.3-6.3 with ondansetron vs. 2.4-3.3 with granisetron). The NNTs from all three reviews were similar for ondansetron, granisetron, and dolasetron. There are no published studies evaluating aprepitant for PONV.

Nausea and vomiting in pregnancy

Systematic reviews and MHS utilization – No newer antiemetics are FDA-approved for treating nausea and vomiting in pregnancy. An evidenced-based review concluded that there is insufficient data to recommend use of ondansetron as a first-line agent for this indication. A database linking prescription data with diagnosis codes shows that 21% ondansetron usage in the MHS is for nausea and vomiting in pregnancy.

Clinical trials and case reports – One trial compared IV ondansetron 10 mg with IV promethazine 50 mg in 30 women hospitalized with hyperemesis gravidarum. No differences were found in any outcome measure. One published case report showed that ondansetron 8 mg IV given twice daily was effective at reducing emesis, and that ondansetron 4 mg orally given three times daily for 25 weeks was also effective.

National guidelines – Guidelines from the American College of Obstetricians and Gynecologists (ACOG) state that ondansetron may be used IV as third line therapy if dehydration is present, and IV fluid replacement and dimenhydrinate, metoclopramide, or promethazine have failed to control symptoms. The 5-HT3 antagonists and aprepitant are rated as pregnancy category B by the FDA.

B) Safety / Tolerability

Major adverse events – Ondansetron, granisetron and dolasetron all carry a class warning regarding potential prolongation of the QTc interval. The risk is dose dependent. All three 5-HT3 antagonists can rarely cause anaphylaxis; ondansetron and granisetron can rarely cause bronchospasm. Aprepitant has rarely been associated with Stevens-Johnson Syndrome and angioedema.

Minor Adverse events – For the newer antiemetics, the most commonly reported adverse effect is headache, occurring in 8-18% of patients. Asthenia/fatigue, constipation, and increases in liver enzymes also occur with an incidence of greater than 5%. Aprepitant is associated with diarrhea, dizziness, hiccups and increases in liver enzymes, all occurring in <6% of patients. No dosage adjustments are necessary for the four newer antiemetics in patients with renal dysfunction. The maximal dose of ondansetron should be limited to 8 mg in patients with severe hepatic dysfunction.

Drug Interactions – All three 5-HT3 antagonists are metabolized by varying degrees through the Cytochrome P450 (CYP450) enzyme system. The 5-HT3 antagonists are metabolized by multiple pathways within the system. Ondansetron is metabolized to the greatest extent, followed by dolasetron and granisetron; however, there are no requirements for ondansetron dosage adjustments when given with CYP450 inducers. Aprepitant can inhibit Cytochrome P450 3A4 (CYP3A4) enzymes, and is associated with the most clinically important drug interactions of the newer antiemetics. Aprepitant increases concentrations of dexamethasone up

to two and half times, and if administered concomitantly with dexamethasone, the dexamethasone dose should be reduced by 50%.

C) Other Factors

Available formulations – Ondansetron is available in several oral formulations, including an oral tablet, oral solution, and orally dissolving tablet (ODT). Ondansetron ODT may be swallowed without the need to consume additional liquid that could trigger vomiting; however, it should be used with caution in patients with phenylketonuria, as it contains aspartame. Granisetron is available in an oral tablet and oral solution.

Pediatrics – Ondansetron and dolasetron are approved for prevention of CINV in pediatrics. Ondansetron is approved for use in children as young as four years of age, while dolasetron is approved for use in children as young as two years. The oral formulation of granisetron is not approved for use in children; however the IV formulation is approved for use in children older than two years. Aprepitant is not approved for use in the pediatric population.

*FDA indicatio*ns – Of the newer antiemetics, ondansetron has the most FDA-approvals (CINV, RINV, and PONV). Granisetron is approved for CINV and RINV, and dolasetron is approved for CINV and PONV. Aprepitant is approved for prevention of CINV caused by moderately or highly emetogenic chemotherapy regimens.

Quantity Limits – There are existing quantity limits in place for the four newer antiemetics, which take into account FDA-approved indications and dosing recommendations for CINV, RINV, and PONV. Quantity limits may be overridden for individual patients if greater quantities are determined to be medically necessary. A frequent reason for medical necessity is severe nausea and vomiting associated with pregnancy (i.e., hyperemesis gravidarum).

MHS Utilization – The most widely prescribed newer antiemetic in the MHS is ondansetron, with 3,500 prescriptions per month. Over 51% of the MHS usage of the newer antiemetics is for CINV; nausea and vomiting in pregnancy accounts for 15% of the usage of the newer antiemetics, RINV comprises 10% of usage, PONV 2% of usage, and other diagnoses 22% of usage.

Provider Survey – Overall, providers preferred ondansetron, primarily due to more familiarity over the other 5-HT3 antagonists. Several providers commented that they preferred the newer antiemetics over the older antiemetics due to less sedation, which is particularly beneficial for active duty members or those with childcare responsibilities.

Conclusion for the newer antiemetics – The committee concluded that there is insufficient evidence to suggest that the antiemetic effects of the 5-HT3 antagonists differ significantly between drugs. Ondansetron, granisetron and dolasetron show efficacy for CINV, RINV, and PONV. Ondansetron shows efficacy for treating nausea and vomiting in pregnancy, but should be used third line. Aprepitant has shown efficacy in placebo controlled trials for CINV when used as an adjunct to 5-HT3 antagonists for patients undergoing highly emetogenic chemotherapy regimens. The adverse effect profiles of 5-HT3 antagonists and aprepitant are similar in nature. Ondansetron has the largest number of oral formulations, and is approved for use in pediatrics, along with dolasetron.

2) Older Antiemetics

A) Place in therapy and national guidelines – The older antiemetics are still widely used to treat nausea, vomiting and motion sickness. Many of the older antiemetics are mentioned in national guidelines for the treatment of CINV and PONV, and are commonly used in these

settings. Prochlorperazine is used for indications other than nausea and vomiting, including for anxiety and schizophrenia. Promethazine is a second-line therapy for treatment of nausea and vomiting in pregnancy, according to ACOG guidelines. Dronabinol is commonly employed in the treatment of glaucoma, AIDS, chemotherapy-related anorexia and spasticity associated with multiple sclerosis.

B) Adverse effects – All the older antiemetics are associated with drowsiness, dizziness and somnolence. The phenothiazines (prochlorperazine, thiethylperazine) and antihistamines (meclizine, promethazine) can cause rare but serious adverse events including neuroleptic malignant syndrome, reversible dystonic reactions, seizures, irreversible tardive dyskinesias, agranulocytosis and severe leukopenia. Common adverse effects of the anticholinergic agents (trimethobenzamide, scopolamine) include dry mouth and eyes, and urinary retention in elderly patients. Confusion, distorted perception, and rare hallucinations and severe paranoia have been linked to dronabinol.

C) Other factors – Four of the older antiemetics are available in generic formulations; meclizine, promethazine, prochlorperazine, and trimethobenzamide. The older antiemetics are available in various dosage forms that are advantageous for use as rescue therapy in nausea and vomiting when the oral route can not be used. Prochlorperazine, promethazine and trimethobenzamide are available in suppository form. Transdermal scopolamine patches offer a topical route, but should not be used for acute nausea and vomiting, due to delayed absorption. With the exception of meclizine, which has a pregnancy category B rating, all of the older agents are ranked pregnancy category C by the FDA. The older antiemetics are indicated for use in children, with the exception of thiethylperazine. The package insert for promethazine has a black box warning regarding use in children under the age of two due to respiratory depression. Dronabinol is a Drug Enforcement Administration (DEA) controlled schedule III substance. The most widely prescribed older antiemetic in the MHS is promethazine, with 40,000 prescriptions per month.

*Conclusions for the older antiemetic*s – The older antiemetics are frequently used for nausea and vomiting, and several are used for indications other than emesis. The availability of non-oral dosage formulations is useful for rescue therapy of nausea and vomiting. Thiethylperazine is the only older antiemetic not approved for pediatric use, although promethazine should be used with caution in children due to possible respiratory depression. All the older agents can cause sedation and dizziness.

Overall clinical effectiveness conclusion – The Committee concluded: (1) the 5-HT3 antagonists ondansetron, granisetron and dolasetron have shown similar complete response rates in patients with CINV, RINV, and PONV; (2) the NK-1 receptor antagonist aprepitant serves a unique role in preventing CINV caused by highly emetogenic chemotherapy regimens and is required for clinical coverage; (3) for nausea and vomiting in pregnancy, ondansetron should be reserved for use as third-line therapy in pregnant women requiring IV hydration who have not responded to other therapies; (4) there is insufficient evidence to suggest that there are major differences in the adverse effect profiles of the 5-HT3 antagonists or aprepitant; headache and gastrointestinal effects are the most commonly reported adverse events; (5) aprepitant is the newer antiemetic that has the most clinically important drug interaction profile, due to its metabolism via the CYP3A4 enzyme system; (6) there are differences among the newer antiemetics in terms of availability of oral formulations, approval for use in children, and number of FDA-approved indications; (7) none of the newer antiemetics is sufficiently less clinically effective than the others to be classified as non-formulary, based on clinical issues

alone; and (8) none of the older antiemetics has a significant, clinically meaningful therapeutic disadvantage in terms of safety, effectiveness, or clinical outcome compared to the other agents to warrant classification as non-formulary, based on clinical issues alone.

COMMITTEE ACTION: The Committee voted (16 for, 0 opposed, 0 abstained, 2 absent) to accept the clinical effectiveness conclusions stated above.

B. Antiemetic Relative Cost Effectiveness: In considering the relative cost-effectiveness of pharmaceutical agents in this class, the P&T Committee evaluated the costs of the agents in relation to the efficacy, safety, tolerability, and clinical outcomes of the other agents in the class. Information considered by the P&T Committee included but was not limited to sources of information listed in 32 C.F.R. 199.21(e)(2). Three separate pharmacoeconomic analyses were performed: a cost-minimization analysis (CMA) on the newer 5-HT3 antiemetics subclass, followed by a budget impact analysis (BIA); a cost-effectiveness analysis (CEA) of aprepitant to evaluate its place in therapy; and lastly a cost-analysis on the older antiemetic subclass.

Given the evidenced-based relative clinical effectiveness evaluation conclusion that there was insufficient evidence to suggest that the 5-HT3 antagonists differed in regards to efficacy, safety, tolerability, and clinical outcomes in the treatment of CINV, RINV, and PONV, a CMAwas performed to determine the relative cost-effectiveness of the agents within the 5-HT3 subclass. The cost examined was the total weighted average cost per treatment episode across all points of service. Results of the analysis for the newer antiemetic drugs (5HT-3s) showed granisetron was the most cost effective 5HT-3 antiemetic agent with the lowest average cost per treatment episode across the MHS.

The results of the above analysis were then incorporated into a BIA. A BIA accounts for other factors and costs associated with a potential decision to recommend that one or more agents be classified as non-formulary, such as market share migration, cost reduction associated with non-formulary cost shares, and medical necessity processing fees. The goal of the BIA was to assist the Committee in determining which group of 5-HT3 antagonists best meet the majority of the clinical needs of the DoD population at the lowest cost to the MHS. Based on the results of the BIA and other clinical and cost considerations (ondansetron is projected to undergo generic competition in 2006), the Committee agreed that a group of 5-HT3 antagonists that included granisetron and ondansetron best achieved this goal when compared to other combination groups of 5-HT3 antagonists, and thus were determined to be more cost-effective relative to other combination groups.

A CEA was also conducted to evaluate the place in therapy for aprepitant, a NK-1 antagonist. Aprepitant is indicated for adjunctive therapy along with other antiemetics for delayed nausea and vomiting associated with chemotherapy. The results of the CEA showed that: 1) the blanket purchase agreement (BPA) offered price for aprepitant improved its cost-effectiveness over baseline, and 2) when total health care costs are considered, aprepitant is cost-effective as an adjunct in the treatment of chemotherapy induced nausea and vomiting.

Finally, a cost analysis for the older antiemetics (promethazine, prochlorperazine, trimethobenzamide, thiethylperazine, meclizine, scopolamine, and dronabinol) was presented. The results of the cost-analysis showed that the cost associated with these agents is about 25% of the overall anti-emetic drug spend. However, 72% of the costs for these older anti-emetic

drugs were generated in the retail setting. Over half of this figure was for promethazine, which is available in generic form. The conclusion of the cost analysis was that no savings would be achieved by placing any of the older antiemetics in the non-formulary tier of the UF.

Conclusion: The P&T Committee, based upon its collective professional judgment, voted (16 for, 0 opposed, 0 abstained, 2 absent) to accept the antiemetic pharmacoeconomic analyses presented by the PEC. The Committee concluded that granisetron and ondansetron are the more cost effective 5HT-3 antiemetic drugs; that dolasetron is not cost-effective relative to the other 5-HT3 antagonists, that it is cost-effective for aprepitant to be used as an adjunct for the treatment of CINV; and that the older antiemetics are all relatively cost-effective.

The P&T Committee also recommended that the current quantity limits for the newer antiemetics should remain unchanged. They agreed, however, that a more systematic set of criteria addressing severe nausea and vomiting associated with pregnancy should be developed. Such criteria would be particularly beneficial for MTFs.

COMMITTEE ACTION: Taking into consideration the conclusions from the relative clinical effectiveness and the relative cost effectiveness determinations for the anti-emetic drugs, and other relevant factors, the P&T Committee, based upon its collective professional judgment, voted (14 for, 1 opposed, 1 abstained, 2 absent) to recommend that dolasetron be classified as non-formulary under the UF, with granisetron, ondansetron, aprepitant, dronabinol, meclizine, prochlorperazine, promethazine, scopolamine, thiethylperazine, and trimethobenzamide remaining on the UF.

C. Antiemetic Medical Necessity Criteria: Based on the clinical evaluation of the antiemetics, and the conditions for establishing medical necessity for a non-formulary medication provided for in the UF rule, the P&T Committee recommended the following medical necessity criteria for dolasetron.

1) Use of formulary antiemetics is contraindicated, and dolasetron is not contraindicated.
2) The patient has experienced significant adverse effects from the formulary antiemetics, or is likely to experience significant adverse effects from formulary antiemetics, and the patient is expected to tolerate dolasetron.
3) Treatment with formulary antiemetics has resulted in therapeutic failure, and the patient is expected to respond to dolasetron.

Because of the clinical differences between antiemetics, the Committee agreed that the most appropriate formulary alternatives for dolasetron are the other 5-HT3 antagonists.

COMMITTEE ACTION: The P&T Committee voted (15 for, 0 opposed, 1 abstained, 2 absent) to approve the anti-emetic medical necessity criteria.

D. Antiemetic UF Implementation Period: The P&T Committee recommended an effective date no later than the first Wednesday following a 60 day implementation period. The implementation period will begin immediately following approval by the Director, TMA.

MTFs will not be allowed to have dolasetron on their local formularies. MTFs will be able to fill non-formulary requests for dolasetron only if both of the following conditions are met: 1) the prescription is written by an MTF provider, and 2) medical necessity is established. MTFs

may (but are not required to) fill a prescription for dolasetron written by a non-MTF provider to whom the patient was referred, as long as medical necessity has been established.

COMMITTEE ACTION: The P&T Committee voted (14 for, 1 opposed, 1 abstained, 2 absent) for an effective date no later than the first Wednesday following a 60 day implementation period. The implementation period will begin immediately following approval by the Director, TMA.

E. Antiemetics BCF Review and Recommendations: The P&T Committee had previously determined that zero to one newer antiemetics and at least one older antiemetic should be added to the BCF, based on clinical and cost effectiveness review. As a result of the clinical and economic evaluations presented, the P&T Committee recommended that promethazine be maintained on the BCF.

COMMITTEE ACTION: The P&T Committee voted (15 for, 0 opposed, 1 abstained, 2 absent) to maintain oral and rectal promethazine on the BCF.

8. CONTRACEPTIVE AGENTS DRUG CLASS REVIEW

A. Contraceptive Relative Clinical Effectiveness Review: The P&T Committee evaluated the relative clinical effectiveness of the oral, transdermal, injectable, and vaginal ring contraceptives available in the U.S. Contraceptive products were divided into the subgroups outlined in Table 1, based on estrogen content, phasic formulation, and route of administration.

Table 1: Oral, Transdermal Patch, Vaginal Ring, and Injectable Contraceptive Products Available in the U.S.

Emergency Contraceptives	0.75 mg levonorgestrel	Plan B	Duramed/Barr	4,049

Oral contraceptives (OCs) differ from most other drug classes in two regards: 1) unique combinations of varying strengths of specific estrogen and progestogen components are considered to be separate products (e.g., Ortho-Novum 1/35 and Ortho-Novum 1/50) rather than different strengths of the same product; and 2) generic versions of branded contraceptive products typically have brand names of their own. Other factors (such as FDA-approved special packaging/labeling or the content of "placebo" tablets) may also affect generic equivalency. For the purpose of making formulary recommendations, the P&T Committee made its selections at the "generic product" level as outlined in Table 1, consistent with its actions in other drug classes. For example, ethinyl estradiol 35 mcg; 1.0 mg norethindrone constituted a single line item to be considered for placement on the UF. Specific originator products (e.g., Ortho-Novum 1/35) and generic equivalents (Necon, Norinyl, and Nortrel) were not considered individually.

The clinical review included consideration of pertinent information from a variety of sources determined by the P&T Committee to be relevant and reliable, including but not limited to sources of information listed in 32 CFR 199.21(e)(1). The P&T Committee was advised that there is a statutory presumption that pharmaceutical agents in a therapeutic class are clinically effective and should be included on the UF, unless the P&T Committee finds by a majority vote that a pharmaceutical agent does not have a significant, clinically meaningful therapeutic advantage in terms of safety, effectiveness, or clinical outcome over the other pharmaceutical agents included on the UF in that therapeutic class.

During a twelve-month period ending 31 Jan 2006, 552,272 MHS beneficiaries received one or more contraceptive prescriptions, accounting for about $80 million in annual expenditures across the MHS.

1) DoD Provider Input

A total of 79 survey responses were received from providers in time to be tabulated for P&T Committee review. Responders were family practice physicians (26), women's health nurse practitioners (21), obstetricians /gynecologists (18), family nurse practitioners (6), certified nurse-midwives (4), or other providers (4). A number of responses, including some from internal medicine physicians, were received too late for tabulation, but were not qualitatively different from other providers' responses.

2) Potential Differences between Contraceptive Products

There are a wide variety of contraceptive products. Points of difference include estrogen content; progestogen content; regimen (e.g., extended use, 24-day cycle products); phasic formulation; proven or potential usefulness for other conditions in addition to contraception (e.g., acne); and route of administration. Most OCs contain both an estrogen and a progestogen component. Progestogen-only OCs are used much less commonly than combined OCs, but fill a distinct clinical niche for women who should not receive estrogen.

Estrogen content – The estrogen component in almost all combined contraceptives is ethinyl estradiol; mestranol (a prodrug of ethinyl estradiol) is used in a few older products. The amount of ethinyl estradiol included in specific products varies from as little as 15-20 mcg per day to as much as 50 mcg per day in older products. Low-estrogen products (20-30 mcg of ethinyl estradiol) are most commonly used. The availability of a wide array of contraceptive products with differing ethinyl estradiol levels is necessary because of the need to maintain contraceptive effectiveness and control irregular bleeding (cycle control) while minimizing common adverse effects and thromboembolic risk. Considerable intra- and inter-patient variability in estrogen metabolism contributes to the need for multiple products. Another contributing factor may be the fact that adverse effects and cycle control problems with all contraceptive products tend to occur more frequently in the first few cycles after initiation of treatment; switching products prematurely may lead women to falsely believe that they cannot tolerate specific products.

Progestogen content – Contraceptive products available in the U.S. include a variety of progestogens. Based on chemical structure, a recent Cochrane review (Maitra et al, 2005) classified progestogens (not including non-U.S. products) as follows:

- First generation: norethindrone, ethynodiol diacetate
- Second generation: levonorgestrel, norgestrel
- Third generation: desogestrel, norgestimate (some authors classify norgestimate as second generation, since it is partially metabolized to levonorgestrel)
- Unclassified: drospirenone

The injectable contraceptives (Depo-Provera and generics, Depo-subq Provera 104) contain depot medroxyprogesterone acetate (DMPA), a derivative of progesterone.

Regimen – While most combined contraceptives—including the transdermal patch and vaginal ring—are based on a 21-day "on", 7-day "off" cycle, this regimen is often modified in clinical practice by either extending the active treatment period and/or shortening the medication-free period. Extended treatment cycles or continuous (daily) use of combined OCs have been used

clinically for many years to treat menstrual migraines, dysmenorrhea, endometriosis, and other conditions associated with menses. Over time, extended or continuous use of OCs for practical or convenience reasons (reducing or eliminating menstrual periods) has come into more common use. A Cochrane review [Edelman et al, 2005] concluded that extended or continuous use of contraceptives was reasonable for women without contraindications, based on the results of six trials. A single contraceptive product, Seasonale, is labeled and specially packaged for extended cycle use (84 days on, 7 days off), although any monophasic OC could be used for extended or continuous treatment by eliminating unneeded placebo tablets.

A majority of DoD providers surveyed indicated that extended or continuous cycle offered advantages over conventional dosing, with 29 citing convenience/lifestyle advantages, and 36 citing advantages in treating menstrual-related problems. A total of 43 providers (out of 62 commenting) did not agree that Seasonale provided a benefit relative to another OC given on the same dosing schedule (84 days on, 7 days off); 19 commented on the greater convenience of packaging. Many providers without experience with Seasonale reported using other OCs on an extended-cycle basis.

Two newly approved low-estrogen contraceptive products, Loestrin 24 Fe and Yaz, are labeled for use as a 24-day on, 4-day off regimen. The shortened "off" cycle is intended to decrease adverse effects associated with hormone withdrawal. It may also provide a greater safety margin for contraceptive effectiveness by decreasing the likelihood of follicle development during the "off" cycle.

Phasic formulations – Biphasic and triphasic oral contraceptives attempt to "mimic" changes in levels of estrogen and progesterone seen during the normal menstrual cycle, in an attempt to decrease adverse effects by decreasing hormonal steroid exposure. The introduction of these products was probably primarily a reaction to the controversy about the relationship between thromboembolic events and progestogen content, since lower total amounts of progestogens can be achieved by providing a varying amount throughout the cycle. The biphasic OCs initially introduced to the market were rapidly superseded by triphasic OCs, resulting in infrequent use of the older biphasic products. Triphasic products, which vary doses of progestogen and/or estrogen three times during the treatment period, remain popular.

Although classified as a biphasic product, Mircette and its generic equivalents (21 days of EE 20 mcg/desogestrel 150 mcg followed by 2 days of placebo and 5 days of 10 mcg EE) are more similar to a low-estrogen monophasic product plus supplemental estrogen than to the older biphasic products. Mircette may be useful in perimenopausal women due to the more constant estrogen levels.

Usefulness for other conditions – Most if not all combined contraceptives offer non-contraceptive benefits, including control of heavy menstrual bleeding or irregular cycles, reduction of acne and dysmenorrhea, and favorable effects on other conditions, such as endometriosis pain and menstrual migraines. Relatively few contraceptive products have FDA-approved indications in addition to prevention of pregnancy. However, given the lack of substantial differences between products with regard to contraceptive effectiveness, the choice of a specific contraceptive product may depend on its proven or potential usefulness for another condition.

Alternative routes of administration – Contraceptive products offering alternative routes of administration include DMPA injections, a transdermal patch (Ortho Evra), and a vaginal ring (Nuvaring). Two DMPA formulations are available: 150 mcg, given by deep intramuscular (IM) injection (Depo-Provera, generics), and 104 mcg (Depo-subq Provera 104), given by

subcutaneous (SC) injection (less painful and may allow patient self-administration). DMPA injections are given every 11 to 13 weeks. In addition to prevention of pregnancy, the 104 mcg formulation is also approved by the FDA for endometriosis pain. The transdermal patch is applied weekly for three weeks, followed by a patch-free week, while the vaginal ring is inserted on a monthly basis and then removed after 3 weeks, followed by a 7-day ring-free period.

Emergency contraception – The only product currently labeled as emergency contraception is levonorgestrel 0.75 mg (Plan B), which is given as one dose (1 tablet) within 72 hours after unprotected intercourse and a second dose 12 hours later. A combination emergency contraception product (Preven) was discontinued in 2004. In addition to Plan B, the FDA has declared several brands of combined OCs to be safe and effective for emergency contraception, including Ovral, Alesse, Nordette or Levlen, Lo/Ovral, Triphasil or Tri-Levlen. Progestogen-only regimens such as Plan B have been shown to be more effective and better tolerated for emergency contraception than combination OCs.

3) Efficacy / Effectiveness

Contraceptive effectiveness – All of the reviewed contraceptives are highly effective at preventing pregnancy when used correctly. Progestogen-only OCs may be slightly less effective than combined OCs and for that reason have stricter use requirements (i.e., they must be taken at the same time each day, without an "off" period). There is some question as to whether the lowering of estrogen content in combined OCs over time has resulted in a decrease in contraceptive effectiveness, although data are lacking. Methods that reduce the potential for user error (e.g., injectable contraceptives) are known to decrease "actual use" failure rates. Whether or not potentially improved compliance related to less-frequent dosing of the transdermal patch and vaginal ring results in decreases in "actual use" failure rates remains to be seen; contraceptive effectiveness so far appears similar to combined OCs. Drug interactions and patient weight may also affect contraceptive effectiveness.

Overall, the differences in contraceptive effectiveness among the reviewed contraceptive products appear minor, with no reliable evidence to suggest substantial differences in contraceptive effectiveness based on progestogen content, phasic formulation, or regimen.

Efficacy in treating other conditions

Acne – All combined contraceptives are likely to have beneficial effects on acne, based on several potential mechanisms, including decreased production and increased binding of free testosterone, blocking androgen receptors, and inhibiting conversion of testosterone to dihydrotestosterone in the hair follicles and skin. Clinically, progestogens with relatively low binding to androgen receptors have been preferred for patients with androgenic adverse effects (such as acne or hirsutism), although actual differences between products are unclear. A 2005 Cochrane review [Arowojolu et al] reviewed 14 head-to-head contraceptive trials (9 different comparisons) focusing on acne; unfortunately, most products included in the review are not currently available in the U.S. The three trials remaining either reported no difference between products or inconclusive results.

Contraceptive products with an additional FDA approved indication for acne include Ortho Tri-Cyclen (a triphasic product containing 35 mcg EE and varying amounts of norgestimate, which is now generically available) and Estrostep Fe (a triphasic product containing varying amounts of estrogen and 1 mg norethindrone). Trials with products containing drosperinone, which has anti-androgen properties, have reported comparable to somewhat superior results

compared to a product containing cyproterone (a progestogen traditionally favored in the United Kingdom for acne treatment, but not available in the U.S.) [Van Vloten et al, 2002] and Ortho Tri-Cyclen [Thorneycroft et al, 2004].

The vast majority of DoD providers surveyed (76/79) agree that other OCs work as well for acne as Ortho Tri-Cyclen, despite its FDA indication.

Premenstrual Syndrome (PMS) / Premenstrual Dysphoric Disorder (PMDD) – Continuous use of OCs may decrease premenstrual symptoms. Several clinical trials with drospirenone-containing OCs have reported favorable effects on PMDD, a severe form of PMS, especially with regard to fluid retention and weight fluctuations ("bloating").

Endometriosis pain – OCs with higher progestational activity and/or continuous use of contraceptives may be preferred in patients with endometriosis pain, which is related to the menstrual cycle. Progestogen-only DMPA injections are associated with improvements in endometriosis; the subcutaneous administered 104 mg strength (Depo-subq Provera 104) has an FDA-approved indication for endometriosis pain.

Heavy menstrual bleeding and dysmenorrhea (menstrual pain) – Combined OCs have been used to treat dysmenorrhea (by decreasing prostaglandins and thus uterine motility/cramping) and heavy menstrual bleeding (by promoting regular shedding of a thinner endometrial lining) since their introduction in 1960. While clinical evidence supports efficacy, most of the literature addresses the older products (≥ 50 mcg EE) and does not support conclusions about the efficacy or comparative efficacy of currently used low estrogen products.

4) Safety and Tolerability

Serious adverse events/contraindications – Use of combined OCs is associated with increased risk of several serious conditions, including myocardial infarction, thromboembolism, stroke, hepatic neoplasia, and gallbladder disease, although the absolute risk of these events is very low in women without additional risk factors. Much of the available epidemiological data was obtained from studies using higher estrogen and progestogen doses than those currently in use; the effect of long-term, low-estrogen OC use has yet to be determined. Risks associated with the patch and vaginal ring are largely unknown, although they are presumed to be similar to those of combined OCs.

Use of combined OCs is associated with an increased risk of venous thromboembolism (VTE) (e.g., deep vein thrombosis, pulmonary embolism). Most data relate to products with higher doses of estrogen than are currently used; low estrogen products may be associated with a lower risk. The issue of whether third-generation progestogens (e.g., desogestrel) are associated with an increased thromboembolic risk compared to second-generation progestogens has been controversial; however, many sources now appear to agree that there is a modestly increased risk with products containing desogestrel, compared to those containing levonorgestrel. The risk of VTE with norgestimate appears similar to levonorgestrel and lower than desogestrel, based on limited data [Gomes et al, 2004]. Epidemiological data for drospirenone is not yet available. A 2004 safety review reporting 3-year interim results from a large, controlled, postmarketing surveillance study [Heinemann & Dinger, 2004] did not suggest an excess risk with drospirenone-containing products compared to those containing levonorgestrel or other progestogens.

An increased risk of myocardial infarction (MI) and stroke has been associated with OC use, primarily in smokers or women with underlying risk factors for coronary artery disease. Most data relate to products with higher doses of estrogen than are currently used; low estrogen

products may be associated with lower risk. Whether progestogen content affects the risk of MI or stroke is unclear.

Absolute contraindications to the use of combined contraceptives include: previous thromboembolic event or stroke, cerebral vascular or coronary artery disease, or valvular heart disease with complications; severe hypertension; headaches with focal neurologic symptoms; known or suspected estrogen-dependent tumor (e.g., endometrial, breast cancer); liver disease; cholestatic jaundice of pregnancy or jaundice with prior hormonal contraceptive use; major surgery with prolonged immobilization; pregnancy; undiagnosed abnormal uterine bleeding; and women over age 35 years who smoke.

Common adverse effects – In general, adverse effects of oral, transdermal, or vaginal ring contraceptives may include: breast tenderness, headache, migraine, nausea, nervousness, vomiting, dizziness, weight gain, fluid retention, tiredness, decline of libido, and increased blood pressure.

Estrogen content and adverse effects – Logically, lower estrogen products (e.g., ≤ 20 mcg EE) are associated with a lower risk of estrogen-related adverse effects and a lower risk of thromboembolic events (although data are limited). However, this must be balanced against a greater vulnerability to compromises in contraceptive effectiveness due to missed doses or drug interactions, a potential decrease in non-contraceptive benefits (e.g., reduction in risk of ovarian cancer or protection against functional ovarian cysts), and a higher incidence of cycle control problems (e.g., breakthrough bleeding and spotting). Determination of the "best" estrogen dose – reliable pregnancy prevention with acceptable cycle control and minimal adverse effects – is complicated by wide inter-patient variability in hormonal blood levels.

Progestogen content and adverse effects – There is considerable difference of opinion among providers concerning the extent to which the choice of progestogen affects tolerability. Products containing third-generation progestogens appear to have fewer androgenic effects than the first- and second-generation products, and may be favored in patients with androgenic adverse effects such as acne or hirsutism (although all combined OCs reduce free testosterone levels and therefore tend to have favorable effects on acne). According to a Cochrane review last updated in 2005 (Maitra et al), second- and third-generation products may offer some advantage over first generation products with respect to cycle control (e.g., minimizing spotting or breakthrough bleeding). The magnitude of the difference is unclear.

Drospirenone is a derivative of spironolactone with anti-mineralocorticoid and anti-androgenic properties similar to progesterone. In addition to progesterone receptors, drospirenone binds to aldosterone receptors in the kidney; the effect is similar to 25 mg of spironolactone. As a consequence, drospirenone reduces fluid retention and weight fluctuations ("bloating"). It may cause concerns about hyperkalemia in patients with a predisposing condition or on other medications that increase potassium levels (women receiving daily, long-term treatment with medications that can increase potassium should have their serum potassium levels checked during the first treatment cycle). While precautions are indicated, there appears to be little evidence to cause serious concern. About 14 million women worldwide have received drospirenone-containing products, according to the manufacturer.

Adverse effects with the transdermal patch – Based on a comparative trial, adverse effects of the transdermal patch appear similar to a combined OC comparator, with the exception of a higher incidence of site reactions, breast symptoms (e.g., breast tenderness), and dysmenorrhea. Another obvious concern with the patch is adhesion; about 5% of patches used during clinical trials had to be replaced, because they fell off or partially detached. A small study cited in

labeling showed a relatively small percentage of patches falling off under conditions of heat, humidity, or exercise; anecdotal reports and survey results from deployment sites suggest a much larger percentage. Site reactions, reported in about 17% of patients, were mostly mild to moderate (92%). Skin pigmentation changes were rarely reported (overall in <1% of patients), with one severe case reported in labeling.

Based on pooled data from North American pivotal trials (Archer et al, 2002), the patch may have compliance advantages compared to combined OCs, with perfect compliance (21 days of drug-taking followed by 7 drug-free days) in 79% of cycles for patients receiving comparator OCs vs. 98% receiving the patch.

DoD providers surveyed cited advantages of the transdermal patch as being improved compliance with infrequent dosing and availability of a different dosing option; disadvantages included the patch coming off, the uncertainty regarding estrogen exposure and VTE risk, the incidence of skin reactions, and weight limitations.

A recent pharmacokinetic study noted that systemic exposure (area under the curve and steady state concentrations) with the patch was about 60% higher than a combined OC with 35 mcg ethinyl estradiol and 0.25 norgestimate, although peak concentrations are about 25% lower. This information, which has been added to product labeling, has caused uncertainty regarding safety of the patch with respect to estrogen content and associated thromboembolic risk. Epidemiological data is limited to one published and one unpublished study, with conflicting results.

Adverse effects with the vaginal ring – Adverse effects with the vaginal ring appear low compared to rates typically reported with combined OCs. Overall, 5-14% of women reported the most common adverse effects (vaginitis, headache, vaginal secretion, weight gain, and nausea). A cross-over study focusing on genital symptoms (Veres et al, 2004) showed a higher percentage of women reporting vaginal wetness during ring use compared to a combined OC (63% vs. 43%), but did not find evidence of any pathological conditions associated with ring use. Specific to the vaginal ring are issues such as interference with intercourse (about 85% of women and 71% of partners say they cannot feel the device during intercourse), premature expulsion (occurring in about 0.5% of cycles), and lack of comfort with inserting and removing the vaginal ring (which does not require exact positioning). After insertion, the product remains effective for about 35 days, providing a safety margin if the patient fails to remove the ring on schedule and making extended or continuous use feasible.

DoD providers surveyed cited advantages of the vaginal ring as being improved compliance with infrequent dosing and a good adverse effect profile; disadvantages included a substantial number of patients who are not comfortable with the method and deployment limitations related to storage requirements.

Adverse effects with DMPA injections – Women receiving injectable DMPA may lose significant bone mineral density, an effect which may not be completely reversible. It is unclear whether use during adolescence or early adulthood reduces peak bone mass and increases the risk of osteoporotic fracture in the future. Injectable DMPA products carry a black box warning advising that it be used as a long-term birth control method (e.g., longer than two years) only if other birth control methods are inadequate.

Of the contraceptives reviewed, only injectable DMPA appears to be associated with progressive (and substantial) weight gain, with labeling for the 150 mg IM strength reporting an average weight gain of 5.4 lb in women completing 1 year of treatment, 8.1 lb after 2 years,

13.8 lb after 4 years, and 16.5 lb after 6 years. Labeling for the 104 mg SQ strength provides one-year results from three large clinical trials (average weight gain 3.5 lbs in the first year of use) and 2-year results from a small study comparing the two strengths (average weight gain of about 7.5 lbs with either strength).

Other issues with DMPA injections include amenorrhea in a high percentage of users (may be an advantage or disadvantage); irregular menses and unpredictable spotting/bleeding in the first several months of use; and lack of immediate reversibility (10 months to return to baseline fertility).

Drug interactions – A large number of medications may interact with hormonal contraceptives. Oral contraceptives may also affect levels of other medications. Data do not suggest a higher incidence of clinically significant drug interactions based on differences in progestogen content, phasic formulation, regimen, or route of administration.

Use in special populations – There are multiple considerations which may affect the choice of contraceptives in women with concomitant conditions (e.g., endometriosis). Progestogen-only OCs may be preferred in women who are breastfeeding, due to concerns about estrogen effects on the content and quality of breast milk, and the potential for infant exposure.

5) Other Factors – One practical concern with the vaginal ring is storage. Refrigeration is required prior to dispensing. After dispensing, the product may remain at controlled room temperature for up to 4 months, but should not be exposed to excessive heat. Heat, humidity, and exercise may also affect adhesion of the transdermal patch.

6) Overall Clinical Effectiveness Conclusion – The P&T Committee concluded that: 1) contraceptives vary in estrogen and progestogen content, regimen (e.g., extended use), phasic formulation, desirability for non-contraceptive uses, and routes of administration; 2) there is wide intra- and inter-patient variability in pharmacokinetics; 3) differences may affect safety, adverse effects/tolerability, convenience/compliance, or effectiveness for non-contraceptive uses; 4) there do not appear to be substantial differences in contraceptive effectiveness across products; 5) providers desire a wide variety of choices based on estrogen and progestogen content consistent with variable patient response and the clinical niches for which multiple are required; 6) the alternative formulations (vaginal ring, patch, IM and SQ injection) are required for adequate clinical coverage; and 7) none of the reviewed contraceptives are sufficiently less clinically effective than the others to be classified as non-formulary based on clinical issues alone.

COMMITTEE ACTION: The P&T Committee voted (15 for, 0 opposed, 0 abstained, 3 absent) to accept the clinical conclusion as stated above.

B. Contraceptive UF Relative Cost Effectiveness: The P&T Committee evaluated the relative cost-effectiveness of the contraceptive agents in relation to safety, tolerability, effectiveness, and clinical outcomes of the other agents in the class. Information considered by the P&T Committee included but was not limited to sources of information listed in 32 C.F.R. 199.21(e) (2).

The clinical review identified 35 unique contraceptive entities, the majority of which are available generically. For clinical comparison, these agents were classified into one of 11 categories based upon their estrogen content, phasic formulation, or route of administration. This classification system was also used in the economic review. However, for the initial cost assessment, the contraceptives were stratified into three broad groups: 1) OCs available only as brand-name products; 2) OCs available generically; and 3) non-oral contraceptives.

Respectively, these groups represented 20%, 53%, and 27% of the total annual contraceptive drug spend.

The initial cost assessment was based on average weighted cost per cycle across the MHS. This assessment found generically available oral contraceptives to be, in general, more cost-effective than brand name oral contraceptives and non-orally administered contraceptives. Additionally, it was determined that further opportunity exists to obtain lower prices for generic agents through national pharmaceutical contracts. For these reasons, the P&T Committee concluded that all generically available contraceptives should be maintained on the UF.

The P&T Committee also concluded that despite a somewhat higher average weighted cost per cycle for non-orally administered contraceptives (Nuvaring, Ortho Evra, Depo-Provera and equivalents, Depo-subq Provera 104) compared to generically available OCs, these agents should remain on the UF to ensure clinical coverage for patients who need these methods of administration. Likewise, the P&T Committee concluded that Plan B should remain on the UF, because of the clinical advantages of this progestogen-only product over other OCs for emergency contraception. The P&T Committee also discussed availability of Plan B from the TMOP, which currently does not fill prescriptions for Plan B. Although Plan B must be used within 72 hours of unprotected intercourse to be effective, which is not possible via mail order, the P&T Committee agreed that: (1) Under 32 CFR 199.21(h)(2)(i), formulary pharmaceutical agents are required to be available under the Pharmacy Benefits Program from all four points of service identified in paragraph 199.21(h)(1), except for military treatment facilities which are required only to have available BCF agents, with other formulary agents based upon their scope of practice; (2) consistent with this requirement, other medications which must be used acutely are available through mail order (e.g., antibiotics); and (3) this requirement of availability through mail order can ameliorate access problems.

A CMA and BIA were performed to determine the relative cost-effectiveness of the brand name oral contraceptives. The comparators for these analyses were the OCs within the same subgroup (as defined by the clinical review) as the brand name agent being analyzed. The brand name contraceptives considered in these analyses were: Estrostep Fe, Ovcon-35, Ovcon-50, Yasmin, Yaz, Ortho Tri-Cyclen Lo, and Seasonale.

The results of each category-specific CMA were incorporated into a BIA to account for other factors and costs associated with a potential decision to recommend non-formulary status for one or more brand-name contraceptive agents. The BIA accounted for market share migration, cost reductions associated with non-formulary cost shares, and medical necessity processing fee. Based on the CMA and BIA results of the combined category-specific analyses, the P&T Committee agreed that Yasmin, Yaz, and Ortho Tri-Cyclen Lo offered clinical and/or economic value for retention on the UF. The P&T Committee agreed that Seasonale, Ovcon-35, Ovcon-50, and Estrostep Fe should be non-formulary, because the category-specific cost-minimization analyses showed clinically similar alternatives were available at a significantly lower cost.

Conclusion: The P&T Committee, based upon its collective professional judgment, voted (15 for, 0 opposed, 0 abstained, 3 absent) to accept the UF cost analysis presented by the PEC. The P&T Committee concluded that Seasonale (EE 30 mcg; levonorgestrel 0.15 mg in special packaging for extended use); Ovcon 35 (EE 35 mcg; 0.4 mg norethindrone); Ovcon 50 (EE 50 mcg; norethindrone 1 mg), and Estrostep Fe (EE 20/30/35 mcg; norethindrone 1 mg) were not cost-effective relative to other contraceptive agents with similar clinical attributes. Taking into consideration the conclusions from the relative clinical effectiveness and relative

cost-effectiveness determinations of the contraceptive agents, and other relevant factors, the P&T Committee recommended that Seasonale, Ovcon-35, Ovcon-50 and Estrostep Fe be classified as non-formulary under the UF, and that Yasmin, Yaz, Ortho Tri-Cyclen Lo, Ortho Evra patches, Nuvaring, Depo-Provera, Depo-subq Provera 104, Plan B, and all generically available OCs be retained on the UF (See Table 1 on Pages 19-20 for a complete list of generically available OCs).

COMMITTEE ACTION: The P&T Committee, based upon its collective professional judgment, voted (14 for, 0 opposed, 1 abstained, 3 absent) to recommend Seasonale, Ovcon-35, Ovcon-50 and Estrostep Fe be classified non-formulary under the UF, with Yasmin, Yaz, Ortho Tri-Cyclen Lo, Ortho Evra patches, Nuvaring, Depo-Provera, Depo-subq Provera 104, and all generically available contraceptives (and equivalents) being added to the UF. In a separate vote, the P&T Committee recommended (12 for, 1 opposed, 3 abstained, 2 absent) that Plan B should continue to be classified as formulary on the UF.

The P&T Committee also voted (11 for, 2 opposed, 3 abstained, 2 absent) to recommend that Plan B be available from the TMOP; with a quantity limit of one Plan B package per copay applying to prescriptions filled by TMOP and retail network pharmacies.

C. Contraceptive Agents UF Medical Necessity Criteria: Based on the clinical evaluation of contraceptive agents, and the conditions for establishing medical necessity for a non-formulary medication provided for in the UF rule, the P&T Committee recommended the following medical necessity criteria for the combined OCs that were recommended for non-formulary status:

1) Use of formulary combined OCs is contraindicated.

2) The patient has experienced significant adverse effects from formulary combined OCs, or is likely to experience significant adverse effects from formulary combined OCs, and is expected to tolerate a non-formulary contraceptive agent.

3) Use of formulary combined OCs has resulted in therapeutic failure.

The P&T Committee agreed that it was extremely unlikely that a non-formulary contraceptive agent would truly be medically necessary, given the number and variety of contraceptive agents recommended for formulary status and the inclusion of contraceptives that are very similar to the recommended non-formulary agents.

COMMITTEE ACTION: The P&T Committee voted (14 for, 0 opposed, 1 abstained, 3 absent) to approve the medical necessity criteria.

D. Contraceptive Agents UF Implementation Plan: Because a high proportion of beneficiaries who would be affected by this formulary action are receiving Seasonale, which necessarily requires a 90-day prescription (about 11,000 DoD beneficiaries receive one or more prescriptions for Seasonale annually, out of about 23,000 patients with one or more prescriptions annually for Seasonale, Ovcon-35, Ovcon-50, or Estrostep Fe), the P&T Committee recommended an effective date no later than the first Wednesday following a 180-day implementation period. The implementation period will begin immediately following approval by the Director, TMA.

MTFs will not be allowed to have Seasonale, Ovcon-35, Ovcon-50, or Estrostep Fe on their local formularies. MTFs will be able to fill non-formulary requests for these agents only if both of the following conditions are met: 1) the prescription must be written by a MTF provider, and

2) medical necessity is established. MTFs may (but are not required to) fill a prescription for non-formulary contraceptives written by a non-MTF provider to whom the patient was referred, as long as medical necessity has been established.

COMMITTEE ACTION: The P&T Committee recommended (14 for, 0 opposed, 1 abstained, 3 absent) an effective date no later than the first Wednesday following a 180-day implementation period. The implementation period will begin immediately following the approval by the Director, TMA.

E. Contraceptive Agents BCF Review and Recommendations

The P&T Committee had previously determined that at least one but no more than two contraceptive products would be added to the BCF in each of the following subgroups. The P&T Committee could also consider addition of contraceptives in other subgroups, if needed. Based on the relative clinical effectiveness and cost effectiveness of the agents within each subgroup recommended for UF addition and taking into account the desire to maximize clinical coverage by providing a wide array of products within the most commonly used subgroups, the P&T Committee recommended the following OCs for BCF status.

- *Monophasic OCs with 20 mcg EE*
  - EE 20 mcg; 3 mg drospirenone (Yaz)
  - EE 20 mcg; 0.1 mg levonorgestrel (Alesse, Levlite, or equivalent)
- *Monophasic OCs with 30 mcg EE*
  - EE 30 mcg; 3 mg drospirenone (Yasmin)
  - EE 30 mcg; levonorgestrel 0.15 mg (Nordette or equivalent; excludes Seasonale)
- *Monophasic OCs with 35 mcg EE*
  - EE 35 mcg; 1 mg norethindrone (Ortho-Novum 1/35 or equivalent)
  - EE 35 mcg; 0.25 mg norgestimate (Ortho-Cyclen or equivalent)
- *Triphasic OCs*
  - 25 mcg EE; 0.18/0.215/0.25 mg norgestimate (Ortho Tri-Cyclen Lo)
  - 35 mcg EE; 0.18/0.215/0.25 mg norgestimate (Ortho Tri-Cyclen or equivalent)
- *Progestogen-only OCs*
  - 0.35 mg norethindrone (Nor-QD, Ortho Micronor, or equivalent)

The P&T Committee extensively discussed addition of the vaginal ring product (Nuvaring) to the BCF. Factors supporting addition included potential compliance advantages with once monthly dosing, a low adverse effect profile, and positive provider comments. The major factor opposing addition was the P&T Committee's uncertainty as to whether the clinical advantages outweighed the substantially higher cost per cycle compared to the OCs recommended for the BCF. The P&T Committee ultimately voted not to recommend Nuvaring for the BCF (6 for, 7 opposed, 2 abstained, 3 absent).

The P&T Committee noted that BPA prices submitted by manufacturers contingent upon UF and BCF status had a substantial impact on cost-effectiveness, particularly for some of the brand-name products (e.g., Yasmin, Yaz, and Ortho Tri-Cyclen Lo), which resulted in BCF recommendations that should broaden clinical coverage and reduce the unit cost of these widely used contraceptive products at MTFs. MTFs considering formulary status for products previously on the BCF should take into consideration local needs, as well as the potential that further cost reductions for generically available products may result from national contracting initiatives.

COMMITTEE ACTION: The P&T Committee voted (14 for, 0 opposed, 1 abstained, 3 absent) to recommend the following contraceptive agents for the BCF:

- EE 20 mcg; 3 mg drospirenone (Yaz)
- EE 20 mcg; 0.1 mg levonorgestrel (Alesse, Levlite, or equivalent)
- EE 30 mcg; 3 mg drospirenone (Yasmin)
- EE 30 mcg; levonorgestrel 0.15 mg (Nordette or equivalent; excludes Seasonale)
- EE 35 mcg; 1 mg norethindrone (Ortho-Novum 1/35 or equivalent)
- EE 35 mcg; 0.25 mg norgestimate (Ortho-Cyclen or equivalent)
- EE 25 mcg; 0.18/0.215/0.25 mg norgestimate (Ortho Tri-Cyclen Lo)
- EE 35 mcg; 0.18/0.215/0.25 mg norgestimate (Ortho Tri-Cyclen or equivalent)
- 0.35 mg norethindrone (Nor-QD, Ortho Micronor, or equivalent)

9. ABBREVIATED CLASS REVIEWS: HISTAMINE-2 (H2) BLOCKERS; HMG-Co A REDUCTASE INHIBITORS (STATINS), COMBINATION PRODUCTS, AND ADD-ON THERAPIES OF EZETIMIBE AND NIACIN; AND NEWER SEDATIVE HYPNOTIC AGENTS

Portions of the clinical reviews for each class were presented to the Committee. The Committee provided expert opinion regarding those clinical outcomes considered most important for the PEC to use in completing the clinical effectiveness review, and for developing the appropriate cost effectiveness models. Both the clinical and economic analyses of these three classes will be completed during the August 2006 meeting; no action necessary.

10. ADJOURNMENT

The second day of the meeting adjourned at 1600 hours on May 10, 2006. The dates of the next meeting are August 15-17, 2006.

*The topical antifungal drug class excludes vaginal products and products for onychomycosis (e.g., ciclopirox topical solution [Penlac])

Appendix B – Table 2. Newly Approved Drugs May 2006 DoD P&T Committee Meeting

Medication & Mechanism of Action	FDA approval date; FDA-approved indications	Committee Recommendation
Insulin detemir Injection (Levemir); Novo Nordisk**;** long-acting insulin	Jun 05: Treatment of insulin dependent diabetes mellitus in adults requiring long acting insulin for control of hyperglycemia. Oct 05: Treatment of pediatric Type I DM	No Uniform Formulary recommendation at this meeting. Consideration of Uniform Formulary status deferred until the injectable medications for diabetes drug class is reviewed.
Insulin glulisine injection (Apidra); Sanofi-Aventis; ultra short acting insulin analogue	Apr 04: Treatment of insulin dependent diabetes mellitus in adults requiring ultra short acting insulin for control of hyperglycemia	No Uniform Formulary recommendation at this meeting. Consideration of Uniform Formulary status deferred until the injectable medications for diabetes drug class is reviewed.
Ranolazine tablets (Ranexa); CV Therapeutics**;** partial fatty oxidase inhibitor	Jan 06: Treatment of chronic angina when used in combination with amlodipine, beta blockers or nitrates	No Uniform Formulary recommendation at this meeting. Consideration of Uniform Formulary status deferred until the miscellaneous cardiovascular drug class is reviewed.
Sunitinib capsules (Sutent); Pfizer**;** multi-kinase inhibitor	Dec 05 (priority review); Treatment of gastrointestinal stromal tumor after disease progression on, or intolerance to, imatinib (Gleevec). Treatment of advanced renal cell carcinoma	No Uniform Formulary recommendation at this meeting. Consideration of Uniform Formulary status deferred until oral cancer drug class is reviewed. Quantity limits recommended: TMOP: 50 mg: #60 caps/84 days, 25 mg: #120 caps/84 days, 12.5 mg: #180 caps/84 days. Retail Network: 50 mg: #30 caps/30 days, 25 mg:#60 caps/30 days, 12.5 mg: #120 caps/30 days
Lenalidomide capsules (Revlimid); Celgene**;** immunomodulatory drug (thalidomide analogue)	Dec 05: Treatment of myelodsyplastic syndromes in transfusion dependent patients with del 5q cytogenetic abnormality	No Uniform Formulary recommendation at this meeting. Consideration of Uniform Formulary status deferred until oral cancer drug class is reviewed.
Mecasermin rinfabate injection (Iplex); Insmed Pharmaceuticals; recombinant human insulin-I-like growth factor-1 (IGF-1)	Aug 05: Long-term treatment of growth failure in children with severe primary IGF-1 deficiency or with growth hormone gene deletion who have developed neutralizing antibodies to growth hormone	No Uniform Formulary recommendation at this meeting. Consideration of Uniform Formulary status deferred until growth hormone / IGF-1 drug class is reviewed. Added to existing PA criteria and forms for mecasermin (Increlex).

VTE	venous thromboembolism

DECISION PAPER:

FEBRUARY 2006
DEPARTMENT OF DEFENSE PHARMACY AND THERAPEUTICS COMMITTEE RECOMMENDATIONS

1. CONVENING

2. ATTENDANCE

3. REVIEW MINUTES OF LAST MEETING

4. ITEMS FOR INFORMATION

5. REVIEW OF RECENTLY APPROVED AGENTS

The P&T Committee was briefed on two new agents that had been approved by the Food and Drug Administration (FDA) (Appendix B – Table 2). Neither of the medications fall into drug classes already reviewed by the P&T Committee, therefore Uniform Formulary (UF) consideration was deferred until the corresponding drug class reviews are completed. The Committee reviewed one new drug for quantity limits. Sorafenib (Nexavar) is an oral multi-kinase inhibitor approved for treatment of patients with advanced renal cell carcinoma. It is available in 200 mg tablets and is administered in a dose of 2 tabs given twice daily. Quantity limits were recommended for sorafenib since there is a risk of discontinuation of therapy due to poor patient prognosis or drug-related adverse effects. Other oral chemotherapy drugs (imatinib, erlortinib) have quantity limits. The manufacturer of sorafenib has instituted a restricted distribution system which limits the quantity dispensed to a 30-day supply. Sorafenib is not currently available from the TMOP, due to the restricted distribution system.

COMMITTEE ACTION: The DoD P&T Committee voted (15 for, 0 opposed, 1 abstained, 2 absent) to recommend that sorafenib have quantity limits of 180 tablets per 45 days (TMOP), should the product become available from the TMOP, or 120 tablets per 30 days from the TRRx. (See paragraph 5 on pages 10-11 of P&T Committee minutes.)

*Director, TMA, Decision***:** ☑Approved ☐ Disapproved

Approved, but modified as follows:

6. OVERACTIVE BLADDER (OAB) DRUG CLASS REVIEW

The P&T Committee evaluated the relative clinical effectiveness and cost effectiveness of the antimuscarinic drugs used to treat over active bladder. The overactive bladder therapeutic class was defined as: oxybutynin immediate release (Ditropan tablets/solution or generic) oxybutynin sustained release (Detrol XL), oxybutynin transdermal (Oxytrol), tolterodine immediate release (Detrol), tolterodine sustained release (Detrol LA), trospium (Sanctura),

solifenacin (Vesicare), and darifenacin (Enablex). This class is now ranked 28th in Military Health System (MHS) drug class expenditures at a cost of $55 million annually.

The P&T Committee voted (16 for, 0 opposed, 1 abstained, 1 absent) that for the purposes of the UF clinical review none of the OABs have a significant clinically meaningful therapeutic advantage in terms of safety, effectiveness, or clinical outcome over the other OABs.

Based on the results of the cost-effectiveness analysis (CEA) and other clinical and cost considerations, the Committee agreed (15 for, 0 opposed, 0 abstention, 3 absent) that a group of OAB agents including tolterodine sustained release, oxybutynin sustained release, oxybutynin immediate release, solifenacin, and darifenacin represented the best overall value to the DoD for the treatment of OAB across all three points of service.

A. COMMITTEE ACTION: Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of the OAB agents, and other relevant factors, the P&T Committee voted (15 for, 0 opposed, 0 abstention, 3 absent) to recommend that tolterodine immediate release, oxybutynin patch, and trospium be classified as non-formulary under the UF and that tolterodine sustained release, oxybutynin sustained release, oxybutynin immediate release, solifenacin and darifenacin classified as formulary on the UF. (See paragraphs 6A and 6B on pages 11-16 of P&T Committee minutes for criteria.)

*Director, TMA, Decision***:** ☑Approved ☐ Disapproved

Approved, but modified as follows:

B. COMMITTEE ACTION: Based on the clinical evaluations of tolterodine immediate release, oxybutynin patch, trospium and the conditions for establishing medical necessity for a non-formulary medication provided for in the UF rule, the P&T Committee recommended (15 for, 0 opposed, 1 abstained, 2 absent) medical necessity criteria for the OAB agents. (See paragraph 6C on pages 16-17 of P&T Committee minutes for criteria.)

*Director, TMA, Decision***:** ☑Approved ☐ Disapproved

Approved, but modified as follows:

C. COMMITTEE ACTION: The P&T Committee recommended (13 for, 2 opposed, 1 abstained, 2 absent) an effective date no later than the first Wednesday following a 60-day implementation period. The implementation period will begin immediately following the approval by the Director, TMA. (See paragraph 6D on page 17 of P&T Committee minutes for rationale.)

*Director, TMA, Decision***:** ☐Approved ☑ Disapproved

~~Approved, but modified as follows~~: *"I note that the BAP recommended a 120 day implementation period. I have increased the implementation period to 90 days."*

D. COMMITTEE ACTION: Based on the relative clinical and cost effectiveness analyses, the P&T Committee voted (15 for, 0 opposed, 1 abstained, 2 absent) to recommend oxybutynin immediate release and tolterodine sustained release as the Basic Core Formulary (BCF) agents. (See paragraph 6E on page 17 of P&T Committee minutes for rationale.)

*Director, TMA, Decision***:** ☑Approved ☐ Disapproved

Approved, but modified as follows:

7. MISCELLANEOUS ANTIHYPERTENSIVE AGENTS DRUG CLASS REVIEW

The P&T Committee evaluated the relative clinical effectiveness and cost effectiveness of the miscellaneous antihypertensive agents marketed in the United States. The class was defined to include the angiotensin converting enzyme (ACE) inhibitor/calcium channel blocker (CCB) combinations amlodipine/benazepril (Lotrel), felodipine/enalapril (Lexxel), and verapamil sustained release/trandolapril (Tarka); the direct acting vasodilators (hydralazine, minoxidil); the centrally acting alpha-2 agonists (clonidine, methyldopa, guanabenz, guanfacine); the peripheral alpha-1 antagonists (prazosin); the adrenergic antagonists (reserpine, guanadrel, guanethidine); and the ganglionic blockers (mecamylamine). Together these drugs account for approximately $27M annually and are ranked 53rd in MHS drug class expenditures.

The P&T Committee voted (16 for, 0 opposed, 1 abstained, 1 absent) that for the purposes of the UF clinical review the following clinical conclusions applied: (1) there is no evidence that any one ACE/CCB combo is more effective relative to another for lowering blood pressure; (2) there is more evidence to support the use of amlodipine/benazepril and verapamil sustained release/trandolapril in sub-populations of patients with hypertension than felodipine/enalapril; (3) there is insufficient evidence to conclude that any one ACE/CCB combo is superior to another for reducing risk of cardiovascular outcomes in patients with hypertension; (4) safety/tolerability profiles of the ACE/CCB combos are primarily dictated by the CCB component; (5) there is no evidence to suggest that amlodipine/benazepril or felodipine/ enalapril would be superior to the other in terms of safety/tolerability. Verapamil sustained release/trandolapril has unique safety issues, due to the verapamil component; (6) persistence rates with amlodipine/benazepril may be improved by 7%-22% compared to the individual agents administered together; (7) transdermal clonidine is not a candidate for non-formulary designation on the UF due to its unique niche in several patient sub-groups and lower risk of rebound hypertension upon drug discontinuation; (8) Use of the remaining miscellaneous antihypertensive drugs is limited by bothersome tolerability profiles, however, several drugs maintain unique roles for treating hypertension and non-cardiovascular conditions.

Based on the results of the CEA and other clinical and cost considerations, the Committee agreed (16 for, 0 opposed, 1 abstention, 1 absent) that a group of miscellaneous antihypertensive agents including amlodipine/benazepril, the direct acting vasodilators (hydralazine, minoxidil); the centrally acting alpha-2 agonists [(clonidine tablets and patches), methyldopa, guanabenz, guanfacine]; the peripheral alpha-1 antagonists (prazosin); the adrenergic antagonists (reserpine, guanadrel, guanethidine); and the ganglionic blockers

(mecamylamine) represented the best overall value to the DoD in the class of miscellaneous antihypertensive agents.

A. COMMITTEE ACTION: The P&T Committee, based upon its collective professional judgment, voted (11 for, 4 opposed, 2 abstention, 1 absent) to recommend that felodipine/ enalapril (Lexxel) and verapamil/trandolapril (Tarka) be classified as non-formulary under the UF, with clonidine tablets, clonidine patches, amlodipine/benazepril (Lotrel), hydralazine, minoxidil, methyldopa, guanabenz, guanfacine, reserpine, guanadrel, guanethidine, and mecamylamine remaining on the UF. (See paragraphs 7A and 7B on pages 18-24 of P&T Committee minutes for criteria.)

*Director, TMA, Decision***:** ☑Approved ☐ Disapproved

Approved, but modified as follows: *"I note the BAP's concern about having Lotrel as UF agent when amlodipine is non-formulary. 50K beneficiaries use Lotrel. Keeping this drug on the UF maintains the option of an ACE/CCB combo for these and other beneficiaries."*

B. COMMITTEE ACTION: Based on the clinical evaluation of felodipine/enalapril (Lexxel) and verapamil/trandolapril (Tarka) and the conditions for establishing medical necessity for a non-formulary medication provided for in the UF rule, the P&T Committee recommended (15 for, 0 opposed, 1 abstained, 2 absent) medical necessity criteria for these agents. (See paragraph 7C on page 24 of P&T Committee minutes for criteria.)

*Director, TMA, Decision***:** ☑Approved ☐ Disapproved

Approved, but modified as follows:

C. COMMITTEE ACTION: The P&T Committee recommended (16 for, 0 opposed, 0 abstained, 2 absent) an effective date no later than the first Wednesday following a 60-day implementation period. The implementation period will begin immediately following approval by the Director, TMA. (See paragraph 7D on page 24 of P&T Committee minutes for rationale.)

*Director, TMA, Decision***:** ☐Approved ☑ Disapproved

~~Approved, but modified as follows~~: *"I note that the BAP recommended a 120 day implementation period. I have increased the implementation period to 90 days."*

D. COMMITTEE ACTION: Based on the relative clinical and cost effectiveness analyses, the P&T Committee voted (16 for, 0 opposed, 1 abstained, 1 absent) to recommend one combination agent [amlodipine/benazepril (Lotrel)] and two single agents (hydralazine and clonidine tablets) as the BCF agents. (See paragraph 7E on page 24 of P&T Committee minutes for rationale.)

*Director, TMA, Decision***:** ☑Approved ☐ Disapproved

Approved, but modified as follows:

8. GAMMA-AMINOBUTYRIC ACID (GABA)-ANALOG DRUG CLASS REVIEW

The DoD P&T Committee evaluated the relative clinical effectiveness of the GABA-analog agents marketed in the United States. The class was defined to include gabapentin (Neurontin and various generics), pregabalin (Lyrica) and tiagabine (Gabatril). Although gabapentin, pregabalin, and tiagabine all have FDA indicates as adjunctive therapy (added to other antiepileptic drugs) in the treatment of partial seizures, the Committee's review focused most heavily on the use of these agents for the treatment of various types of neuropathic pain. Together these drugs account for approximately $148M annually and are ranked 6th in MHS drug class expenditures.

The P&T Committee voted (16 for, 0 opposed, 1 abstained, 1 absent) that for the purposes of the UF clinical review the following clinical conclusions applied: (1) the efficacy of gabapentin and pregabalin for treating pain associated with either diabetic peripheral neuropathy (DPN) or post-herpetic neuropathy (PHN) appears similar; (2) gabapentin is the only GABA-analog that has shown modest efficacy in treating other types of neuropathic pain based on published clinical trials; (3) there is insufficient data regarding the efficacy of tiagabine in patients with neuropathic pain syndromes to make definitive conclusions; (4) there appear to be no major differences in the efficacy of gabapentin, pregabalin, or tiagabine for use as adjunctive treatment of partial seizures; (5) the safety and tolerability profiles of gabapentin and pregabalin are more favorable compared to tiagabine; (6) there appear to be only minor differences in the tolerability profiles of gabapentin and pregabalin, when evaluating the incidence of somnolence, dizziness, and peripheral edema; (7) there are minor differences in other factors between the drugs, including use in pediatrics, pharmacokinetic profiles, titration schedules, onset of effect, and controlled substance status. Overall the Committee agreed based on clinical usefulness alone, there was no basis for classifying any of the GABA analogs as non-formulary.

Based on the results of the clinical and cost-effectiveness analyses, the Committee agreed (16 for, 0 opposed, 0 abstained, 2 absent) that gabapentin was the more cost effective GABA-analog drug for the treatment of neuropathic pain.

A. COMMITTEE ACTION: Taking into consideration the conclusions from the relative clinical effectiveness and the relative cost effectiveness determinations for the GABA-analog drugs, and other relevant factors, the P&T Committee recommended (14 for, 2 opposed, 0 abstained, 2 absent) that pregabalin be classified as non-formulary under the UF, with gabapentin and tiagabine remaining on the UF. (See paragraphs 8A and 8B on pages 24-31 of P&T Committee minutes for criteria.)

*Director, TMA, Decision***:** ☑Approved ☐ Disapproved

Approved, but modified as follows: *"I agree with the concerns noted by some BAP members re off-label use of new drugs as first-line therapy when there are "tried and true" alternatives with known safety profiles. Lyrica remains available to those who need it under medical necessity criteria."*

B. COMMITTEE ACTION: Based on the clinical evaluations of pregabalin and the conditions for establishing medical necessity for a non-formulary medication provided for in the UF rule, the P&T Committee recommended (15 for, 1 opposed, 0 abstained, 2 absent) medical necessity criteria for the GABA-analog agents. (See paragraph 8C on pages 31-32 of P&T Committee minutes for criteria.)

*Director, TMA, Decision***:** ☑Approved ☐ Disapproved

Approved, but modified as follows:

C. COMMITTEE ACTION: Due to the relatively low number of patients that will be affected by this formulary action, the P&T Committee recommended (15 for, 0 opposed, 0 abstained, 3 absent) an effective date no later than the first Wednesday following a 60-day implementation period. The implementation period will begin immediately following the approval by the Director, TMA. (See paragraph 8D on page 32 of P&T Committee minutes for rationale.).

*Director, TMA, Decision***:** ☑Approved ☐ Disapproved

Approved, but modified as follows:

D. COMMITTEE ACTION: Based on the relative clinical and cost effectiveness analyses, the P&T Committee voted (16 for, 0 opposed, 0 abstained, 2 absent) to recommend gabapentin as the BCF agent. (See paragraph 8E on page 32 of P&T Committee minutes for rationale.)

*Director, TMA, Decision***:** ☑Approved ☐ Disapproved

Approved, but modified as follows:

9. ABBREVIATED CLASS REVIEWS: THIAZOLIDINEDIONES (TZDS), ORAL ANTIEMETIC AGENTS; CONTRACEPTIVE AGENTS

Portions of the clinical reviews of each class were presented to the Committee. The Committee provided expert opinion regarding clinical outcomes of importance for the purpose of developing appropriate cost effectiveness models. Both the clinical and economic analyses of each class will be completed during the May 2006 meeting; no action necessary.

APPENDIX A – TABLE 1. Implementation Status of UF Decisions

APPENDIX B – TABLE 2. Newly Approved Drugs

APPENDIX C – TABLE 3. Abbreviations

DECISION ON RECOMMENDATIONS

Director, TMA, decisions are as annotated above.

_____//signed//_____
William Winkenwerder, Jr., M.D.
Date: 26 April 2006

Department of Defense
Pharmacy and Therapeutics Committee Minutes

17 February 2006

1. CONVENING

The Department of Defense (DoD) Pharmacy and Therapeutics (P&T) Committee convened at 0800 hours on 14 February 2006 at the DoD Pharmacoeconomic Center (PEC), Fort Sam Houston, Texas.

2. ATTENDANCE

A. Voting Members Present

CAPT Patricia Buss, MC, USN	DoD P& T Committee Chair
CDR Mark Richerson, MSC, USN	DoD P& T Committee Recorder
CDR Bill Blanche, MSC, USN	DoD Pharmacy Programs, TMA
Maj David Carnahan, MC	Air Force, Internal Medicine Physician
Maj Michael Proffitt, MC	Air Force, OB/GYN Physician
LtCol Brian Crownover, MC	Air Force, Physician at Large
LtCol Everett McAllister, BSC	Air Force, Pharmacy Officer
LCDR Scott Akins, MC	Navy, Pediatrics Physician
CDR Brian Alexander, MC	Navy, Physician at Large
LCDR Joe Lawrence MSC *for* CAPT David Price, MSC	Navy, Pharmacy Officer
COL Doreen Lounsbery, MC	Army, Internal Medicine Physician
MAJ Roger Brockbank, MC	Army, Family Practice Physician
MAJ Paul Garrett MC *for* COL Joel Schmidt, MC	Army, Physician at Large
LTC Peter Bulatao, MS *for* COL Isiah Harper, MS	Army, Pharmacy Officer
CDR Vernon Lew, USPHS	Coast Guard, Pharmacy Officer

3. REVIEW MINUTES OF LAST MEETING

A. Corrections to the minutes – November 2005 DoD P&T meeting minutes were approved as written, with no corrections noted.

B. November minutes approval – Dr. William Winkenwerder, Jr., M.D. approved the minutes of the November 2005 DoD P&T Committee on 19 January 2006.

4. ITEMS FOR INFORMATION

TMA and DoD PEC staff members briefed the P&T Committee on the following:

A. Beneficiary Advisory Panel (BAP) Briefing: CAPT Buss, LtCol Bennett and LtCol Crownover briefed the members of the DoD P&T committee regarding the 15 December 2005 BAP meeting. The Committee was briefed on BAP comments regarding DoD P&T Committee's Uniform Formulary (UF) and implementation recommendations.

B. Implementation Status of UF Decisions: Mr. Dave Bretzke briefed the members of the Committee on the progress of implementation for drug classes reviewed for UF status since

February of 2005 (see Appendix A – Table 1). The Committee made the following observations:

- Utilization in all UF classes remains stable suggesting continued access to drugs within the reviewed classes.
- Collectively, as a percent of prescriptions dispensed, utilization of UF agents across all reviewed drug classes and points of service (MTF, mail, retail) have increased, while utilization of non-formulary agents has decreased. Among the UF decisions that have been implemented since the first UF DoD P&T meeting in February 2005 DoD there has been a 34% reduction in the use of non-formulary agents. Among all drug classes reviewed by the Committee to date, including those classes where implementation has only just begun, there has been a 17% reduction in the use of agents designated as non-formulary.
- Success in terms of generating increased market share for UF agents (while decreasing market share for non-formulary agents) varies by class and by point of service.
    - Formulary decisions resulting in a higher degree of drug class restrictiveness (i.e., phosphodiesterase-5 inhibitors) are generating better market share results than formulary decisions allowing multiple UF options within a drug class (i.e., angiotensin receptor blockers).
    - Market shares by point of service reflect the degree of utilization management applied to each point of service. The more highly managed points of service (ie., MTF, mail) are generating higher market shares of UF agents than the unmanaged point of service (i.e., retail).
- Overall market share projections for UF agents of 80% have not yet been realized. Although these projections were based on an implementation plan utilizing a one year time horizon, it is unlikely this degree of conversion will be achieved across all three points of service.
    - Models used to describe the relative economic comparison of agents within a drug class have been adjusted to reflect this information.
    - For the February 2006 drug classes evaluated for UF status, switch rates were reduced from 80% at all three points of service to approximately 70% at the MTF point of service and 30% in the retail and mail order sectors.

5. REVIEW OF RECENTLY-APPROVED AGENTS

The P&T Committee was briefed on two new agents recently approved by the Food and Drug Administration (FDA) (Appendix B – Table 2). Neither of the medications fall into drug classes already reviewed by the P&T Committee, therefore UF consideration was deferred until the corresponding drug class reviews are completed. The Committee reviewed one new drug for quantity limits. Sorafenib (Nexavar) is an oral multi-kinase inhibitor approved for treatment of patients with advanced renal cell carcinoma. Sorafenib is available in 200 mg tablets and is administered in a dose of 2 tabs given twice daily. Quantity limits were recommended for sorafenib since there is a risk of discontinuation of therapy due to poor patient prognosis or drug-related adverse effects. Other oral chemotherapy drugs (imatinib, erlortinib) do have quantity limits. The manufacturer of sorafenib has instituted a restricted distribution system

which limits the quantity dispensed to a 30-day supply. Sorafenib is not currently available from the TMOP, due to the restricted distribution system.

COMMITTEE ACTION: The DoD Pharmacy and Therapeutics (P&T) Committee voted (15 for, 0 opposed, 1 abstained, 2 absent) to recommend that sorafenib have quantity limits of 180 tablets per 45 days (TMOP), should the product become available from the TMOP, or 120 tablets per 30 days (TRRx).

6. OVERACTIVE BLADDER (OAB) DRUG CLASS REVIEW.

A. OAB Medications Relative Clinical Effectiveness Review: The P&T Committee evaluated the relative clinical effectiveness of all the FDA-approved antimuscarinic drugs available in the U.S. for the treatment of overactive bladder. The OAB therapeutic class was defined as the antimuscarinics: oxybutynin immediate release (Ditropan tablets/solution or generic), oxybutynin sustained release (Detrol XL), oxybutynin transdermal (Oxytrol), tolterodine immediate release (Detrol), tolterodine sustained release (Detrol LA), trospium (Sanctura), solifenacin (Vesicare), and darifenacin (Enablex). The clinical review included consideration of pertinent information from a variety of sources determined by the P&T Committee to be relevant and reliable, including but not limited to sources of information listed in 32 CFR 199.21(e)(1). The P&T Committee was advised that there is a statutory presumption that pharmaceutical agents in a therapeutic class are clinically effective and should be included on the UF, unless the P&T Committee finds by a majority vote that a pharmaceutical agent does not have a significant, clinically meaningful therapeutic advantage in terms of safety, effectiveness, or clinical outcome over the other pharmaceutical agents included on the UF in that therapeutic class.

During a twelve month period ending 30 Sept 2005, 147,508 Military Health System (MHS) patients were prescribed an antimuscarinic drug for overactive bladder. This class is now ranked 28th in MHS drug class expenditures at a cost of $55 million annually.

1) Efficacy

Efficacy measures. The antimuscarinic drugs reviewed are FDA-approved for the treatment of OAB. Efficacy measures used in clinical trials include the following:

a. Weekly number of urge incontinence episodes and total (urge plus non-urge) urinary incontinence episodes
b. Daily micturition frequency for up to 7 consecutive days during the baseline period and for one or more periods prior to clinic visits
c. Daily frequency of urgency episodes
d. Daily severity of urgency episodes
e. Volume voided per micturition
f. Number of incontinence episodes resulting in a change of pad or clothing per week
g. Nocturnal awakenings per week due to OAB symptoms
h. Volume to first urge sensation
i. Volume to first detrusor contraction
j. Bladder capacity (volume)
k. Post-void residual volume

Efficacy results: No differences in efficacy were reported when the following trials were assessed: four studies comparing oxybutynin immediate release and tolterodine immediate

release; one study of trospium versus oxybutynin immediate release; four studies of oxybutynin sustained release versus oxybutynin immediate release; and one study comparing of tolterodine sustained release versus tolterodine immediate release.

Oxybutynin sustained release was found to be superior to tolterodine immediate release in one trial; conversely tolterodine sustained release was reported as superior in one comparative trial against oxybutynin immediate release. Conflicting results were reported in the trials comparing oxybutynin sustained release and tolterodine sustained release, however, the two products showed similar efficacy in the comparative clinical trial that had the most rigorous study design. Solifenacin (flexible dose) showed greater efficacy over tolterodine sustained release (fixed dose) in one trial, however the results may be explained by lack of dosage titration allowed in the tolterodine sustained release group. Another short term trial showed greater efficacy with solifenacin vs tolterodine immediate release in some, but not all, efficacy measures. There were no trials comparing darifenacin vs. other OAB drugs.

A comparison of the OAB drugs' effects on the primary efficacy was made by adjusting for placebo effect and standardizing for 24 hour results. This comparison was not designed to demonstrate superiority, but designed to provide a range of improvement. All of the OAB agents decreased incontinence episodes by 0.32 - 1.04 events per 24 hours and urinary frequency by 0.6 - 1.3 voids per 24 hours.

Efficacy conclusion: In controlled clinical trials in overactive bladder, there was a high placebo efficacy rate. All of the OAB drugs have shown statistical superiority over placebo in controlled trials, however the results are of questionable clinical significance. Despite the availability of several head-to-head comparative trials for the OAB drugs, it is difficult to determine superiority of one product over another, due to differences in study design. When the results of the comparative clinical trials are compared in terms of incontinent episodes, urinary frequency and volume/void, there is insufficient evidence to conclude that any one OAB drug is more efficacious than another.

2) Safety and Tolerability

Contraindications: All the OAB drugs carry a similar contraindication of use in patients with gastric retention, urinary retention and uncontrolled narrow angle glaucoma.

Serious side effects: Irreversible urinary retention is a possible serious side effect with all the drugs in the OAB class. Cases are rare especially with the use of long acting agents.

Common Side effects: The majority of the side effects are due to the anti-cholinergic properties inherent to the class. The most prevalent side effects are dry mouth, constipation, dry eyes, somnolence and nausea. The newer agents (solifenacin, darifenacin and trospium) cause similar rates of dry mouth as the older agents (tolterodine and oxybutynin). These newer OAB drugs cause more constipation than tolterodine and oxybutynin. In the clinical trials with the oxybutynin patch, patients treated with the patch had a lower anti-cholinergic side effect profile verses patients receiving tolterodine and oxybutynin oral formulations. However, the patch was associated with significant dermatological side effects resulting in patient withdrawal. Oxybutynin immediate release is listed on the Beer's Criteria indicating the drug's use should be limited in the elderly.

Evidence from short-term head-to-head comparison trials indicate a higher incidence of adverse events overall, and dry mouth specifically, with oxybutynin. The sustained release forms of each drug resulted in fewer adverse events and dry mouth when compared to formulations. Trospium causes less severe dry mouth although the overall incidence of dry mouth and short

term adverse events are similar to oxybutynin immediate release. The difference between drugs based on withdrawals is less clear. Two trials of solifenacin versus tolterodine showed similar rates of adverse events overall; one trial showed lower rates of dry mouth for tolterodine sustained release versus solifenacin.

Discontinuation Rates: One comparative long-term study assessed the discontinuation rate of tolterodine and oxybutynin immediate release over a 6-month period. Oxybutynin immediate release treatment resulted in a higher discontinuation rate and earlier withdrawal from therapy than patients receiving tolterodine. The discontinuation rates and withdrawal rates were high for both drugs. Uncontrolled studies reported that dry mouth is the most common adverse event, and found similar rates of adverse events and withdrawals between oxybutynin and tolterodine. One head-to-head trial of trospium versus oxybutynin reported more adverse effects attributed with oxybutynin, especially dry mouth.

Drug interactions: There is the potential for induction or inhibition of hepatic cytochrome P450 isoenzymes with all the OAB drugs except trospium. There are few studies evaluating the clinical effects of these drug interactions. All the OAB drugs have the potential to increase the anti-cholinergic effects when used concomitantly with other anti-cholinergic drugs, which increases the risk for adverse effects and toxicity. All the OAB drugs can potentially increase the risk for sedation when taken with other drugs with sedating effects.

Persistence: Persistence rates of less than 10% with the OAB drugs have been reported in the literature. In the MHS, after a 12 month evaluation period, the persistence rates for tolterodine sustained release, oxybutynin sustained release, and oxybutynin immediate release were 5% to 16%. There were insufficient numbers of prescriptions refilled for the three newest OAB drugs to determine persistent rates. MHS beneficiaries using TMOP were more persistent with OAB therapy than those beneficiaries using other points of service. Noted in the study were a number of patients refilling OAB drug prescriptions well after the due date. It is possible that patients are using the OAB drugs on an as needed basis as dictated by social situations

Safety/tolerability conclusion: Anti-cholinergic effects are the most bothersome adverse events with all the OAB drugs. The most frequently encountered adverse event is dry mouth, which occurs with a higher rate for immediate release formulations than with SR formulations. The highest frequency of dry mouth occurs with oxybutynin immediate release. The three newest OAB drugs (trospium, solifenacin, and darifenacin) do not substantially lower the rate of dry mouth compared with tolterodine or oxybutynin sustained release, but do cause a higher rate of constipation. An evaluation of prescription refill patterns in DoD shows low persistence rates with tolterodine and oxybutynin. There was not enough data available to adequately evaluate MHS persistence rates for trospium, solifenacin, and darifenacin.

3) Other Factors

Dosing: All of the agents in the class are dosed once daily except for trospium, oxybutynin immediate release, and tolterodine immediate release. Once daily dosing theoretically increases compliance. Oxybutynin sustained release is frequently dosed in a range of 5 mg to 15 mg daily in clinical trials. In contrast, DoD usage shows 20 mg to 30 mg daily more commonly used, which can potentially increase the risk of adverse events.

Special populations: Pediatrics: Oxybutynin immediate release and sustained release are FDA-approved for use in children 6 years and older. The manufactures of tolterodine are pursuing an indication for use in pediatric patients.

Pregnancy: All the OAB drugs are rated as pregnancy category C with the exception of oxybutynin which is rated category B.

DoD Provider Comments: DoD providers were most comfortable prescribing oxybutynin immediate release and tolterodine sustained release; these two drugs have been included on the BCF since 2002. Most providers favored tolterodine sustained release. A majority of respondents had heard of the newer agents, trospium, solifenacin and darifenacin, but over 80% had not yet prescribed the agents. Most providers reported that the side effect profiles seen with clinical usage were similar to what is reported in the literature. DoD providers overestimated MHS persistence rates at 43% compared to the actual rates of between 5% and 16%.

Other Factors Conclusion: There is no evidence to suggest clinical superiority of any one OAB drug over another based on differences in dosing and titration schedules or DoD provider opinion. For pediatric patients, oxybutynin is preferred at this time.

Overall Clinical Effectiveness Conclusion: The DoD P&T Committee concluded that: 1) when the results of the comparative clinical trials are compared in terms of incontinent episodes, urinary frequency and volume/void, there is insufficient evidence to conclude that any one OAB drug is more efficacious than another; 2) When similar dosage forms are compared (immediate release to immediate release; sustained release to sustained release) the side effect profiles are similar; 3) immediate release forms of the overactive bladder drugs induce more anti-cholinergic side effects than the sustained release forms; 4) the new agents, solifenacin and darifenacin, and trospium have an increased rate of constipation compared to oxybutynin sustained release and tolterodine sustained release; 5) oxybutynin is the only product which is approved for use in children at this time; 6) MHS persistence rates with all drugs in this class are very low, ranging between 16% and 55% at the end of a one year evaluation period; 7) DoD providers were most comfortable prescribing oxybutynin and tolterodine and had little experience with the newer agents.

COMMITTEE ACTION: The P&T Committee voted (16 for, 0 opposed, 1 abstained, 1 absent) that for the purposes of the UF clinical review, all the drugs reviewed for OAB were similar in terms of effectiveness and clinical outcome.

B. OAB UF Relative Cost Effectiveness:

The P&T Committee evaluated the relative cost-effectiveness of the OAB agents in relation to safety, tolerability, effectiveness, and clinical outcomes of the other agents in the class. Information considered by the P&T Committee included but was not limited to sources of information listed in 32 CFR 199.21(e) (2).

To determine the relative cost effectiveness of the OAB agents, two separate economic analyses were performed, a pharmacoeconomic analysis and budget impact analysis (BIA). From the preceding evidence-based relative clinical effectiveness evaluation, the P&T Committee concluded that, when comparing immediate release agents to immediate release agents and sustained release agents to sustained release agents, there was insufficient evidence to suggest that the OAB agents differed in regards to efficacy, safety, and tolerability in the treatment of OAB. Normally, such a conclusion would suggest cost-minimization to be the appropriate pharmacoeconomic analysis, however, in this case, to account for the differences in relative clinical effectiveness between the immediate release and sustained release agents in this therapeutic class, a cost-effectiveness analyses (CEA) was used. This was done based on the results of a sample based retrospective cohort database analysis. In a CEA, the agents within a therapeutic class are competed on two dimensions, cost and effect (outcomes).

A one-year sample-based retrospective cohort database analysis was performed on DoD MHS prescription data. The study population was comprised of DoD patients filling prescriptions for oxybutynin immediate release, oxybutynin sustained release, oxybutynin patch, tolterodine immediate release, tolterodine sustained release, and trospium between 01 July 2004 and 30 September 2005. Patients taking any OAB agent, in the 6 month period prior of their observed period of enrollment, were excluded to capture new users only. Note, darifenacin and solifenacin were not included in the study since these agents are new and lacked a year's worth of utilization data. The drug cost used in the analysis was the point of service adjusted total weighted average cost per day of treatment (for all three points of service) and the outcome of interest was adherence to treatment, where adherence to treatment was measured by total days of treatment. Theoretically, adherence to treatment is a surrogate indicator of efficacy, safety, and tolerability. In other words, a patient is more inclined to adhere to treatment if the agent works (efficacy) and is tolerated to the extent that the benefits of treatment outweighs the risk of side effects (tolerability and/or safety).

The results from the sample-based retrospective cohort database analysis were incorporated into a CEA. The cost used in the analysis for each agent was the mean cost of treatment for one year and the effect/outcome was the mean days of treatment for one year. Overall, the results of the CEA were as follows:

- Overall, oxybutynin immediate release was determined to be the most cost-effective agent and tolterodine sustained release was determined to be significantly more costly and effective along the efficiency frontier.
- Among the multi-dosed immediate release agents, oxybutynin immediate release was determined to be the most cost-effective agent; tolterodine immediate release was determined to be slightly more effective but significantly more costly (> 15-fold) compared to oxybutynin immediate release; and trospium immediate release was determined to be slightly less effective and significantly more costly (> 15-fold) compared to oxybutynin immediate release
- Among the once daily extended release agents, tolterodine sustained release was determined to be the most cost-effective agent; oxybutynin patch and sustained release tablet were dominated (more costly and less effective) compared to tolterodine sustained release.

Although the evidence-based relative clinical effectiveness evaluation determined that there was insufficient evidence to suggest that the OAB agents differed in regards to efficacy, safety, and tolerability in the treatment of OAB, this CEA based on a sample-based retrospective cohort database analysis suggests that differences do exist among the agents in regards to adherence to treatment.

Since darifenacin and solifenacin lacked sufficient utilization data to be included in the CEA analysis, the agents were evaluated on their point of service adjusted total weighted average cost per day of treatment only. The manufacturers of darifenacin and solifenacin submitted highly competitive prices for their respective agents, which made them significantly less costly compared to the most cost-effective single-dosed extended release agent, tolterodine sustained release. For purposes of this evaluation, the DoD P&T Committee assumed that darifenacin and solifenacin would have similar relative clinical effectiveness compared to tolterodine sustained release, based upon the conclusion of the overall relative clinical effectiveness presentation.

The results of the CEAs were subsequently incorporated into a BIA. A BIA accounts for other factors and costs associated with a potential decision to recommend that one or more agents be classified as non-formulary, such as: market share migration, cost reduction associated with non-formulary cost shares, and medical necessity processing fees. The goal of the BIA was to assist the Committee in determining which group of OAB agent's best met the majority of the clinical needs of the DoD population at the lowest cost to the MHS. Based on the BIA results and other clinical and cost considerations (oxybutynin sustained release is projected to go generic in 2006), the Committee agreed that a group of OAB agents that included: darifenacin, oxybutynin immediate release, oxybutynin sustained release, solifenacin, and tolterodine sustained release best achieved this goal when compared to other combination groups of OAB agents, and thus were determined to be more cost-effective relative to other combination groups.

*Conclusion**:*** The P&T Committee, based upon its collective professional judgment, voted (15 for, 0 opposed, 2 abstention, 1 absent) to accept the OAB pharmacoeconomic analyses presented by the PEC. The P&T Committee concluded that: tolterodine immediate release, oxybutynin patch, and trospium were not cost-effective relative to the other OAB agents. Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of the OAB agents, and other relevant factors, the P&T Committee recommended that tolterodine immediate release, oxybutynin patch, and trospium be classified as non-formulary under the UF and that darifenacin, oxybutynin immediate release, oxybutynin sustained release, solifenacin, and tolterodine sustained release be classified as formulary on the UF.

COMMITTEE ACTION: The P&T Committee, based upon its collective professional judgment, voted (15 for, 0 opposed, 0 abstention, 3 absent) to recommend that tolterodine immediate release, oxybutynin patch, and trospium be classified as non-formulary under the UF, with darifenacin, oxybutynin immediate release, oxybutynin sustained release, solifenacin, and tolterodine sustained release remaining on the UF. In considering the relative cost effectiveness of pharmaceutical agents in this class, the P&T Committee evaluated the costs of the agents in relation to the safety, effectiveness, and clinical outcomes of the other agents in the class. Information considered by the P&T Committee included but was not limited to sources of information listed in 32 CFR 199.21(e)(2).

C. OAB Drug UF Medical Necessity Criteria: Based on the clinical evaluation of overactive bladder drugs, and the conditions for establishing medical necessity for a non-formulary medication provided for in the UF rule, the P&T Committee recommended the following medical necessity criteria for these agents.

1) Use of the formulary overactive bladder drugs (oxybutynin immediate release, oxybutynin sustained release, tolterodine sustained release, solifenacin and darifenacin) are contraindicated, and the use of tolterodine immediate release, trospium, or oxybutynin patch is not contraindicated.

2) The patient has experienced or is likely to experience significant adverse effects from the formulary overactive bladder drugs (oxybutynin immediate release, oxybutynin sustained release, tolterodine sustained release, solifenacin and darifenacin) and the patient is expected to tolerate tolterodine immediate release, trospium, or oxybutynin patch.

3) Use of the formulary overactive bladder drugs (oxybutynin immediate release, oxybutynin sustained release, tolterodine sustained release, solifenacin and darifenacin) resulted in

therapeutic failure, and the patient is expected to respond to tolterodine immediate release, trospium, or oxybutynin patch (therapeutic failure as outlined on medical necessity form).

4) The patient has previously responded to the oxybutynin patch, and changing to the formulary overactive bladder drugs (oxybutynin immediate release, oxybutynin sustained release, tolterodine sustained release, solifenacin and darifenacin) would incur unacceptable risk. The Committee agreed that this criterion could apply because of the potentially lower risk of CNS effects with the oxybutynin patch.

5) There is no alternative formulary agent: The Committee agreed that this criterion could apply to the oxybutynin patch if the patient could not take oral medications.

COMMITTEE ACTION: The P&T Committee voted (15 for, 0 opposed, 1 abstained, 2 absent) to approve the medical necessity criteria.

D. OAB Drug UF Implementation Plan: Because of the low number of beneficiaries who would be affected by this formulary action (19,118 patients known to be taking tolterodine immediate release, trospium, or oxybutynin patch across the MHS), the P&T Committee recommended an effective date no later than the first Wednesday following a 60-day implementation period. The implementation period will begin immediately following approval by the Director, TMA.

MTFs will not be allowed to have tolterodine immediate release, trospium, or oxybutynin patch on their local formularies. MTFs will be able to fill non-formulary requests for these agents only if both of the following conditions are met: 1) the prescription must be written by a MTF provider, and 2) medical necessity is established. MTFs may (but are not required to) fill a prescription for tolterodine immediate release, trospium, or oxybutynin patch written by a non-MTF provider to whom the patient was referred, as long as medical necessity has been established.

COMMITTEE ACTION: The P&T Committee recommended (13 for, 2 opposed, 1 abstained, 2 absent) an effective date no later than the first Wednesday following a 60 day implementation period. The implementation period will begin immediately following the approval by the Director, TMA.

E. OAB Drug Basic Core Formulary (BCF) Review and Recommendations. The P&T Committee had previously determined that at least one but no more that two overactive bladder drugs would be added to the BCF based on the clinical and cost effectiveness reviews. As a result of the clinical and economic evaluations presented, the P&T Committee recommended that oxybutynin immediate release and tolterodine sustained release be added to the BCF.

COMMITTEE ACTION: The P&T Committee voted (15 for, 0 opposed, 1 abstained, 2 absent) to include oxybutynin immediate release and tolterodine sustained release on the BCF.

7. MISCELLANEOUS ANTIHYPERTENSIVE AGENTS DRUG CLASS REVIEW

A. Miscellaneous Antihypertensive Agents UF Relative Clinical Effectiveness: The P&T Committee evaluated the relative clinical effectiveness of the miscellaneous antihypertensive agents marketed in the United States. The drugs in the class included the angiotensin converting enzyme (ACE) inhibitor/calcium channel blocker (CCB) combinations amlodipine/ benazepril (Lotrel), felodipine/enalapril (Lexxel), and verapamil sustained release/trandolapril (Tarka); the direct acting vasodilators (hydralazine, minoxidil); the centrally acting alpha-2 agonists (clonidine, methyldopa, guanabenz, guanfacine); the peripheral alpha-1 antagonists

(prazosin); the adrenergic antagonists (reserpine, guanadrel, guanethidine); and the ganglionic blockers (mecamylamine). Information regarding the safety, effectiveness, clinical outcomes, and patient persistence rates of the ACE inhibitor/CCB combinations (ACE/CCB combos) was considered in depth. For the other miscellaneous antihypertensive agents, the Committee considered the place in therapy of the drugs in national hypertension guidelines, significant usage for conditions other than hypertension, existing MHS utilization, and adverse effect profiles. The clinical review included, but was not limited to, the requirements stated in the UF Rule.

1) *ACE inhibitor/CCB combinations:* The relative clinical effectiveness of the individual ACE inhibitors and calcium channel blockers was reviewed previously by the Committee. Refer to the minutes from the August 2005 P&T Committee meeting for the relative clinical effectiveness conclusion for these two drug classes.

   a) Pharmacology: Both amlodipine/benazepril and felodipine/enalapril contain a dihydropyridine (DHP) CCB. The verapamil component of verapamil sustained release /trandolapril is a non-dihyropyridine CCB. Verapamil reduces myocardial contractility and slows conduction through the atrioventricular node. The physiologic effect of slowed heart rate with the non-DHP CCBs is frequently used as a beneficial effect in patients with increased heart rate (e.g. atrial fibrillation). The DHPs do not slow cardiac conduction, but have peripheral vasodilatory effects. The individual ACE inhibitor components of the combo products (benazepril, enalapril, trandolapril) exhibit similar pharmacologic properties.

   The benefits of combining an ACE inhibitor with a CCB include additive blood pressure (BP) lowering effect due to differing mechanisms of action, attenuation of CCB-induced edema through addition of the ACE inhibitor, patient convenience due to simplified drug regimens, decreased pill burden, and potentially improved adherence with antihypertensive therapy.

   b) Efficacy for Hypertension:

   Place in Therapy: The three ACE/CCB combinations are all approved for the treatment of mild to moderate hypertension. The Joint National Commission VII (JNC VII) guidelines acknowledge that combination antihypertensive therapy may be necessary, and is likely to be used as first-line treatment of hypertension. The guidelines recommend use of a combination regimen, which should usually include a diuretic, as first-line therapy for stage 2 hypertension (BP $\geq$160/100 mm Hg), or for patients with compelling indications. Compelling indications for use of an ACE inhibitor include heart failure, post-myocardial infarction, high risk of coronary artery disease, diabetes, chronic kidney disease, or previous stroke; compelling indications for use of a CCB include diabetes and patients with high risk of coronary artery disease.

   Efficacy for lowering BP: All three products have clinical trial data showing enhanced efficacy when the combination product is compared to the single components administered individually. Data from the individual package inserts was used to compare BP lowering effects. Amlodipine/benazepril reduces systolic blood pressure (SBP) by 10-25 mmHg and diastolic blood pressure (DBP) by 6-13 mmHg, felodipine/enalapril reduces SBP by 14.2 mmHg and DBP by 12.6 mmHg, and verapamil/trandolapril reduces SBP by 13-22 mmHg, and DBP by 8-17 mmHg.

Effects in sub- populations of patients with hypertension: There are no published trials of felodipine/enalapril (Lexxel) in sub-populations of patients with hypertension. Both amlodipine/benazepril and verapamil sustained release /trandolapril have several published trials supporting efficacy in patients with type 2 diabetes, patients with moderate to severe hypertension, and African Americans. Direct comparisons of BP lowering effects in the sub-populations are difficult, due to differences in study design.

Effect on proteinuria: The verapamil CCB component of verapamil sustained release/ trandolapril physiologically decreases resistance of the afferent renal arteriole, which reduces glomerular pressure and proteinuria. DHP CCBs do not have this effect on the afferent arteriole. Evidence from one large clinical trial showed that a combination of verapamil with trandolapril over a 3 year period prolonged the time to onset of microalbuminuria in patients with type-2 diabetes and hypertension.

Cardiovascular Outcomes: There are no published trials with felodipine/enalapril showing a benefit of the drug in reducing cardiovascular outcomes. There are no completed trials with amlodipine/benazepril assessing cardiovascular outcomes; two ongoing trials are assessing cardiovascular mortality/morbidity (ACCOMPLISH trial) and progression to overt nephropathy (GUARD). There are no published trials assessing the efficacy of the specific Tarka formulation at reducing cardiovascular outcomes. Although a regimen comprised of verapamil sustained release and trandolapril used as add-on therapy showed a reduction in all-cause death, non-fatal myocardial infarction, and non-fatal stroke (INVEST trial), this open label trial did not show a difference in outcomes between a regimen of CCB and ACE inhibitor vs. beta blocker and diuretic. The INVEST trial did not randomize patients prospectively to the combination, thus cannot be used to support efficacy of the specific Tarka formulation in reducing cardiovascular outcomes.

Clinical Efficacy Conclusion: The Committee concluded that there is insufficient evidence to suggest that the BP lowering effects of the ACE/CCB combos differ significantly. The formulations of amlodipine/benazepril and verapamil sustained release/trandolapril have shown efficacy in treating sub-populations of patients with hypertension; there is no data with Lexxel. Clinical trials assessing cardiovascular outcomes with the combination products Lexxel, amlodipine/benazepril and verapamil sustained release/trandolapril have not been conducted, but there is some evidence of benefit with the individual components.

c) Safety and Tolerability:

Serious Adverse Effects: Verapamil sustained release/trandolapril is contraindicated for use in patients with impaired cardiac contractility (e.g. severe left ventricular dysfunction, SBP < 90 mm Hg), due to the verapamil component. All three ACE/CCB combos are contraindicated for use in patients with a history of angioedema to any ACE inhibitor.

Common Adverse Effects: The safety profiles of the ACE/CCB combos are reflected by their individual CCB components. The products containing a DHP CCB (amlodipine/benazepril and felodipine/enalapril) commonly causes edema and headache, while the non-DHP CCB (verapamil sustained release/trandolapril) more commonly causes dyspnea, fatigue, and constipation. Comparison of the product labeling between amlodipine/benazepril and felodipine/enalapril do not suggest major differences in the incidence of edema, headache, or dizziness.

Discontinuations due to Adverse Effects: Pooled data from clinical trials was used to compare the products in terms of the percentage of patients discontinuing therapy due to

adverse events. For felodipine/enalapril, 2.8% of patients discontinued treatment vs. 1.3% with placebo, most commonly due to headache. The percentage of patients discontinuing therapy with amlodipine/benazepril was 4%, vs. 3% with placebo, most commonly due to edema. The discontinuation rate with verapamil sustained release/trandolapril was 2.6% vs. 1.9% with placebo, most commonly due to dyspnea and fatigue.

Safety and Tolerability Conclusion: The DoD P&T Committee concluded that the discontinuation rate due to adverse events appears similar between the three ACE/CCB combos, based on pooled analysis from placebo controlled trials. The non-DHP component of verapamil sustained release/trandolapril imparts unique risks of impaired cardiac contractility. There is no evidence that amlodipine/benazepril and felodipine/enalapril differ markedly in adverse event profiles.

d) Other Factors - Adherence/Persistence with antihypertensive therapy: For the purposes of this review, the measure used to define persistence is the medication possession ratio, which is calculated based on the daily possession of drugs. There are no published trials with felodipine/enalapril or verapamil sustained release/trandolapril showing improved rates of patient persistence. Data from two studies (one published, the other in abstract form) using pharmacy claims databases reported medication possession ratios ranging from 81%-88% with patients continuously refilling prescriptions for amlodipine/benazepril, compared to 69%-73.8% for regimens containing an ACE inhibitor and CCB administered as separate components.

Conclusion for Other Factors (Adherence/Persistence): Two database claims studies suggest that patient persistence with amlodipine/benazepril is improved by 7%-22%, compared to regimens containing an ACE inhibitor and CCB administered as separate components.

2) *Other Miscellaneous Antihypertensive Agents:* The Committee evaluated the other miscellaneous antihypertensive agents by considering the place in therapy of the drugs in national hypertension guidelines, significant usage for conditions other than hypertension, existing MHS utilization, and adverse effect profiles. The Committee also specifically evaluated the relative clinical effectiveness of clonidine tablets vs. clonidine patch.

a) Clonidine oral tablets vs. Clonidine transdermal patches: The JNC VII guidelines recommend clonidine as a second or third line choice for treating hypertension, due to adverse effects. Clonidine is frequently used for off-label indications, including treatment of menopausal symptoms, smoking cessation, pediatric behavioral problems, and alcohol or opiate withdrawal symptoms. Clonidine tablets require twice daily to three times a day dosing, and there is a high risk of rebound hypertension, if the tablets are abruptly discontinued. The clonidine patches are changed weekly and are associated with a lower risk of rebound hypertension, since plasma levels of drug slowly decline over a one-week period when the patch is removed. Other benefits of transdermal clonidine include that it is frequently used in patients with swallowing difficulties (e.g. stroke patients), its use can potentially improve compliance in patients requiring several drugs for BP control, and that its use can simplify the medication regimen in patients requiring several antihypertensive drugs. In the entire MHS, approximately 20,000 prescriptions for clonidine tablets are dispensed monthly, compared to 5,000 prescriptions for clonidine patches.

b) Remaining miscellaneous antihypertensive agents in the class: The remaining miscellaneous antihypertensive drugs in the class include hydralazine, minoxidil, methyldopa, guanabenz, guanfacine, prazosin, reserpine, guanadrel, guanethidine, and

mecamylamine. All of these drugs are available in generic formulations and some no longer have marketed proprietary formulations (e.g. reserpine, guanethidine). Utilization of these drugs in the MHS is low (<5,000 prescriptions dispensed in fiscal year 2005), with the exception of hydralazine (40,000 Rxs), prazosin (22,000 Rxs), methyldopa (13,000 Rxs), and minoxidil (12,000 Rxs). Some of these products have been available for several decades; including reserpine, mecamylamine, hydralazine, methyldopa, and guanethidine, thus rigorously conducted clinical trials are not available.

Place in therapy: JNC VII guidelines support use of methyldopa, hydralazine, minoxidil, reserpine, and guanfacine as antihypertensive drugs, although clinical use is often limited due to tolerability issues. Methyldopa is commonly used for treating hypertension in pregnant patients, due to long-term studies supporting its safety. Hydralazine also has a role in treating symptoms of heart failure in patients who are intolerant of or who have contraindications to use of ACE inhibitors. Guanfacine is also utilized in the setting of pediatric patients with behavioral problems. Guanabenz is rarely used clinically (<500 Rxs dispensed in the MHS in fiscal year 2005), as it requires twice daily dosing and has bothersome side effects. Minoxidil is an option for patients with stage 2 hypertension (SBP 160-179 / DBP 100-109 mm Hg) who have not responded to conventional antihypertensive drug regimens. Reserpine has evidence from randomized controlled trials that it reduces cardiovascular mortality and morbidity (VA trials, SHEP trials). Use of prazosin as an antihypertensive agent has fallen into disfavor, based on the results of the ALLHAT trial that showed an increased risk of development of heart failure in patients receiving the alpha blocker doxasozin. Guanadrel, guanethdine, and mecamylamine are rarely used today.

Adverse Effects: The use of the other miscellaneous antihypertensive agents has largely been replaced by other drugs (e.g. ACE inhibitors, diuretics, CCBs, angiotensin receptor blockers, beta blockers) due to their side effect profiles. Hydralazine may cause drug-induced systemic lupus erythematosus. Minoxidil can cause hypertrichosis; and fluid retention and reflux tachycardia are frequent problematic effects. Common adverse effects of methyldopa, guanabenz and guanfacine include fluid retention, sedation, lethargy, postural hypotension, dizziness, dry mouth and headache. First-dose syncope is a risk with prazosin and other alpha blockers. Clinical use of reserpine is limited due to nasal stuffiness and the perception of increased risk of depression. Orthostatic hypotension is an issue with guanadrel and guanethidine, as is diarrhea, and sexual dysfunction. Postural hypotension is a limiting side effect of mecamlyamine. Other effects of mecamylamine due to its ganglionic blockading properties include tachycardia, mydriasis, paralytic ileus, syncope, and urinary retention.

COMMITTEE RECOMMENDATION: *Overall clinical effectiveness conclusion for the miscellaneous antihypertensive agents:* The Committee concluded that: (1) for lowering blood pressure, there is no evidence that any one ACE/CCB combo is more effective relative to another; (2) there is more evidence to support the use of amlodipine/benazepril and verapamil sustained release/trandolapril in sub-populations of patients with hypertension than felodipine/ enalapril; (3) there is insufficient evidence to conclude that any one ACE/CCB combo is superior to another for reducing risk of cardiovascular outcomes in patients with hypertension; (4); the safety/tolerability profiles of the ACE/CCB combos are primarily dictated by the CCB component; (5) there is no evidence to suggest that amlodipine/benazepril or felodipine/ enalapril would be superior to the other in terms of safety/tolerability. Verapamil sustained release/trandolapril has unique safety issues, due to the verapamil component; (6) persistence rates with amlodipine/benazepril may be improved by 7%-22% compared to the individual

agents administered together; (7) transdermal clonidine is not a candidate for non-formulary designation on the UF due to its unique niche in several patient sub-groups and lower risk of rebound hypertension upon drug discontinuation; (8) Use of the remaining miscellaneous antihypertensive drugs is limited by bothersome tolerability profiles, however, several drugs maintain unique roles for treating hypertension and non-cardiovascular conditions.

COMMITTEE ACTION: The Committee voted (16 for, 0 opposed, 1 absent; 1 abstain) to accept the clinical effectiveness conclusion as stated above.

B. Miscellaneous Antihypertensives UF Relative Cost Effectiveness: The P&T Committee evaluated the relative cost-effectiveness of the miscellaneous antihypertensive agents in relation to safety, tolerability, effectiveness, and clinical outcomes of the other agents in the class. Information considered by the P&T Committee included but was not limited to sources of information listed in 32 CFR 199.21(e) (2).

As with the relative clinical effectiveness evaluation, the primary focus of the relative cost-effectiveness presentation was limited to the combination antihypertensives (amlodipine/benazepril, felodipine/enalapril, verapamil/trandolapril) and clonidine patches. The DoD P&T Committee concluded that the other agents listed in the class, as previously described, should be maintained on the UF given their generic availability, low utilization, and low cost.

To determine the relative cost effectiveness of the miscellaneous antihypertensive agents, two separate economic analyses were performed, a pharmacoeconomic analysis and BIA.

A cost analysis was performed to compare clonidine patches and clonidine tablets. The comparison of cost was based on the point-of-service adjusted total weighted average cost per day of treatment. As expected, the results of the cost-analysis revealed that clonidine patches were significantly more costly compared to clonidine tablets.

Two different types of pharmacoeconomic analysis could have been performed to determine the cost-effectiveness of the combination antihypertensive agents within this therapeutic class. One alternative was to use cost-minimization to compare the combination antihypertensives to their respective agents given separately solely based on cost. However, this alternative would have neglected to account for the primary potential benefit of combination products, improved patient compliance with medication therapy. Therefore, to account for the potential differences in relative clinical effectiveness, a CEA was performed based on the results of three observational studies examining compliance with combination antihypertensives.

The observational studies included two studies that examined compliance with the combination product amlodipine/benazepril and another study that examined compliance with combination ACE/hydrochlorothiazide (HCTZ) products (enalapril/HCTZ and lisinopril/HCTZ). These studies revealed increased compliance ranging from 7% to 20% with the combination antihypertensives compared to the respective agents given separately. For purposes of the CEA, the increased compliance associated with combination antihypertensive products was assumed to be 10%. To determine the relative cost-effectiveness of the combination products, two simple cost-effectiveness decision models were constructed, one comparing the DHP/ACE combination products (amlodipine/benazepril and felodipine/enalapril) to their respective agents given separately and another comparing the verapamil/ACE combination product (verapamil/trandolapril) to its respective agents given separately. The cost used in the model was the total cost of drug treatment for one-year. The outcome/effect was ‘days of treatment.’

Theoretically, 'days of treatment' is a surrogate indicator of compliance. Likewise, compliance with drug therapy theoretically results in overall improved blood pressure control.

The results from the CEAs are as follows:

- DHP/ACE combination
  - The two agents given separately were more cost-effective compared to Lexxel (felodipine/enalapril) and Lotrel (amlodipine/benazepril). However, the incremental cost-effectiveness ratio was relatively low, indicating that the combination products may be a cost-effective alternative therapy.
- Verapamil/ACE combination
  - The two agents given separately were more cost-effective compared to Tarka (verapamil/trandolapril). For this comparison, the incremental cost-effectiveness ratio was relatively high, indicating that the combination product is not a cost-effective alternative therapy.

The results of the CEAs were subsequently incorporated into a BIA. A BIA accounts for other factors and costs associated with a potential decision to recommend that one or more agents be classified as non-formulary, such as: market share migration, cost reduction associated with non-formulary cost shares, and medical necessity processing fees. The goal of the BIA was to assist the Committee in determining which group of miscellaneous antihypertensive best met the majority of the clinical needs of the DoD population at the lowest cost to the MHS. Based on the BIA results and other clinical and cost considerations, the Committee agreed that a group of miscellaneous antihypertensive agents that included: clonidine patches and amlodipine/ benazepril best achieved this goal when compared to other combination groups of miscellaneous antihypertensive agents, and thus were determined to be more cost-effective relative to other combination groups.

Conclusion: The P&T Committee, based upon its collective professional judgment, voted (16 for, 0 opposed, 1 abstention, 1 absent) to accept the miscellaneous antihypertensive cost-analysis presented by the PEC. The P&T Committee concluded that felodipine/enalapril and verapamil/trandolapril were not cost-effective relative to the other miscellaneous antihypertensive agents. Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of the miscellaneous antihypertensive agents, and other relevant factors, the P&T Committee recommended that felodipine/enalapril and verapamil/trandolapril be classified as non-formulary under the UF. The P&T Committee also recommended that clonidine tablets, clonidine patches, amlodipine/ benazepril, hydralazine, minoxidil, methyldopa, guanabenz, guanfacine, reserpine, guanadrel, guanethidine, and mecamylamine be classified as formulary on the UF.

COMMITTEE ACTION: The P&T Committee, based upon its collective professional judgment, voted 11 for, 4 opposed, 2 abstention, 1 absent) to recommend that felodipine/ enalapril and verapamil/trandolapril be classified as non-formulary under the UF, with clonidine tablets, clonidine patches, amlodipine/benazepril, hydralazine, minoxidil, methyldopa, guanabenz, guanfacine, reserpine, guanadrel, guanethidine, and mecamylamine remaining on the UF.

C. Miscellaneous antihypertensive agents Medical Necessity Criteria. The P&T Committee concluded that because the only miscellaneous antihypertensive agents classified as non-formulary under the UF are the combination agents felodipine/enalapril and verapamil/

trandolapril, and because the individual components of both of these agents are available separately on the UF, only two of the five general medical necessity criteria could potentially apply. Therefore, based on the clinical evaluation of felodipine/enalapril and verapamil/ trandolapril and conditions for establishing medical necessity for a non-formulary medication provided in the UF rule, the following medical necessity criteria may apply:

1) Use of a formulary pharmaceutical agent is contraindicated, and the use of a non-formulary agent is not contraindicated.

2) The patient previously responded to the non-formulary pharmaceutical agent and changing to a formulary pharmaceutical agent would incur an unacceptable clinical risk.

COMMITTEE ACTION: The DoD P&T Committee voted (15 for, 0 opposed, 1 abstained, 2 absent) to accept the miscellaneous medical necessity criteria.

D. Miscellaneous Antihypertensive Agents UF Implementation Period: The Committee recommended an effective date no later than the first Wednesday following a 60-day implementation.

COMMITTEE ACTION: The DoD P&T Committee voted (16 for, 0 opposed, 0 abstained, 2 absent) to recommend an implementation period of 60 days.

E. Miscellaneous Antihypertensive Agents Basic Core Formulary (BCF) Review and Recommendations. The P&T Committee had previously determined that at least one but no more that two miscellaneous antihypertensive agents would be added to the BCF based on the clinical and cost effectiveness reviews. As a result of the clinical and economic evaluations presented, the P&T Committee recommended that amlodipine/benazepril, hydralazine and clonidine tablets be added to the BCF.

Conclusion: Lotrel (amlodipine /benazepril), hydralazine and clonidine tablets were recommended for inclusion on the BCF.

COMMITTEE ACTION: The P&T Committee voted (16 for, 0 opposed, 1 abstained, 1 absent) to include Lotrel (amlodipine /benazepril), hydralazine and clonidine tablets on the BCF

8. GAMMA-AMINOBUTYRIC ACID (GABA)-ANALOG DRUG CLASS REVIEW

A. GABA-Analogs Relative Clinical Effectiveness: The DoD P&T Committee evaluated the relative clinical effectiveness of the GABA-analogs marketed in the US: gabapentin (Neurontin and various generics), pregabalin (Lyrica), and tiagabine (Gabitril). Information regarding the safety, effectiveness, and clinical outcome of these drugs was considered. Although gabapentin, pregabalin, and tiagabine are all FDA indicated as adjunctive therapy (added to other antiepileptic drugs) in the treatment of partial seizures, the Committee's review focused primarily on the use of these agents for the treatment of various types of neuropathic pain. The clinical review included, but was not limited to the requirements stated in the UF Rule, 32 CFR 199.21.

1) Efficacy

a) Endpoints: The primary efficacy measure used in the clinical trials was pain experienced by the patients during the previous 24 hours, rated on an 11-point numerical scale (0= no pain; 10= worst possible pain). The primary efficacy parameter was the change in the mean daily pain

score from baseline to the study end; the proportion of patients responding to therapy was a secondary outcome. A >50% reduction in mean pain scores between baseline and study end are considered relevant. Numbers needed to treat (NNT), defined as the number of patients needed to be treated with the drug to result in one patient obtaining a >50% reduction in mean pain score, were then calculated to give a measure of the effect size.

b) Efficacy of GABA analogs for treatment of pain associated with diabetic peripheral neuropathy (DPN):

Place in Therapy: Guidelines from the American Diabetes Association recommend gabapentin and pregabalin and other therapies as initial therapy for the treatment of pain associated with DPN. There is no preference stated for gabapentin or pregabalin in the guidelines. The guidelines do not mention tiagabine.

Clinical Trials for DPN-related pain: There are no head-to-head clinical trials comparing pregabalin with gabapentin for DPN-related pain, and there are no clinical trials evaluating efficacy of tiagabine for this condition. The Committee reviewed the following trials evaluating the use of the GABA-analogs in DPN: one comparative trial of gabapentin vs. amitriptyline; one active controlled trial of pregabalin and amitriptyline vs. placebo; a Cochrane review of four placebo controlled trials with gabapentin; and three placebo controlled trials with pregabalin.

In the comparative trial of gabapentin (900-1800 mg/day) vs. amitriptyline (25-75 mg/day), both treatments resulted in significant reductions in mean pain score from baseline; there was no difference between the two drugs at study endpoint. This trial was limited by small patient enrollment (N=28). In the active controlled trial of pregabalin (600 mg/day) and amitriptyline (75mg/day) vs. placebo, pregabalin did not differ from placebo in the change in mean pain score from baseline or in the proportion of patients achieving at least a 50% decrease in mean pain score at endpoint. These endpoints reached statistical significance when amitriptyline was compared to placebo. Direct comparisons of the efficacy of pregabalin vs. amitriptyline were not conducted in the trial. Overall, treatment with pregabalin 600 mg/d (200 mg three times a day) was no more effective than placebo in the treatment of DPN-related pain in this study.

A Cochrane review of four placebo controlled trials enrolling 281 patients that evaluated the efficacy of gabapentin for DPN pain favored gabapentin [relative risk 2.21 (95% confidence interval 1.65, 2.96)]. The gabapentin doses ranged from 900-3600 mg/day. Overall, 64% of patients improved with gabapentin compared to 28% with placebo. The combined NNT for effectiveness of gabapentin in DPN compared to placebo was 2.9.

The results of the three double-blinded, placebo controlled trials evaluating pregabalin in DPN were reported to the Committee. In two of the three trials, patients were excluded if they had not previously responded to gabapentin doses >1200 mg/day. Pregabalin in doses of 100 mg three times a day (300 mg/day) and 200 mg three times a day (600 mg/day) resulted in statistically significant improvements in the mean pain score at endpoint and in the proportion of patients obtaining at least a 50% reduction in pain score from baseline compared to placebo. The mean pain score at endpoint was 1.26 to 1.45 points lower with pregabalin (300 mg/day and 600 mg/day doses, respectively) than placebo. The percentage of patients responding to pregabalin 300 mg/day ranged from 40% to 46%; the percentage of responders to pregabalin 600 mg/day ranged from 39% to 48%, while the placebo responder rate was 15%. Although 600 mg/day was evaluated in these trials, the product labeling for pregabalin does not recommend doses above 300 mg/day for DPN, as doses of 600 mg/day do not provide greater

benefit. The NNT with pregabalin to achieve a 50% reduction in mean pain score at endpoint ranged from 3.4 to 4.0 for the three studies.

DPN Conclusion: Based on the primary efficacy measures of change in mean pain score at baseline, the percentage of patients responding to therapy, and the NNT, the Committee concluded that there is no evidence to suggest that gabapentin or pregabalin is superior to the other in treating pain associated with DPN, when the individual results from the placebo controlled trials are compared. There are no trials evaluating efficacy of tiagabine in pain due to DPN.

c) Efficacy of GABA analogs for treatment of pain associated with post-herpetic neuralgia (PHN):

Place in therapy: Practice guidelines endorsed by the American Academy of Neurology for the treatment of pain in patients with PHN give a Level A, class I recommendation (strongest evidence for efficacy) to gabapentin and pregabalin. First-line options for the treatment of PHN included gabapentin, pregabalin, lidocaine patch, tricyclic antidepressants and controlled release morphine or oxycodone. The guideline does not give a preference to either pregabalin or gabapentin for the treatment of PHN-related pain, and does not mention tiagabine.

Clinical Trials for PHN pain: There are no head to head clinical trials comparing pregabalin with gabapentin for treatment of pain in patients with PHN. There are no trials evaluating efficacy of tiagabine for PHN-related pain. The Committee evaluated two placebo controlled trials with gabapentin, and three placebo controlled trials with pregabalin for this pain syndrome.

Two double-blind placebo controlled trials compared gabapentin vs. placebo for the treatment of pain associated with PHN. Gabapentin doses ranging from 600 mg three times a day to 900 mg three times a day were evaluated in the two trials. In both trials, patients receiving gabapentin had a statistically significant reduction in mean daily pain score at study end, compared to placebo. The mean pain score at endpoint was 2.1 points lower with gabapentin (all doses) than placebo. In the first trial, 43% of patients receiving gabapentin 900 mg three times a day rated their pain as much improved vs. 12.1% with placebo. In the second trial, the responder rate was 14% with placebo, 32% with gabapentin 600 mg three times a day and 34% with gabapentin 800 mg three times a day.

A Cochrane review of the two placebo controlled trials discussed earlier (enrolling 563 patients) that evaluated the efficacy of gabapentin for PHN pain favored gabapentin [relative risk 2.50 (95% confidence interval 1.80, 3.48)]. Overall, 43% of patients improved with gabapentin compared to 17% with placebo. The combined NNT from these two studies for effectiveness compared to placebo was 2.9.

Three double-blind placebo controlled trials evaluated pregabalin for the treatment of pain associated with PHN. In two of the three trials, patients were excluded if they had not previously responded to gabapentin doses >1200 mg/day. Twice a day dosing of pregabalin was used in one trial, while a three times a day regimen was used in the remaining two trials; doses ranged from 150 mg/day to 600mg/day. All pregabalin doses resulted in significant reductions in mean pain scores compared to placebo. The mean pain score at endpoint was 0.88 to 1.79 points lower with pregabalin (all doses) than placebo. The percentage of patients responding to pregabalin 150 mg/day ranged from 26% to 27%, the percentage of responders to pregabalin 300 mg/day ranged from 27% to 28%, the percentage of responders to pregabalin 600 mg/day ranged from 38% to50%, while the placebo responder rate ranged from 8% to 10%.

The NNT with pregabalin to achieve a 50% reduction in mean pain score at endpoint ranged from 3.3 to 6.3 in the three studies, depending on the dose of pregabalin.

PHN Conclusion: Based on the primary efficacy measures of change in mean pain score at baseline, the percentage of patients responding to therapy, and the NNTs, the Committee concluded that there is no evidence to suggest that gabapentin or pregabalin is superior to the other in treating pain associated with PHN, when the individual results from the placebo controlled trials are compared. There are no trials evaluating efficacy of tiagabine in pain due to PHN.

d) Efficacy of GABA analogs for other neuropathic pain syndromes:

Clinical Trials: The P&T Committee evaluated two trials assessing the efficacy of gabapentin, and one trial assessing the efficacy of tiagabine in other types of neuropathic pain syndromes. Gabapentin was evaluated in doses up to 2.4 g/day in 305 patients with a variety of different types of neuropathic pain syndromes, including complex regional pain syndrome, PHN, radiculopathy, and post laminectomy. The authors reported there was an overall significant difference in mean pain score favoring gabapentin over placebo, however there was no significant difference between gabapentin and placebo at weeks 7 and 8 (the differences at weeks 1,3,5,6 were significant). When gabapentin was compared to placebo in 19 patients with post-amputation limb pain, gabapentin was significantly better than placebo at study endpoint. The effect of tiagabine in painful neuropathy was studied in a 4-week, open-label, non-placebo-controlled pilot trial in 17 adults. Overall pain indices tended to decline, but results did not reach statistical significance for tiagabine vs. placebo, given the high and dropout rate (only 8 patients completed the study).

Other Neuropathic Pain Syndromes Conclusions: The Committee concluded that gabapentin demonstrated modest clinical efficacy for other neuropathic pain syndromes, based on two placebo controlled trials. No conclusion can be made concerning the efficacy of tiagabine for neuropathic pain due to limited evidence (one poorly designed study and overall lack of trials evaluating the efficacy of tiagabine for neuropathic pain). Pregabalin has not been evaluated in other types of neuropathic pain syndromes.

e) Efficacy of GABA Analogs for Treatment of Partial Seizures:

Place in Therapy: A report endorsed by the American Academy of Neurology and the American Epilepsy Society assigned both gabapentin and tiagabine Level A recommendations (highest recommendation) as adjunctive therapy for partial seizures. There was no mention of pregabalin due to publication of the guideline prior to FDA approval.

Clinical Trials: Gabapentin, pregabalin, and tiagabine have all been evaluated in the adjunctive treatment of epilepsy in placebo controlled trials. There are no head to head trials comparing efficacy of one GABA-analog to another in seizure disorders. The results of one meta-analysis conducted with gabapentin and tiagabine, and three double-blinded placebo controlled trials with pregabalin support efficacy of all three agents in patients with epilepsy, based on the endpoint of 50% reduction in seizure frequency.

Partial Seizures Conclusions: The committee concluded that gabapentin, pregabalin, and tiagabine demonstrate clinical efficacy for adjunctive treatment of partial seizures. Since the GABA analogs are added onto regimens comprised of other antiepileptic drugs, there is no evidence to suggest clinical superiority of any GABA agent over another.

Overall efficacy conclusion: The Committee concluded that there is no evidence of superiority of either gabapentin or pregabalin for treatment of pain associated with DPN or PHN. Efficacy of gabapentin for other types of neuropathic pain syndromes appears modest, but there is no efficacy evidence for pregabalin in other types of neuropathic pain. There is insufficient evidence to make conclusions regarding the efficacy of tiagabine in DPN, PHN, or other types of neuropathic pain syndromes.

2) Safety and Tolerability: The Committee assessed the comparative safety and tolerability of gabapentin, pregabalin, and tiagabine including rare but serious adverse effects, common adverse effects, potential for drug interactions, and safety of use in special populations.

Serious Adverse Effects:
All three GABA analogs (gabapentin, pregabalin, and tiagabine) should be gradually tapered when therapy is discontinued, to minimize the potential for increased seizure frequency. Post-marketing reports have linked tiagabine with new onset seizures and status epilepticus in patients who did not have epilepsy. There are reports of sudden unexplained death in patients with epilepsy taking gabapentin or tiagabine, however, it is unknown whether the unexplained deaths were a direct result of gabapentin or tiagabine therapy. Tiagabine has been associated with cognitive/neuropsychiatric events such as impaired concentration, speech and language problems, confusion and fatigue. Pregabalin has been associated with creatine kinase elevations and three reports of rhabdomyolysis in premarketing clinical trials.

Common Adverse effects:
The most commonly reported side effects associated with gabapentin, pregabalin and tiagabine include dizziness, somnolence, and asthenia. These adverse effects appear to be dose related, and tend to decrease over time. Based on clinical trial experience, tiagabine appears more commonly associated with nervousness and tremor, while gabapentin and pregabalin are associated the weight gain, dizziness, somnolence and peripheral edema.

Due to differences in study design for the placebo controlled trials and the lack head to head trials, comparisons of adverse event rates between the GABA analogs are difficult. In general, clinical trials using flexible dosing regimens and slow titration schedules result in fewer patients dropping out of the trial and lower adverse event rates than trials incorporating fixed dosing regimens and quick titration schedules.

A comparison of the product labeling for all three GABA analogs lists the following adverse events, which have been placebo-adjusted. Peripheral edema: 8.3% with gabapentin, and 9% with pregabalin; an incidence is not provided in the tiagabine package insert. Dizziness: 28% with gabapentin, 21% with pregabalin, and 27% with tiagabine. Somnolence: 21.4% with gabapentin, 12% with pregabalin, and 12% with tiagabine.

Numbers needed to harm (NNH) is another way of measuring adverse events and for the purpose of this review was defined as any adverse effect leading to patient withdrawal from a study. NNH could be calculated for two of the trials assessing pain in PHN. For gabapentin, the NNH was 11.2; for pregabalin, the NNH was 3.7. Although the NNH is smaller with pregabalin, possibly indicating a less tolerable drug, the titration period with pregabalin was more rapid (over 1 week) compared to the gabapentin trial (over 4 weeks). A longer titration period may have led to a more favorable NNH in the gabapentin trial. When the NNHs were calculated from a clinical trial evaluating pregabalin for treatment of DPN and PHN in both fixed and flexible doses, the NNH was 10.7 with the flexible dosing regimen, and 5.8 with the fixed dosing regimen. The flexible dosing regimen incorporated a longer titration schedule than

with the fixed dose, which could possibly account for the more favorable NNH with the flexible dosing.

Drug Interactions:

Gabapentin and pregabalin are not metabolized by hepatic CYP450 enzymes, thus are not associated with significant drug interactions. Tiagabine is primarily metabolized by CYP450 and is highly protein bound, thus drug interactions have been reported with concomitant usage with other anticonvulsant drugs (carbamazepine, phenytoin, phenobarbital, primidone).

Special populations:
Renal Impairment: Gabapentin and pregabalin are both renally eliminated, and both drugs require dosage reductions with decreasing renal function. Reductions in gabapentin and pregabalin dosages may be required in patients who have age related compromised renal function.

Hepatic Impairment: Patients with impaired liver function may require reduced initial and maintenance doses of tiagabine or a longer dosing interval compared to patients with normal hepatic function.

Pregnancy: All three GABA analogs are rated as pregnancy category C, and should be used during pregnancy only if the potential benefit justifies the potential risk.

Overall Safety and Tolerability Conclusion: The Committee concluded withdrawal seizures occurring with sudden discontinuation of therapy have been reported with all three GABA analogs. Tiagabine is associated with serious adverse events, including neuropsychiatric and cognitive effects and development of seizures in patients who did not previously have epilepsy. Dizziness and somnolence are the most commonly reported adverse effects with pregabalin and gabapentin, while tremors and nervousness are more commonly reported with tiagabine. Indirect comparisons, based on NNH and the percentage of patients discontinuing therapy due to adverse effects, show only minor differences in tolerability between gabapentin and pregabalin. Tiagabine has a greater drug interaction potential compared to gabapentin and pregabalin, due to hepatic metabolism. Both gabapentin and pregabalin require dose adjustment in patients with renal dysfunction.

3) Other Factors:
FDA Approved indications: Gabapentin and pregabalin are both FDA-approved for treating pain associated with PHN. Pregabalin is the sole agent in the class approved for treating pain associated with DPN, however, controlled clinical trial data support the efficacy of gabapentin. Gabapentin, pregabalin, and tiagabine are all approved as adjunctive therapy in seizure disorders.

Controlled Substance Class: Pregabalin is the only GABA-analog that is a schedule V controlled substance. In clinical studies, following abrupt or rapid discontinuation of pregabalin, some patients reported symptoms of insomnia, nausea, headache, or diarrhea, suggestive of dependence. Due to the schedule V status, no more than 5 refills can be obtained in a 6-month period.

Use in Pediatrics: Gabapentin is approved in for use as an anticonvulsant in patients as young as three years old. Tiagabine is approved for use in patients as young as 12 years old for treatment of epilepsy. Pregabalin has not been studied in pediatric patients.

Pharmacokinetics: Gabapentin exhibits non-linear pharmacokinetics; as the dose of gabapentin is increased, bioavailability decreases. In contrast, pregabalin exhibits linear pharmacokinetics, and the oral bioavailability of pregabalin is > 90% independent of dose. However, a linear dose response has not resulted in significantly improved pain relief with pregabalin administered at higher doses (600mg/d) vs. lower doses (300 mg/d). In fact, the manufacturer of pregabalin does not recommend greater than 300 mg/d for DPN because 600 mg/d pregabalin has not been proven to significantly improve pain scores compared to 300 mg/d, and greater than 600 mg/d for PHN.

Frequency of Dosing and Titration Schedules: Pregabalin can be dosed twice daily for treatment of pain associated with PHN, while gabapentin requires three times a day dosing. For pain associated with DPN, both pregabalin and gabapentin require three times a day dosing. Twice a day dosing of pregabalin in DPN-related pain is not recommended by the manufacturer, as twice daily dosing did not show significant differences in efficacy as compared to placebo in unpublished trials available from the FDA. The dosage initiation schedule for pregabalin is less complex and requires a shorter time period than the dosage titration recommended with gabapentin. Statistical improvements in mean pain score in clinical trials have occurred within 1-2 weeks of initiation of both gabapentin pregabalin therapy.

Provider Opinion: A survey of DoD providers ranked gabapentin first in terms of clinical efficacy for neuropathic pain, due to more personal clinical experience, compared to tiagabine and pregabalin. Pregabalin was ranked second in terms of clinical efficacy, primarily due to lack of clinical experience, but providers did prefer ease of titration and twice daily dosing in PHN. The majority of providers' therapeutic strategy would include a trial of gabapentin first, followed by pregabalin if therapy with gabapentin was not successful. Tiagabine was rarely used in neuropathic pain, and if chosen, it was preferred as adjunctive therapy to other treatments for neuropathic pain, not as an alternative to gabapentin or pregabalin. All three drugs (gabapentin, pregabalin, and tiagabine) were considered therapeutically interchangeable for use in patients with partial seizures.

Other Factors Conclusions: The Committee concluded that pregabalin is the only GABA-analog that has restrictions in prescribing due to its controlled status. The linear pharmacokinetic profile of pregabalin has not resulted in significant improvement in efficacy with higher doses. Pregabalin may potentially have improved patient compliance compared to gabapentin, due to an easier titration schedule and twice a day dosing in patients with PHN. However, three times a day dosing is recommended for pregabalin in patients with DPN. There is no published data evaluating the efficacy of pregabalin in pediatrics.

Overall Clinical Effectiveness Conclusion: The Committee concluded that (1) the efficacy of gabapentin and pregabalin for treating pain associated with either DPN or PHN appears similar; (2) gabapentin is the only GABA-analog that has shown modest efficacy in treating other types of neuropathic pain based on published clinical trials; (3) there is insufficient data regarding the efficacy of tiagabine in patients with neuropathic pain syndromes to make definitive conclusions; (4) there appear to be no major differences in the efficacy of gabapentin, pregabalin, or tiagabine for the use an adjunctive treatment of partial seizures; (5) the safety and tolerability profiles of gabapentin and pregabalin are more favorable compared to tiagabine; (6) there appear to be only minor differences in the tolerability profiles of gabapentin and pregabalin, when evaluating the incidence of somnolence, dizziness, and peripheral edema; (7) there are minor differences in other factors between the drugs, including use in pediatrics, pharmacokinetic profiles, titration schedules, onset of effect, and controlled substance status.

Overall the Committee agreed that based on clinical usefulness alone, there is no basis for classifying any of the GABA-analog as non-formulary.

COMMITTEE ACTION: The DoD P&T Committee voted (16 for, 0 opposed, 1 abstain, 1 absent) to accept the clinical effectiveness conclusion as stated above.

B. Relative CEA: In considering the relative cost-effectiveness of pharmaceutical agents in this class, the P&T Committee evaluated the costs of the agents in relation to the safety, effectiveness, and clinical outcomes of the other agents in the class. Information considered by the P&T Committee included but was not limited to sources of information listed in 32 CFR 199.21(e)(2). A CEA was used to determine the relative cost-effectiveness of agents within the GABA-analog therapeutic class. A Monte Carlo simulation was performed using data from three well designed randomized controlled trials of pregabalin and gabapentin in diabetic peripheral neuropathy and post-herpetic neuralgia. Flexible dose (average 378 mg) and fixed dose (600 mg) pregabalin were compared to daily gabapentin doses of 600, 900, 1200, 1800 and 2400 mg. Costs used in the model were the total weighted average cost per day of treatment across all points of service in the MHS. The principal outcome of interest was the mean reduction in weekly pain scores at the 12th week.

Results of the CEA showed gabapentin at doses of up to 2400 mg to be the most cost effective GABA-analog drug in the treatment of neuropathic pain with the lowest average cost per patient over twelve weeks of treatment, and no clinically significant differences in outcomes.

The results of the above analyses were then incorporated into a BIA, which accounted for other factors and costs associated with a potential decision regarding formulary status of GABA-analog drugs within the UF. These factors included: market share migration, cost reduction associated with non-formulary cost shares, medical necessity processing fees, and switch costs. The results of the BIA further confirmed the results of the CEA. Gabapentin was found to be the most cost-effective GABA-analog drug overall in the treatment of neuropathic pain.

Conclusion: The P&T Committee concluded that gabapentin was the more cost effective GABA-analog drug for the treatment of neuropathic pain. The cost-effectiveness of tiagabine was also considered, and it was determined that nothing would be gained clinically or economically by making tiagabine non-formulary.

COMMITTEE ACTION: The P&T Committee agreed (16 for, 0 opposed, 0 abstained, 2 absent) with the relative CEA of the GABA-analog drugs presented.

Based on the results of the two analyses, the P&T Committee concluded that pregabalin was much more costly, and had similar relative clinical effectiveness compared to gabapentin in both neuropathic pain and partial seizures. Tiagabine also had similar relative clinical effectiveness in partial seizures as compared to gabapentin and pregabalin. However, due to its low utilization, and small, static market share, it was felt that tiagabine contributed minimally to the amount spent in this drug class. Taking into consideration the conclusions from the relative clinical effectiveness and the relative cost effectiveness determinations for the GABA-analog drugs, and other relevant factors, the P&T Committee recommended (14 for, 2 opposed, 0 abstained, 2 absent) that pregabalin be classified as non-formulary under the UF, with gabapentin and tiagabine remaining on the UF.

C. GABA analogs UF Medical Necessity Criteria: Based on the clinical evaluation of the GABA analogs and conditions for establishing medical necessity for a non-formulary

medication provided in the UF rule, the P&T Committee concluded that the following general medical necessity criteria would apply for these agents:

1) Use of formulary agents is contraindicated, and the use of pregabalin is not contraindicated.

2) The patient has experienced or is likely to experience significant adverse effects from the formulary agents, and the patient is expected to tolerate pregabalin.

3) Treatment with formulary agents has resulted in a therapeutic failure, and the patient is expected to respond to pregabalin.

4) The patient previously responded to the pregabalin and changing to a formulary agent would incur an unacceptable clinical risk.

COMMITTEE ACTION: The DoD P&T Committee voted (15 for, 1 opposed, 0 abstained, 2 absent) to accept the GABA-analog medical necessity criteria.

D. GABA-analog UF Implementation Period: The Committee recommended an effective date no later than the first Wednesday following a 60-day implementation.

COMMITTEE ACTION: The DoD P&T Committee voted (15 for, 0 opposed, 0 abstained, 3 absent) to recommend an implementation period of 60 days.

E. GABA-analog BCF Review and Recommendations: The P&T Committee reviewed the GABA analogs recommended for inclusion on the UF to select the BCF GABA analog.

Gabapentin is currently included on the BCF. From a clinical and economic standpoint, all strengths and formulations of gabapentin are rational selections for the BCF. Gabapentin is the highest utilized GABA-analog in all three points of service (MTF, TRRx, and TMOP), is efficacious in treating a variety of neuropathic pain syndromes, and is now generically available.

Conclusion: The Committee concurred with the recommendations to place all formulations and strengths of gabapentin on the BCF.

COMMITTEE ACTION: The DoD P&T Committee voted (16 for, 0 opposed, 0 abstained, 2 absent) to maintain all formulations and strengths of gabapentin on the BCF.

9. ABBREVIATED CLASS REVIEWS: THIAZOLIDINEDIONES (TZDS), ORAL ANTIEMETIC AGENTS; CONTRACEPTIVE AGENTS

Portions of the clinical reviews were presented to the Committee. The Committee provided expert opinion regarding clinical outcomes of importance for the purpose of developing appropriate cost effectiveness models. Both the clinical and economic analyses of each class will be completed during the May 2006 meeting; no action necessary.

10. ADJOURNMENT

The third day of the meeting adjourned at 1130 hours on February 16, 2006. The dates of the next meeting are May 9 – 11, 2006.

17 November 2005

DECISION PAPER:

NOVEMBER 2005 DoD PHARMACY AND THERAPEUTICS COMMITTEE RECOMMENDATIONS

1. CONVENING

2. ATTENDANCE

3. REVIEW MINUTES OF LAST MEETING

A. Corrections to the minutes: Four committee vote counts were incorrectly recorded in the minutes of August 2005 DoD Pharmacy and Therapeutics (P&T) meeting. Corrections are as follows:

1) Item 8a. T*he P&T Committee concluded that all ACEIs are similar in terms of safety and tolerability profiles and in efficacy for hypertension.* The recorded vote of: (16 for, 0 against, 0 abstained, 1 absent) CORRECTED TO: (15 for, 0 against, 1 abstained, 1 absent)

2) Item 9a: *The P&T Committee voted to accept the clinical effectiveness conclusions presented for the calcium channel blocker class.* The recorded vote of: (16 for, 0 against, 0 abstained, 1 absent) CORRECTED TO: (14 for, 2 against, 0 abstained, 1 absent)

3) Item 9b: *The P&T Committee voted to accept the cost effectiveness conclusions presented for the calcium channel blocker class.* The recorded vote of: (17 for, 0 against, 0 abstained, 0 absent) CORRECTED TO: (14 for, 2 against, 0 abstained, 1 absent)

4) Item 9c: *The P&T Committee voted to accept the medical necessity criteria for the calcium channel blocker class.* The recorded vote of: (16 for, 0 against, 0 abstained, 1 absent) CORRECTED TO: (14 for, 2 against, 0 abstained, 1 absent)

4. INTERIM DECISIONS/ADMINISTRATIVE ISSUES

5. ITEMS FOR INFORMATION

6. REVIEW OF RECENTLY APPROVED AGENTS

The P&T Committee was briefed on six new agents that had been approved by the FDA, of which five have been introduced to the U.S. market since the August 2005 meeting. None of the medications fall into drug classes already reviewed by the P&T Committee, therefore Uniform Formulary (UF) consideration was deferred until the corresponding drug class reviews are completed. The Committee did review one new drug for quantity limits. Mometasone furoate oral inhaler is a new corticosteroid for asthma that has a unique deliver device (Asmanex Twisthaler 220 mcg). The device delivers 200 mcg per actuation, and is available in several sizes providing 14 inhalations (for institutional use), 30 inhalations, 60 inhalations (for patients requiring 1 dose/day) or 120 inhalations (for patients requiring more than 1 dose/day). There are quantity limits for the other inhaled corticosteroids; therefore, quantity limits for Asmanex Twisthaler are recommended.

COMMITTEE ACTION: The P&T Committee voted (17 for, 0 against, 1 abstained, 1 absent) to recommend that mometasone furoate oral inhaler 220 mcg (Asmanex Twisthaler) have

quantity limits of 120 inhalations per 30-days (retail pharmacy network), or 360 inhalations per 90-days (TRICARE Mail Order Pharmacy (TMOP)), consistent with the limits imposed with other inhaled corticosteroids (see paragraph 6 on page 14 of P&T Committee minutes for rationale and summary of PA criteria).

*Director, TMA, Decision***:** ☑Approved ☐ Disapproved

Approved, but modified as follows:

7. PRIOR AUTHORIZATION (PA) REQUIREMENT FOR MECASERMIN (INCRELEX) INJECTION

The Committee agreed that a PA was needed for mecasermin (Increlex) subcutaneous injection due to potential confusion with other growth products and misuse potential.

***COMMITTEE ACTION*:** Based on the need for careful patient selection to ensure safety and effectiveness, the P&T Committee recommended (17 for, 0 against, 1 abstained, 1 absent) that PA be required for mecasermin (see paragraph 7 on pages 14 – 15 of P&T Committee minutes for rationale and summary of PA criteria).

*Director, TMA, Decision***:** ☑Approved ☐ Disapproved

Approved, but modified as follows:

***COMMITTEE ACTION*:** The Committee recommended (17 for, 0 against, 1 abstained, 1 absent) that the PA for mecasermin should have an effective date no later than the first Wednesday following a 30-day implementation period. The implementation period will begin immediately following the approval by the Director, TRICARE Management Activity (TMA) (see paragraph 7 on page 15 of P&T Committee minutes).

*Director, TMA, Decision***:** ☑Approved ☐ Disapproved

Approved, but modified as follows:

8. QUANTITY LIMITS

A. Etanercept (Enbrel) – Etanercept was initially approved as a 25 mg twice-weekly injection for the treatment of RA and was available only as a 25-mg vial in sealed packages containing 4 vials (2 weeks supply for RA, psoriatic arthritis, or ankylosing spondylitis or 1-2 weeks supply for psoriasis). Dosing recommendations for etanercept have changed to allow weekly dosing for all indications, and etanercept recently became available as a 50 mg/mL pre-filled syringe, which is now the preferred method of dosing. The current days supply limit of a 4-week supply in retail, a 6-week supply in the TMOP program, and up to a 6-week supply at military treatment facilities (MTFs) (based on instructions for use on the prescription) is

problematic for the 50 mg/mL pre-filled syringes, which are supplied in sealed packages containing 4 syringes.

The Committee agreed that, given the cost of etanercept and the existence of similar quantity limits for other biologics for the treatment of RA and/or psoriasis, a day's supply limit should be retained, but adjusted to 8 weeks supply in mail order and MTFs to allow for dispensing of whole packages.

***COMMITTEE ACTION*.** The Committee voted (16 for, 0 opposed, 2 abstained, 1 absent) to recommend changing the quantity limits for etanercept (Enbrel) subcutaneous injection to a four-week supply in retail, an eight-week supply in the TMOP program, and up to an eight-week supply at MTFs, based on instructions for use on the prescription (see paragraph 8A on pages 15 – 16 of P&T Committee minutes for rationale and summary of quantity limits).

*Director, TMA, Decision***:** ☑Approved ☐ Disapproved

Approved, but modified as follows:

B. Zolmitriptan (Zomig) – The current quantity limit for zolmitriptan tablets and orally disintegrating tablets (Zomig, Zomig-ZMT) is 8 tablets per 30 days or 24 tablets per 90 days. Currently, zolmitriptan tablets are available in blister packs of 3 or 6 tablets. The current quantity limit for zolmitriptan nasal spray, which is packaged in boxes of 6 unit-dose nasal spray units, is 12 unit-doses per 30 days or 36 unit-doses per 90 days. The Committee agreed that the quantity unit for zolmitriptan tablets should be increased to be consistent with the quantity limit for the nasal spray and to allow for dispensing of whole packages of zolmitriptan tablets.

***COMMITTEE ACTION*.** The Committee voted (16 for, 1 opposed, 1 abstained, 1 absent) to recommend changing the quantity limit for zolmitriptan tablets and orally disintegrating tablets (Zomig, Zomig-ZMT) to 12 tablets per 30 days or 36 tablets per 90 days (see paragraph 8B on page 16 of P&T Committee minutes for rationale and summary of quantity limits).

*Director, TMA, Decision***:** ☑Approved ☐ Disapproved

Approved, but modified as follows:

9. ALZHEIMER'S DRUG CLASS REVIEW. ACETYLCHOLINESTERASE INHIBITOR AND N-METHYL D-ASPARTATE (NMDA) RECEPTOR ANTAGONIST

The P&T Committee evaluated the relative clinical effectiveness and cost effectiveness of the acetylcholinesterase inhibitors donepezil (Aricept), rivastigmine (Exelon), galantamine (Razadyne), and tacrine (Cognex), and the NMDA receptor antagonist memantine (Namenda) used to treat the cognitive symptoms of Alzheimer's disease. Together these drugs account for approximately $65M annually in Military Health System (MHS) drug class expenditures.

A. COMMITTEE ACTION: The P&T Committee voted (17 for, 0 against, 1 abstained, 1 absent) that for the purposes of the UF clinical review, with the exception of tacrine, none of the acetylcholinesterase inhibitors have a significant clinically meaningful therapeutic advantage in terms of safety, effectiveness, or clinical outcome over the other acetylcholinesterase inhibitors; and that memantine has a place in therapy due to its indication for treatment of dementia in moderate to severe Alzheimer's disease. The P&T Committee agreed that among the acetylcholinesterase inhibitors, tacrine differed significantly in terms of safety due to its potential to cause hepatic injury.

Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations for the acetylcholinesterase inhibitors and memantine, and other relevant factors, the P&T committee recommended (10 for, 6 against, 2 abstained, 1 absent) that tacrine be classified as non-formulary under the UF, with memantine, donepezil, rivastigmine, and galantamine remaining on the UF (see paragraphs 9A – B on pages 16 – 20 of P&T Committee minutes for rationale).

*Director, TMA, Decision***:** ☑Approved ☐ Disapproved

Approved, but modified as follows:

B. COMMITTEE ACTION: Based on the clinical evaluation of tacrine and the conditions for establishing medical necessity for a non-formulary medication provided for in the UF rule, the P&T Committee recommended (17 for, 0 against, 1 abstained, 1 absent) medical necessity criteria for tacrine. (See paragraph 9C on page 20 of P&T Committee minutes for criteria).

*Director, TMA, Decision***:** ☑Approved ☐ Disapproved

Approved, but modified as follows:

C. COMMITTEE ACTION: The P&T Committee recommended (17 for, 0 against, 1 abstained, 1 absent) an effective date no later than the first Wednesday following a 90-day implementation period. The implementation period will begin immediately following the approval by the Director, TMA (see paragraph 9D on page 20 of P&T Committee minutes for rationale).

*Director, TMA, Decision***:** ☑Approved ☐ Disapproved

Approved, but modified as follows:

D. COMMITTEE ACTION: Based on the relative clinical and cost effectiveness analyses, the P&T Committee voted (17 for, 0 against, 1 abstained, 1 absent) to recommend donepezil as the Extended Core Formulary agent (see paragraph 9E on pages 20 – 21 of P&T Committee minutes for rationale).

*Director, TMA, Decision***:** ☑Approved ☐ Disapproved

Approved, but modified as follows:

10. NASAL CORTICOSTEROIDS FOR ALLERGIC RHINITIS DRUG CLASS REVIEW

The P&T Committee evaluated the relative clinical effectiveness and cost effectiveness of the nasal corticosteroids used to treat allergic rhinitis. Six agents were considered in the review, beclomethasone dipropionate (Beconase AQ, Vancenase AQ, and Vancenase AQ DS), budesonide (Rhinocort AQ), flunisolide (Nasarel), fluticasone propionate (Flonase), mometasone furoate (Nasonex), and triamcinolone acetonide (Nasacort AQ). The nasal corticosteroids rank in the top 20 in terms of MHS drug class expenditures at $60.2M annually.

A. COMMITTEE ACTION: The P&T Committee concluded (17 for, 0 against, 1 abstained, 1 absent) that no one nasal corticosteroid has a significant clinically meaningful therapeutic advantage in terms of safety, effectiveness, or clinical outcome over the other nasal corticosteroids.

The cost analysis showed that flunisolide, fluticasone propionate, and mometasone furoate are more cost effective than the other nasal corticosteroids. The budget impact analysis also concluded that flunisolide, fluticasone propionate, and mometasone furoate represent the best value to DoD.

Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations for the nasal corticosteroids, and other relevant factors, the P&T Committee recommended (17 for, 0 against, 1 abstained, 1 absent), that beclomethasone dipropionate (Beconase AQ, Vancenase AQ, Vancenase AQ DS), budesonide (Rhinocort AQ), and triamcinolone acetonide (Nasacort AQ) be classified as non-formulary under the UF, and that flunisolide (Nasarel), fluticasone propionate (Flonase), and mometasone furoate (Nasonex) be classified as formulary under the UF (see paragraphs 10A – B on pages 21 – 25 of P&T Committee minutes for rationale).

*Director, TMA, Decision***:** ☑Approved ☐ Disapproved

Approved, but modified as follows:

B. COMMITTEE ACTION: Based on the clinical evaluations of beclomethasone dipropionate, budesonide, and triamcinolone acetonide and the conditions for establishing medical necessity for a non-formulary medication provided for in the UF rule, the P&T Committee recommended (17 for, 0 against, 1 abstained, 1 absent) medical necessity criteria

for the nasal corticosteroids. (See paragraph 10C on page 25 of P&T Committee minutes for criteria).

*Director, TMA, Decision***:** ☑Approved ☐ Disapproved

Approved, but modified as follows:

C. COMMITTEE ACTION: Due to the relatively low number of patients that will be affected by this formulary action, the P&T Committee recommended (17 for, 0 against, 1 abstained, 1 absent) an effective date no later than the first Wednesday following a 90-day implementation period. The implementation period will begin immediately following the approval by the Director, TMA (see paragraph 10D on page 25 of P&T Committee minutes for rationale).

*Director, TMA, Decision***:** ☑Approved ☐ Disapproved

Approved, but modified as follows:

D. COMMITTEE ACTION: Based on the relative clinical and cost effectiveness analyses, the P&T Committee voted (17 for, 0 against, 1 abstained, 1 absent) to recommend fluticasone propionate as the Basic Core Formulary (BCF) agent (see paragraph 10E on page 25 of P&T Committee minutes for rationale).

*Director, TMA, Decision***:** ☑Approved ☐ Disapproved

Approved, but modified as follows:

11. ANTIDEPRESSANTS GROUP 1 (AD1) DRUG CLASS REVIEW

The P&T Committee evaluated the relative clinical effectiveness and cost effectiveness of the antidepressant medications, with the exception of the monoamine oxidase inhibitors and tricyclic antidepressants. The AD1s accounted for $290 million in MHS expenditures in FY05. Individual agents in the AD1 drug class are listed below.

- *Selective Serotonin Reuptake Inhibitors (SSRIs)* – citalopram (generics, Celexa); escitalopram (Lexapro); fluoxetine (generics, Prozac); fluoxetine 90-mg delayed release capsules (Prozac Weekly); fluoxetine in special packaging for the treatment of premenstrual dysphoric disorder (PMDD) (Sarafem); fluvoxamine (generics); paroxetine immediate release (generics, Paxil, Pexeva); paroxetine controlled release (Paxil CR); and sertraline (Zoloft)
- *Serotonin Norepinephrine Reuptake Inhibitors (SNRIs)* - venlafaxine (Effexor, Effexor XR); duloxetine (Cymbalta)

- *Norepinephrine Dopamine Reuptake Inhibitors (NDRIs)* - bupropion immediate and sustained release (generics, Wellbutrin, Wellbutrin SR); bupropion extended release (Wellbutrin XL)
- *Alpha-2 antagonists* – mirtazapine (generics, Remeron)
- *Serotonin modulators* – nefazodone (generics); trazodone (generics, Desyrel)

A. COMMITTEE ACTION: The P&T Committee concluded (17 for, 0 against, 1 abstained, 1 absent) that: 1) the AD1s offer similar efficacy in treating major depressive disorder (MDD) with the exception of limited data supporting slightly greater efficacy with venlafaxine compared to the SSRIs and with escitalopram compared to citalopram; 2) FDA approval of fluoxetine for MDD in children, and broad usefulness of paroxetine and sertraline in psychiatric conditions other than MDD were considered clinical advantages; 3) with the exception of venlafaxine, where nausea is a greater problem, there are little data to support a substantial difference among AD1s with respect to patient tolerability; however, adverse effect profiles do differ across AD1s; 4) bupropion, mirtazapine, nefazodone, and trazodone appear to have a lower risk of sexual dysfunction compared with SSRIs and SNRIs; 5) fluvoxamine, fluoxetine, paroxetine and duloxetine have a higher potential for drug interactions than citalopram, escitalopram, sertraline, and venlafaxine; 6) the likelihood of discontinuation syndrome with the SSRIs corresponds with half-life (shortest half-life = greatest risk). fluvoxamine > paroxetine > sertraline > escitalopram > citalopram > fluoxetine, and venlafaxine may be associated with more discontinuation symptoms than SSRIs; while discontinuation symptoms appear rare with bupropion; 7) rare but serious adverse effects are associated with duloxetine (recent case reports of hepatotoxicity), bupropion (seizure), nefazodone (hepatotoxicity), mirtazapine (agranulocytosis), and trazodone (priapism); and 8) drugs of concern in specific patient populations include duloxetine (hepatic insufficiency, substantial alcohol use, liver disease, narrow angle glaucoma), paroxetine (recent epidemiological evidence of increased risk in pregnancy), and bupropion (avoid in patients with increased seizure risk).

Relative Cost Effectiveness Analysis: Differences in efficacy, safety, and tolerability among the AD1s were incorporated into two separate cost effectiveness analyses (CEAs). The first CEA was based on the results obtained via a multi-attribute utility theory (MAUT) analysis, which included differences between agents in clinical outcome, evidence and/or FDA-approved indications supporting use for psychiatric and non-psychiatric conditions other than MDD, such as generalized anxiety disorder (GAD), posttraumatic stress disorder (PTSD), diabetic peripheral neuropathic pain (DPNP), as well as usefulness in the pediatric population, and safety/tolerability factors such as risk of drug interactions, use in pregnancy, contraindications, potential for rare but serious adverse events, and risk of sexual dysfunction. The second CEA (CEA-Response) was based on findings reported in the DoD Pharmacoeconomic Center's clinical review and the Oregon Health & Science University's Drug Class Review on Second Generation Antidepressants as part of the Drug Effectiveness Review Project. This CEA assessed the costs and outcomes of treatment for MDD during the acute phase of treatment.

Based on the results of the two analyses, the P&T Committee concluded (17 for, 0 against, 1 abstained, 1 absent) that: 1) fluoxetine 90-mg delayed release capsules (Prozac Weekly) and fluoxetine in special packaging for treatment of PMDD (Sarafem) were greater than seven-fold more costly, and had similar relative clinical effectiveness compared to generic fluoxetine; 2)

sertraline had equal (CEA-Response) or slightly greater (CEA-MAUT) relative clinical effectiveness, but was significantly more costly compared to fluoxetine (however, sertraline is projected to go generic in June 2006); 3) escitalopram was shown to have lower overall relative clinical effectiveness (CEA-MAUT) compared to fluoxetine, but potentially greater relative clinical effectiveness in the treatment of MDD (CEA-Response) compared to citalopram; however, at a significantly greater cost; 4) the CEA-MAUT and CEA-Response both showed that paroxetine and paroxetine CR had similar relative clinical effectiveness, but paroxetine CR was significantly more costly compared to paroxetine; 5) venlafaxine was shown to have greater overall relative clinical effectiveness (CEA-MAUT) and greater relative clinical effectiveness in the treatment of MDD (CEA-Response) compared to duloxetine for a similar cost; and 6) bupropion XL was shown to have greater overall relative clinical effectiveness (CEA-MAUT) but similar relative clinical effectiveness in the treatment of MDD (CEA-Response) compared to bupropion SR at a significantly greater cost.

Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations for the antidepressants, and other relevant factors, the P&T Committee recommended (12 for, 5 against, 1 abstained, 1 absent) that escitalopram (Lexapro), fluoxetine 90-mg delayed release capsules (Prozac Weekly), fluoxetine in special packaging for PMDD (Sarafem), paroxetine controlled release (Paxil CR), duloxetine (Cymbalta), and bupropion extended release (Wellbutrin XL) be classified as non-formulary under the UF, with citalopram, fluoxetine, fluvoxamine, paroxetine immediate release, sertraline, venlafaxine, venlafaxine extended release, nefazodone, trazodone, bupropion immediate and sustained release, and mirtazapine remaining on the UF. In addition, the P&T Committee recommended that existing quantity limits for fluoxetine 90-mg delayed release capsules (Prozac Weekly) of 4 capsules per 30 days, 12 capsules per 90 days be continued. (See paragraphs 11 A – B on pages 26 – 40 of the P&T Committee minutes for criteria).

*Director, TMA, Decision***:** ☑Approved ☐ Disapproved

Approved, but modified as follows:

B. COMMITTEE ACTION: Based on the clinical evaluation of the AD1s and the conditions for establishing medical necessity for a non-formulary medication provided for in the UF rule, the P&T Committee recommended (16 for, 0 against, 1 abstained, 2 absent) medical necessity criteria for escitalopram (Lexapro), fluoxetine 90-mg delayed release capsules (Prozac Weekly), fluoxetine in special packaging for PMDD (Sarafem), paroxetine controlled release (Paxil CR), duloxetine (Cymbalta), and bupropion extended release (Wellbutrin XL). (See paragraph 11C on pages 40 – 41 of P&T Committee minutes for rationale).

*Director, TMA, Decision***:** ☑Approved ☐ Disapproved

Approved, but modified as follows:

C. COMMITTEE ACTION: Because a substantial number of patients are currently receiving non-formulary AD1s, and the need to carefully assess and monitor patients taking this class of medication, the P&T Committee recommended (16 for, 0 against, 1 abstained, 2 absent) an effective date no later than the first Wednesday following a 180-day implementation period. The implementation period will begin immediately following the approval by the Director, TMA (see paragraph 11D on page 41 of P&T Committee minutes for rationale).

*Director, TMA, Decision***:** ☑Approved ☐ Disapproved

Approved, but modified as follows:

D. COMMITTEE ACTION: Based on the relative clinical and cost effectiveness analyses, the P&T Committee voted (17 for, 0 against, 1 abstained, 1 absent) to recommend fluoxetine (excluding Prozac Weekly and Sarafem, which are non-formulary), citalopram, sertraline, trazodone, and bupropion sustained release as the BCF agents (see paragraph 11E on pages 41 – 42 of P&T Committee minutes for rationale).

*Director, TMA, Decision***:** ☑Approved ☐ Disapproved

Approved, but modified as follows:

12. ORAL MACROLIDE/KETOLIDE DRUG CLASS REVIEW

The P&T Committee evaluated the relative clinical effectiveness and cost effectiveness of the macrolide/ketolide class of antibiotics. All forms of oral erythromycin (salts and base) were considered in addition to the oral forms of azithromycin, clarithromycin, and telithromycin. Zmax, a 2-gram extended release suspension form of azithromycin was also considered, but was evaluated separately from the other forms of azithromycin. The macrolide/ketolide class of antibiotics ranks 31st in terms of MHS drug class expenditures at $40.7M annually.

A. COMMITTEE ACTION: The P&T Committee concluded (17 for, 0 against, 1 abstained, 1 absent) that although the macrolide/ketolide agents have significant overlapping antimicrobial activity within the class and with agents in other antibiotic classes, there are some minor differences in terms of safety, effectiveness, and clinical outcomes between the agents. Advantages of a good safety profile, ease of dosing, provider acceptability, and generic availability made azithromycin stand out as a preferred agent in this class. Erythromycin also stood out as a preferred agent in this class due to its many FDA indications, safety, generic availability and familiarity among providers.

Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations for the macrolide/ketolide class of antibiotics, and other relevant factors, the P&T Committee recommended (17 for, 0 against, 1 abstained, 1 absent) that Zmax and telithromycin be classified as non-formulary under the UF, with all oral forms of azithromycin (except Zmax), all forms of clarithromycin, and all oral forms of erythromycin

remaining on the UF (see paragraphs 12 A – B on pages 42 – 48 of P&T Committee minutes for rationale).

*Director, TMA, Decision***:** ☑Approved ☐ Disapproved

Approved, but modified as follows:

B. COMMITTEE ACTION: Based on the clinical evaluations of telithromycin and the Zmax formulation of azithromycin and the conditions for establishing medical necessity for a non-formulary medication provided for in the UF rule, the P&T Committee recommended (17 for, 0 against, 1 abstained, 1 absent) medical necessity criteria for Zmax and telithromycin (see paragraph 12C on pages 48 – 49 of P&T Committee minutes for criteria).

*Director, TMA, Decision***:** ☑Approved ☐ Disapproved

Approved, but modified as follows:

C. COMMITTEE ACTION: Because of the acute nature of this class of medications and the relatively low number of beneficiaries that would be affected by this formulary action, the P&T Committee recommended (16 for, 1 against, 1 abstained, 1 absent) an effective date no later than the first Wednesday following a 60-day implementation period. The implementation period will begin immediately following the approval by the Director, TMA (see paragraph 12D on page 49 of P&T Committee minutes for rationale).

*Director, TMA, Decision***:** ☑Approved ☐ Disapproved

Approved, but modified as follows:

D. COMMITTEE ACTION: Based on the relative clinical and cost effectiveness analyses, the P&T Committee voted (17 for, 0 against, 1 abstained, 1 absent) to recommend azithromycin 250mg tablets and at least one form of oral erythromycin base or salt (with selection left to each MTF) as the BCF agents (see paragraph 12E on page 49 of P&T Committee minutes for rationale).

*Director, TMA, Decision***:** ☑Approved ☐ Disapproved

Approved, but modified as follows:

13. ANTI-MUSCARINIC OVERACTIVE BLADDER MEDICATIONS

Portions of the clinical review were presented to the Committee. The Committee provided expert opinion regarding clinical outcomes of importance for the purpose of developing an appropriate cost effectiveness model. Both the clinical and economic analyses will be completed during the February 2006 meeting; no action necessary.

APPENDIX A – TABLE 1. Implementation Status of UF Decisions

APPENDIX B – TABLE 2. Newly Approved Drugs

APPENDIX C – TABLE 3. Abbreviations

DECISION ON RECOMMENDATIONS

Director, TMA, decisions are as annotated above.

Date: January 19, 2005

Department of Defense
Pharmacy and Therapeutics Committee Minutes

17 November 2005

1. CONVENING

The DoD Pharmacy and Therapeutics (P&T) Committee convened at 0800 hours on 15 November 2005 at the DoD Pharmacoeconomic Center (PEC), Fort Sam Houston, Texas.

2. ATTENDANCE

A. Voting Members Present

CAPT Patricia Buss, MC, USN	DoD P& T Committee Chair
CDR Mark Richerson, MSC, USN	DoD P& T Committee Recorder
CDR Bill Blanche, MSC, USN	DoD Pharmacy Programs, TMA
Maj Nicholas Conger, MC	Air Force, Internal Medicine Physician
Maj Michael Proffitt, MC	Air Force, OB/GYN Physician
Lt Col Brian Crownover, MC	Air Force, Physician at Large
Maj Charlene Reith, BSC	Air Force, Pharmacy Officer
LCDR Chris Hyun, MC	Navy, Internal Medicine Physician
LCDR Scott Akins, MC	Navy, Pediatrics Physician
CDR Brian Alexander, MC	Navy, Physician at Large
CAPT David Price, MSC	Navy, Pharmacy Officer
COL Doreen Lounsbery, MC	Army, Internal Medicine Physician
MAJ Roger Brockbank, MC	Army, Family Practice Physician
COL Joel Schmidt, MC	Army, Physician at Large
LTC Peter Bulatao, MS	Army, Pharmacy Officer
CDR Vernon Lew, USPHS	Coast Guard, Pharmacy Officer
CDR Jill Pettit, MSC, USN	Contracting Officer Representative, TRRx
Mr. Joe Canzolino	Department of Veterans Affairs

B. Voting Members Absent

LTC Don DeGroff, MS	Contracting Officer Representative, TMOP

C. Non-Voting Members Present

Lynn T. Burleson	Assistant General Counsel, TMA
Martha Taft	Resource Management Directorate, TMA
Capt Peter Trang, BSC, USAF	Defense Supply Center Philadelphia

D. Non-Voting Members Absent

COL Kent Maneval, MS, USA	Defense Medical Standardization Board

E. Others Present

Col Nacy Misel, BSC, USAF Reserve	IMA DoD Pharmacoeconomic Center
Lt Col David Bennett, BSC, USAF	DoD Pharmacoeconomic Center
Lt Col James McCrary, MC, USAF	DoD Pharmacoeconomic Center
Maj Wade Tiller, BSC, USAF	DoD Pharmacoeconomic Center
CPT Jill Dacus, MC , USA	DoD Pharmacoeconomic Center
CPT Ryan Young, USA	DoD Pharmacoeconomic Center
SFC Daniel Dulak, USA	DoD Pharmacoeconomic Center
Dan Remund	DoD Pharmacoeconomic Center
Shana Trice	DoD Pharmacoeconomic Center
David Bretzke	DoD Pharmacoeconomic Center
Angela Allerman	DoD Pharmacoeconomic Center
Eugene Moore	DoD Pharmacoeconomic Center
Julie Liss	DoD Pharmacoeconomic Center
Elizabeth Hearin	DoD Pharmacoeconomic Center
Dave Flowers	DoD Pharmacoeconomic Center
David Meade	DoD Pharmacoeconomic Center
Harsha Mistry	DoD Pharmacoeconomic Center
Debbie Khachikian	Department of Veterans Affairs

3. REVIEW MINUTES OF LAST MEETING

A. Corrections to the minutes – Four committee vote counts were incorrectly recorded in the minutes of the August 2005 DoD P&T meeting. Corrections are as follows:

1) Item 8a. T*he P&T Committee concluded that all ACEIs are similar in terms of safety and tolerability profiles and in efficacy for hypertension.* The recorded vote of: (16 for, 0 against, 0 abstained, 1 absent) CORRECTED TO: (15 for, 0 against, 1 abstained, 1 absent)
2) Item 9a: *The P&T Committee voted to accept the clinical effectiveness conclusions presented for the calcium channel blocker class.* The recorded vote of: (16 for, 0 against, 0 abstained, 1 absent) CORRECTED TO: (14 for, 2 against, 0 abstained, 1 absent)
3) Item 9b: *The P&T Committee voted to accept the cost effectiveness conclusions presented for the calcium channel blocker class.* The recorded vote of: (17 for, 0 against, 0 abstained, 0 absent) CORRECTED TO: (14 for, 2 against, 0 abstained, 1 absent)
4) Item 9c: *The P&T Committee voted to accept the medical necessity criteria for the calcium channel blocker class.* The recorded vote of: (16 for, 0 against, 0 abstained, 1 absent) CORRECTED TO: (14 for, 2 against, 0 abstained, 1 absent)

B. August minutes approval – Dr. William Winkenwerder, Jr., M.D. approved the minutes of the August 2005 DoD P&T Committee on 13 October 2005.

4. INTERIM DECISIONS/ADMINISTRATIVE ISSUES

A. CAPT Buss reported TRICARE Management Activity (TMA) funds in support of travel and lodging for DoD P&T members to attend quarterly meetings have been approved.

5. ITEMS FOR INFORMATION

TMA and DoD PEC staff members briefed the P&T Committee on the following:

A. Beneficiary Advisory Panel (BAP) Briefing: LtCol Bennett briefed the members of the DoD P&T committee regarding the 28 September 2005 BAP meeting. The Committee was briefed on BAP comments regarding DoD P&T Committee's Uniform Formulary (UF) and implementation recommendations.

B. Implementation Status of UF Decisions: PEC staff and TMA briefed the members of the Committee on the implementation status of UF decisions arising from the February, May and August 2005 meetings (see Table 1, Appendix A). The Committee noted that the five drug classes reviewed at the 2005 February and May meetings represent 17% of total Military Health System (MHS) drug spend dollars. These five drug classes plus the four drug classes covered by existing pharmaceutical contracts represent 35% of all MHS drug spend dollars.

6. REVIEW OF RECENTLY-APPROVED AGENTS

The PEC presented clinical information on six new medications approved by the U.S. Food and Drug Administration (FDA). All of the products have been introduced to the U.S. market, with the exception of mecasermin injection (Increlex). (See Table 2, Appendix B). All six medications fall into drug classes not yet reviewed by the DoD P&T Committee; therefore, UF consideration of these products was deferred until drug class reviews are completed.

One of the medications, mometasone furoate oral inhaler (Asmanex Twisthaler), is included as a part of the inhaled corticosteroids drug class, for which there are existing quantity limits. Asmanex Twisthaler provides 200 mcg of mometasone furoate per inhalation, and is available in several sizes, including 14 inhalations (for institutional use), 30 inhalations, 60 inhalations (for patients requiring 1 dose/day) or 120 inhalations (for patients requiring more than 1 dose/day).

COMMITTEE ACTION: The DoD Pharmacy and Therapeutics (P&T) Committee voted (17 for, 0 against, 1 abstained, 1 absent) to recommend that mometasone furoate oral inhaler 220 mcg (Asmanex Twisthaler) have quantity limits of 120 inhalations per 30-days (TRICARE Retail Pharmacy (TRRx) Network), or 360 inhalations per 90-days (TRICARE Mail Order Pharmacy (TMOP) program), consistent with the limits imposed with other inhaled corticosteroids.

7. PRIOR AUTHORIZATION (PA) REQUIREMENT FOR MECASERMIN (INCRELEX) INJECTION

Mecasermin is used for the long-term treatment of growth failure in children with severe primary insulin-like growth factor (IGF)-1 deficiency (primary IGFD) or with growth hormone (GH) gene deletion that have developed neutralizing antibodies to GH. Severe primary IGFD includes patients with mutations in the GH receptor (GHR), post-GHR signaling pathway, and IGF-1 gene defects; these patients are not GH deficient, and therefore cannot be expected to respond adequately to exogenous GH treatment. Mecasermin presents some unique concerns regarding appropriate patient selection, dosing, administration, potential for misuse, and monitoring for possible low blood glucose levels (hypoglycemia), because it has insulin-like hypoglycemic effects. Labeling for mecasermin includes specific recommendations for patient selection. Mecasermin should only be used by patients who have the clinical diagnosis of

severe Primary IGFD and are receiving care from appropriate providers (e.g., pediatric endocrinologist/ nephrologist) on a regular basis. Patients using mecasermin must understand how to adjust mecasermin, and be able to recognize hypoglycemia. Mecasermin is not indicated for use in patients with closed epiphyses (bone growth plates).

***COMMITTEE ACTION*:** Based on the need for careful patient selection to ensure safety and effectiveness, the P&T Committee recommended that a PA be required for mecasermin (17 for, 0 against, 1 abstained, 1 absent). The Committee recommended that the PA should have an effective date no later than the first Wednesday following a 30-day implementation period. The implementation period will begin immediately following the approval by the Director, TMA.

The Committee agreed that the following PA criteria should apply (17 for, 0 against, 1 abstained, 1 absent). PA approvals would be valid for one year.

Coverage is provided for the use of mecasermin as treatment in severe Primary IGFD and in patients who meet all of the following criteria:

- Height standard deviation score $\leq$ -3 and
- Basal IGF-1 standard deviation score $\leq$ -3 and
- Normal or elevated GH
- Are receiving ongoing care under the guidance of a health care provider skilled in the diagnosis and management of patients with growth disorders.
- Thyroid and nutritional deficiencies corrected before initiating mecasermin treatment.
- Have been educated on monitoring and management of hypoglycemia.

Coverage is not provided for patients who:

- Have closed epiphyses (bone growth plates are closed).
- Have active or suspected neoplasia (therapy should be discontinued if evidence of neoplasia develops).
- Have other cases of growth failure (secondary forms of IGF-1 deficiency, such as GH deficiency, malnutrition, hypothyroidism, or chronic treatment with pharmacologic doses of anti-inflammatory steroids).

8. QUANTITY LIMITS

A. Etanercept (Enbrel) – Currently, etanercept (Enbrel) subcutaneous injection is limited to a 4-week supply in retail, a 6-week supply in the TMOP, and up to a 6-week supply at military treatment facilities (MTFs), based on instructions for use on the prescription. No multiple fills for multiple co-pays are allowed in TRRx and TMOP. The purpose of the quantity limit is to decrease potential wastage and excess cost if etanercept is prematurely discontinued.

The current recommended dose of etanercept for adult patients with rheumatoid arthritis (RA), psoriatic arthritis, or ankylosing spondylitis is 50 mg per week; for adult patients with psoriasis 50 mg twice weekly for 3 months, followed by 50 mg weekly as a maintenance dose; and for pediatric patients with juvenile rheumatoid arthritis 0.8 mg/kg weekly, up to a maximum of 50 mg per week. Etanercept was initially approved as a 25 mg twice-weekly injection for the treatment of RA and was available only as a 25-mg vial in sealed packages containing 4 vials (2 weeks supply for RA or 1-2 weeks supply for psoriasis). It recently became available as a 50 mg/mL pre-filled syringe, which is now the preferred method of dosing. The pre-filled syringes are packaged in sealed packages containing 4 syringes, causing difficulty in dispensing a 6-week supply.

The Committee agreed that, given the cost of etanercept and the existence of similar quantity limits for other biologics for the treatment of RA and/or psoriasis, a quantity limit should be retained, but adjusted to an 8-week supply in mail order and MTFs to allow for dispensing of whole packages.

COMMITTEE ACTION: The Committee voted (16 for, 0 opposed, 2 abstained, 1 absent) to recommend changing the quantity limits for etanercept (Enbrel) subcutaneous injection to a 4-week supply in retail, an 8-week supply in the TMOP program, and up to an 8-week supply at MTFs, based on instructions for use on the prescription.

B. Zolmitriptan (Zomig) – The current quantity limit for zolmitriptan tablets and orally disintegrating tablets (Zomig, Zomig-ZMT) is 8 tablets per 30 days, or 24 tablets per 90 days. Based on safety recommendations in triptan labeling, the safety of treating more than 4 migraine attacks in a 30-day period has not been established. Doses of both the tablets and nasal spray can be repeated after two hours if the first dose is ineffective.

Currently, zolmitriptan tablets are available in blister packs of 3 or 6 tablets. Zolmitriptan is also available as a nasal spray, packaged in boxes of 6 unit-dose nasal spray units. The current quantity limit for zolmitriptan nasal spray is 12 unit-doses per 30 days or 36 unit-doses per 90 days.

The Committee agreed that the quantity unit for zolmitriptan tablets should be increased to be consistent with the quantity limit for the nasal spray and to allow for dispensing of whole packages of zolmitriptan tablets.

COMMITTEE ACTION: The Committee voted (16 for, 1 opposed, 1 abstained, 1 absent) to recommend changing the quantity limit for zolmitriptan tablets and orally disintegrating tablets (Zomig, Zomig-ZMT) to 12 tablets per 30 days, or 36 tablets per 90 days.

9. ALZHEIMER'S DRUG CLASS REVIEW. ACETYLCHOLINESTERASE INHIBITORS AND N-METHYL D-ASPARTATE (NMDA) RECEPTOR ANTAGONISTS

A. Alzheimer's Medications Relative Clinical Effectiveness Review: The P&T Committee evaluated the relative clinical effectiveness of all the FDA-approved acetycholinesterase inhibitors and NMDA receptor antagonists available in the U.S. for the treatment of Alzheimer's disease. The Alzheimer's disease therapeutic class was defined as the acetyl-cholinesterase inhibitors: donepezil (Aricept), rivastigmine (Exelon), galantamine (Razadyne) and tacrine (Cognex); and the NMDA receptor antagonist memantine (Namenda). The clinical review included consideration of pertinent information from a variety of sources determined by the P&T Committee to be relevant and reliable, including but not limited to sources of information listed in 32 C.F.R. 199.21(e)(1). The P&T Committee was advised that there is a statutory presumption that pharmaceutical agents in a therapeutic class are clinically effective and should be included on the UF, unless the P&T Committee finds by a majority vote that a pharmaceutical agent does not have a significant, clinically meaningful therapeutic advantage in terms of safety, effectiveness, or clinical outcome over the other pharmaceutical agents included on the UF in that therapeutic class.

During a twelve month period ending July 31, 2005, 69,940 MHS patients were prescribed an acetylcholinesterase inhibitor or NMDA receptor antagonist. This class is now ranked 29th in MHS drug class expenditures at a cost of $65 million annually.

*1.) Efficacy. A*ll acetylcholinesterase inhibitors have FDA-approved indications for the treatment of mild to moderate Alzheimer's disease. The NMDA receptor antagonist

memantine is FDA approved for moderate to severe Alzheimer's disease. As there are no well-designed head-to-head trials comparing the four acetylcholinesterase inhibitors or memantine, the available placebo controlled trials and meta-analyses were reviewed.

Endpoints: Outcome measures used to assess the beneficial effects of the medications used in the treatment of Alzheimer's disease measure functioning in four categories which include cognitive function, global assessment, activities of daily living and behavioral disturbance. The two most consistent outcome measures used in randomized, controlled trials evaluate cognitive function (Alzheimer's Disease Assessment Scale, ADAS-Cog) and global assessment (Clinician's Interview Based Assessment of Change-Plus, CIBIC-Plus). The ADAS is an 11-item scale with scores ranging from 0 (no impairment) to 70 (very severe impairment). On average, untreated patients with moderate AD decline 7 to 11 points per year while treated patients with mild or severe disease decline 0 to 5 points per year. Generally, an improvement of 4 or more points is considered to be clinically meaningful, roughly equivalent to a six-month delay in cognitive decline. In clinical trials, improvement is characterized by a slowing of deterioration as opposed to improvement above baseline.

Mild to moderate Alzheimer's disease: The acetylcholinesterase inhibitors have been studied in mild to moderate Alzheimer's disease. Outcome measures included the ADAS-Cog and the CIBIC-plus. In well-designed, randomized, controlled trials involving donepezil vs. placebo, rivastigmine vs. placebo, galantamine vs. placebo, and tacrine vs. placebo, all of the achetylcholinesterase inhibitors showed statistically significant differences in the primary outcome measures compared to placebo. Systematic reviews by Cochrane, the British National Institute for Clinical Excellence (NICE), the Canadian Coordinating Office of Health Technology Assessment (CCOHTA), and others have found that treatment with these drugs conferred a small clinical benefit when compared to placebo.

Moderate to severe Alzheimer's disease: Memantine is FDA-approved for treatment of moderate to severe Alzheimer's disease. Clinical trials comparing memantine to placebo used the ADAS-Cog and the Severe Impairment Battery (SIB) for primary outcome measures. In all of the trials, memantine showed a statistically and clinically significant improvement over placebo in the primary outcome measures.

Efficacy conclusion: All of the drugs used for Alzheimer's disease show statistically significant changes in cognition rating scores compared to baseline. Whether these results are clinically significant is debatable. There are no direct comparative trials available, but there is no evidence to suggest that any one Alzheimer's disease drug is more efficacious than another, when used according to FDA indications.

2.) Safety/Tolerability:

Serious effects – hepatotoxicity: Tacrine has been shown to cause elevated liver function tests (LFTs) in over 50% of patients, with 7% of patients experiencing LFT elevations greater than 10 times the upper limits of normal. In a major clinical trial, these LFT elevations led to an overall 72% discontinuation rate at the higher dosage range. The FDA requires a black box warning for the possibility of severe liver failure and death, and frequent monitoring of LFTs is mandated for patients using tacrine.

Side effects: Rivastigmine and galantamine are associated with a higher incidence of gastrointestinal (GI) side-effects and consequently require more complex titration than the other cholinesterase inhibitors or memantine. A complex titration schedule possibly affects

the likelihood that patients will adhere to these regimens. In clinical trials of memantine, the rate of patients discontinuing due to side effects was not statistically different from placebo.

Drug interactions: Donepezil and galantamine are metabolized by the CYP 450 enzyme system and thus may be prone to more drug interactions than other agents. However, it should be noted that interactions that increase levels of the Alzheimer's drugs are not generally considered to be clinically significant.

Safety/tolerability conclusion: The P&T Committee agreed that among the acetylcholinesterase inhibitors, tacrine differed significantly in terms of safety due to its potential to cause hepatic injury. While minor differences exist among the other acetylcholinesterase inhibitors and memantine, none were considered significantly different with respect to major contraindications, drug interactions, and adverse drug reactions.

3.) Other Factors:

Titration and dosing frequency: A difference in ease of dosing and dose titration schedules exists among these agents. Donepezil and galantamine extended release are dosed once daily, the other agents are dosed twice daily (galantamine immediate release, rivastigmine and memantine) or four times daily (tacrine). There are no well-designed randomized controlled trials that demonstrate improved outcomes with once daily dosing of these agents, however once daily products have the theoretical advantage of yielding a lower burden on caregivers.

DoD Provider Preferences: In a PEC survey of DoD providers (neurologists, geriatricians, internists, and family practitioners), the majority of respondents favored products with once daily dosing. Most respondents stated that they avoided tacrine because of hepatotoxicity; all expressed a preference for donepezil based on ease of titration and familiarity; most said that they add or switch to memantine when acetylcholinesterase inhibitors failed to provide expected benefit; and most felt that these medications should not be discontinued once they stopped arresting cognitive decline, since patients decline precipitously once these medications were stopped.

Other Factors Conclusion: There is no evidence to suggest clinical superiority of any one Alzheimer's agent based on differences in dosing and titration schedules or DoD provider opinion.

Overall Clinical Effectiveness Conclusion: The P&T Committee concluded that tacrine has less clinical utility than the other acetylcholinesterase inhibitors used in the treatment of the cognitive symptoms of Alzheimer's disease. Furthermore the safety concerns regarding the use of tacrine outweighed any cost benefit that might be obtained by keeping it on the UF. The P&T Committee further concluded that safety considerations for tacrine would support a PA; however, due to the extremely low number of unique utilizers (single digits) any potential problem was felt to be self-limiting. The P&T Committee concluded that all the remaining acetylcholinesterase inhibitors have similar relative clinical effectiveness for treating mild to moderate dementia associated with Alzheimer's disease. The P&T Committee agreed that memantine has a place in therapy for the treatment of moderate to severe dementia associated with Alzheimer's disease. With regard to safety and tolerability, memantine has an adverse event rate similar to placebo.

COMMITTEE ACTION. The P&T Committee voted (17 for, 0 against, 1 abstained, 1 absent) that for the purposes of the UF clinical review, that tacrine possessed a safety disadvantage

relative to other available acetylcholinesterase inhibitors, but that all were similar in terms of effectiveness and clinical outcome, and that memantine has a place in therapy due to its indication for treatment of dementia in moderate to severe Alzheimer's disease.

B. Alzheimer's Drug UF Relative Cost Effectiveness: In considering the relative cost effectiveness of pharmaceutical agents in this class, the P&T Committee evaluated the costs of the agents in relation to the safety, effectiveness, and clinical outcomes of the other agents in the class. Information considered by the P&T Committee included but was not limited to sources of information listed in the Code of Federal Regulations (32 C.F.R. 199.21(e)(2)).

The first step in determining the relative cost effectiveness of the selected agents in this class was to conduct a cost-analysis to calculate the total weighted average cost per day of treatment for each agent. The second step was to conduct the appropriate pharmacoeconomic analysis taking into account the conclusions of the clinical review. Because the clinical review concluded, with the exception of tacrine, that all of the agents within the Alzheimer's drug class had similar relative clinical effectiveness (efficacy, safety and tolerability), a cost-minimization analysis (CMA) was selected. To adjust for the safety issues associated with the use of tacrine, the cost of monitoring liver function tests was added to the drug cost of tacrine in the CMA.

The cost analysis only considered drug costs. The results showed tacrine to be the acetylcholinesterase inhibitor with the lowest total weighted average cost per day of treatment across all points of service (MTF, TRRx, TMOP). The CMA, which considered lab costs for monitoring tacrine, showed that donepezil was the most cost-effective agent when the additional requirement of multiple liver function tests was taken into account.

The results of the above analyses were then incorporated into a budget impact analysis (BIA), which accounted for other factors and costs associated with a potential decision regarding formulary status of Alzheimer's drugs within the UF. These factors included: market share migration, cost reduction associated with non-formulary cost shares, medical necessity processing fees, and switch costs. The results of the BIA further confirmed the results of the CMA. Donepezil was found to be the most cost-effective Alzheimer's drug overall.

Conclusion: The P&T Committee agreed (17 for, 0 against, 1 abstained, 1 absent) with the relative cost effectiveness analysis (CEA) of the Alzheimer's drugs presented. The P&T Committee concluded that the safety concerns regarding the use of tacrine outweighed any cost benefit that might be obtained by keeping it on the UF. Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of the Alzheimer's drugs, the P&T Committee recommended that the status of tacrine be changed from formulary to non-formulary on the UF, with donepezil, rivastigmine, galantamine, and memantine maintaining formulary status on the UF with the formulary cost share. To address the safety concerns of tacrine, a PA for tacrine was initially considered. However, due to the extremely low number of unique utilizers (single digits) currently being treated with tacrine across the MHS, the P&T Committee felt the medical community was adequately aware of the risks associated with tacrine use, and safety concerns were already being appropriately addressed.

COMMITTEE ACTION. The P&T Committee, based upon its collective professional judgment, voted (10 for, 6 against, 2 abstained, 1 absent) to recommend non-formulary status for tacrine, with donepezil, rivastigmine, galantamine, and memantine maintaining formulary status on the UF at the formulary cost share.

C. Alzheimer's Drug UF Medical Necessity Criteria: Based on the clinical evaluation of tacrine, and the conditions for establishing medical necessity for a non-formulary medication provided for in the UF rule, the P&T Committee recommended the following medical necessity criteria for these agents.

1) Use of the formulary cholinesterase inhibitors (donepezil, galantamine, rivastigmine) is contraindicated, and the use of tacrine is not contraindicated.

2) The patient has experienced or is likely to experience significant adverse effects from the formulary acetylcholinesterase inhibitors (donepezil, galantamine, rivastigmine), and the patient is reasonably expected to tolerate tacrine.

3) Use of the formulary acetylcholinesterase inhibitors (donepezil, galantamine, rivastigmine) resulted in therapeutic failure, and the patient is reasonably expected to respond to tacrine (therapeutic failure as outlined on medical necessity form).

4) The patient has previously responded to tacrine, and changing to the formulary acetylcholinesterase inhibitors (donepezil, galantamine, rivastigmine) would incur unacceptable risk.

5) There is no alternative formulary agent.

COMMITTEE ACTION. The P&T Committee voted (17 for, 0 against, 1 abstained, 1 absent) to approve the medical necessity criteria.

D. Alzheimer's Drug UF Implementation Plan: Because of the low number of beneficiaries that would be affected by this formulary action (five patients known to be taking tacrine across the MHS), the P&T Committee recommended an effective date no later than the first Wednesday following a 90-day implementation period. The implementation period will begin immediately following approval by the Director, TMA.

MTFs will not be allowed to have tacrine on their local formularies. MTFs will be able to fill non-formulary requests for this agent only if both of the following conditions are met: 1) the prescription must be written by a MTF provider, and 2) the beneficiary and/or provider must establish medical necessity for these agents. MTFs may (but are not required to) fill a prescription for tacrine written by a non-MTF provider to whom the patient was referred, as long as medical necessity has been established.

COMMITTEE ACTION. The P&T Committee recommended (17 for, 0 against, 1 abstained, 1 absent) an effective date no later than the first Wednesday following a 90 day implementation period. The implementation period will begin immediately following the approval by the Director, TMA.

E. Alzheimer's Drug Extended Core Formulary (ECF) Review and Recommendations. **T**he P&T Committee had previously determined that only one acetylcholinesterase inhibitor would be added to the ECF based on the clinical and cost effectiveness reviews. Additionally, the P&T Committee previously stated that one NMDA inhibitor (memantine) would be considered for addition to the ECF based on a favorable cost effectiveness evaluation. As a result of the economic evaluations presented, the P&T Committee recommended that donepezil be added to the ECF.

Conclusion: Donepezil was recommended for inclusion on the ECF.

COMMITTEE ACTION. The P&T Committee voted (17 for, 0 against, 1 abstained, 1 absent) to add donepezil to the ECF.

10. NASAL CORTICOSTEROIDS DRUG CLASS REVIEW

A. Nasal corticosteroid Relative Clinical Effectiveness Review: The Committee evaluated the relative clinical effectiveness of the six nasal corticosteroids marketed in the U.S.: beclomethasone dipropionate (Beconase AQ, Vancenase AQ and Vancenase AQ DS), budesonide (Rhinocort AQ), flunisolide (Nasarel), fluticasone propionate (Flonase), mometasone furoate (Nasonex), and triamcinolone acetonide (Nasacort AQ). Information regarding the safety, effectiveness, and clinical outcome of these drugs was considered. The clinical review included, but was not limited to the requirements stated in the UF Rule, 32 CFR 199.21.

1) *Efficacy*: All of the nasal corticosteroids are FDA-approved for the treatment of seasonal allergic rhinitis (SAR) and perennial allergic rhinitis (PAR). Endpoints used in clinical trials included patient scoring on the total nasal symptom score (nasal blockage, rhinorrhea, sneezing and nasal itching) or total symptom score (itchy/burning eyes, tearing, redness). Two clinical reviews of seventeen randomized controlled trials evaluating various nasal corticosteroids determined equal efficacy amongst the nasal corticosteroids. Twenty placebo-controlled/head-to-head trials also concluded that nasal corticosteroids were equally effective at equipotent doses at relieving allergic rhinitis symptoms. Possible differences may lie in individual physician/patient preferences and population specific safety concerns.

   Efficacy Conclusion: Multiple clinical reviews over the past two decades suggest comparable efficacy between the nasal corticosteroids at relieving allergic rhinitis symptoms when used in equipotent doses.

2) *Safety and Tolerability*:

   a. Local effects:

      Transient local reactions, such as nasal irritation and stinging, sneezing, dryness, headaches, and occasional sore throat, are the common side effects seen with nasal corticosteroids. All of the aqueous nasal corticosteroid sprays can cause epistaxis, but in clinical trials, the placebo spray also had an appreciable rate of epistaxis. Other, rarely reported local adverse events include nasal septum ulceration and septal perforation. There is no evidence to suggest that one nasal corticosteroid is more likely to cause local adverse effects than another. According to package insert data, approximately 2-3% of patients discontinue a nasal corticosteroid treatment due to adverse events.

   b. Systemic Adverse Events:

      i. *Hypothalmic adrenal axis (HPA) suppression:* HPA-axis suppression is a concern with all corticosteroids (oral, inhaled, and nasal) as it can progress to acute adrenal crisis in all ages. Two separate review articles, one evaluating 19 randomized clinical trials and the other 7 additional randomized clinical trials, found no significant differences between the nasal corticosteroids in suppression of the HPA-axis. The true clinical relevance of nasal corticosteroid use and any resultant significant adrenal gland suppression/adrenal crisis is difficult to ascertain as the trials report changes in surrogate markers (e.g., urinary cortisol excretion, serum

cortisol, or adrenocorticotropin hormone concentration) and are not consistent across testing methods. Placebo-controlled trials show similar HPA-axis suppression between placebo and nasal corticosteroids, as evidenced by reductions in lab values, while comparisons with oral prednisone showed greater suppression than nasal corticosteroids. It is unlikely that the risks of HPA-axis suppression differ among nasal corticosteroids, although theoretically fluticasone propionate and mometasone furoate may confer lower risk due to lower bioavailability than the others.

ii. *Growth retardation:* All inhaled and nasal corticosteroids are required by the FDA to have a warning label in their package inserts regarding the potential risk of growth suppression. Regular monitoring is especially necessary for children receiving multiple corticosteroid therapies, as excessive corticosteroid doses can lead to proven growth suppression. Head-to-head trials and placebo-controlled trials have shown conflicting results among the nasal corticosteroids in outcomes measuring lower leg growth velocity and standing height. Inconsistency across trials in growth measurement and study methodology make it difficult to interpret actual growth suppression and to determine the possible effects of nasal corticosteroids when predicting future pediatric growth velocity. In general, nasal corticosteroids should be used with care in children by titrating to the lowest effective dose so to keep growth suppression to a minimum.

iii. *Cataracts:* A large retrospective evaluation from the UK compared the use of nasal corticosteroids in over 280,000 patients with and without diagnosed cataracts. Over 70% of the patients were solely receiving beclomethasone dipropionate. No increased association was found between nasal steroid use and cataract formation; however, patients receiving chronic oral corticosteroid therapy were found to have an increased frequency of cataract formation. Excessive doses of nasal corticosteroids can lead to rare effects of cataracts. There is insufficient evidence to predict whether one nasal corticosteroid is more likely to cause cataracts than the other.

Overall safety conclusion: Nasal irritation, epistaxis, and rhinorrhea are the most common local adverse events, and are equally likely to occur with any of the nasal corticosteroids. For systemic effects (HPA-axis suppression, growth suppression, and cataract formation), there is no definitive evidence that one nasal corticosteroid is more likely to cause these effects than another. Depending on the severity of allergic rhinitis symptoms, the benefits of nasal corticosteroids may outweigh the risks of systemic adverse effects. According to the package inserts, the risk of systemic effects is increased when higher than normal amounts of nasal corticosteroids are used.

3) *Other Factors:*

a. *Dosing frequency*: Most of the nasal corticosteroid products are marketed for once daily administration. Budesonide, fluticasone propionate, mometasone furoate, and triamcinolone acetonide are dosed once a day, while beclomethasone dipropionate and flunisolide require at least twice to three times daily dosing. Dosing may contribute to patient adherence or patient preference for an individual product. Theoretically, once daily dosing may result in improved patient compliance vs. products requiring multiple daily dosing.

b. *Kinetics/dynamics*: Molecular weight, lipophilicity, and thixotropy are types of pharmacokinetic measures used to differentiate potency between the nasal

corticosteroids. When evaluating potency, varying results have been reported between nasal corticosteroids, as experimental set-ups in the laboratory setting do not conclusively correlate with what providers may witness in their patients. There is no evidence that differences in these kinetic/dynamic parameters are linked to differences in clinical outcomes.

c. *Formulation*: The nasal aerosol formulations of Beconase (beclomethasone dipropionate), Vancenase (beclomethasone dipropionate), and Rhinocort (budesonide) have declined in popularity as physicians and patients have chosen the ease and convenience of use with the newer aqueous nasal formulations (Beconase AQ, Vancenase AQ, Vancenase AQ DS, Rhinocort AQ, Flonase, Nasonex, Nasacort AQ).

d. *Pediatric Populations:* All the nasal corticosteroids are indicated for use in children six years of age or older, but fluticasone propionate is indicated for children down to the age of four years, and mometasone furoate is indicated for use in children as young as two years old.

e. *Pregnancy:* The only nasal corticosteroid with a FDA Category B (low risk in humans) rating is budesonide. This indication was given primarily due to a retrospective epidemiological study reviewing data from three Swedish registries and a pregnancy outcome study (Steroid Treatment and Regular Therapy [START] study) of over 6,000 infants. All the other nasal corticosteroids are rated Category C (risk cannot be ruled out). There is one placebo-controlled human study that focused specifically on the safety and efficacy of maternal nasal corticosteroid (fluticasone propionate) use during pregnancy. There were no differences found between the treatment and placebo groups in pregnancy outcomes. Pregnant patients are still advised to discuss benefit versus risk ratios of nasal corticosteroid use with their OB/GYN provider.

f. *Patient preference/tolerability*: Patient's attitudes toward features such as taste, odor, irritation, and moistness may attribute to adherence of certain nasal corticosteroids. Patient preference may play a role in differentiating between the nasal corticosteroids, but the available clinical data are poor, and no one nasal corticosteroid has proven superior to the others in patient preference trials. More well-designed, head-to-head randomized, controlled trials are needed to support a conclusion that one nasal corticosteroid is superior to another in tolerability or compliance.

Conclusion for Other Factors: Minor differences exist among the agents in terms of frequency of dosing, kinetic/dynamic parameters, pediatric labeling, and use in pregnancy.

Overall Clinical Effectiveness Conclusion: The DoD P&T Committee concluded that: 1) in equipotent doses, the nasal corticosteroids are equally effective at relieving symptoms of allergic rhinitis; 2) in equipotent doses the nasal corticosteroids have similar local side effect profiles; 3) there is a lower risk of systemic adverse effects (HPA-axis suppression, growth retardation, cataract formation) when nasal corticosteroids are used according to labeled dosing instructions; however, there is no evidence that systemic effects are likely to occur more frequently with one agent versus another; 4) products that are dosed once daily may have advantages in terms of patient preference over products requiring multiple daily dosing; 5) minor differences in pharmacokinetic/dynamic factors (thixotropy, molecular weight, lipophilicity) have not translated into differences in clinical outcomes; 6) mometasone furoate is indicated for use in pediatric patients as young as two years of age; 7) budesonide is rated pregnancy category B, while fluticasone propionate has evidence from one trial that pregnancy

outcomes were not adversely affected with use during pregnancy; and 8) there is no clear difference between the nasal corticosteroids in terms of patient preference and tolerability.

COMMITTEE ACTION. The P&T Committee voted (17 for, 0 against, 1 abstained, 1 absent) that, for the purposes of the UF clinical review, none of the nasal corticosteroids have a significant clinically meaningful therapeutic advantage in terms of safety, effectiveness, or clinical outcome over the other nasal corticosteroids.

B. Nasal Corticosteroids Relative Cost Effectiveness: The P&T Committee evaluated the relative cost effectiveness of the agents considering possible differences in safety, tolerability, and effectiveness in accordance with 32 CFR 199.21 (e)(2).

Two separate economic evaluations were performed, a pharmacoeconomic analysis and a BIA. From the proceeding relative clinical effectiveness evaluation, the P&T Committee determined that nasal corticosteroids have similar relative clinical efficacy, but some small differences in terms of dosing frequency, use in pregnancy, use in pediatric populations, and DoD provider preferences. The agents within the nasal corticosteroid therapeutic class were thus shown to differ slightly in relative clinical effectiveness.

The above stated differences in the nasal corticosteroids have not been evaluated in clinical trials for their effect on treatment outcomes. The PEC surveyed DoD medical providers to evaluate their opinion on these difference. The PEC conducted two cost analyses, one analysis with no effectiveness measure, and the second analysis incorporating the results of the survey as an effectiveness measure.

In the first cost analysis of the cost per day of therapy across DoD alone, the results showed that flunisolide was the most effective; budesonide, fluticasone propionate, mometasone furoate and triamcinolone acetonide (not in rank order) were less cost effective; and beclomethasone was not cost effective.

In the second cost analysis of the cost per day of therapy across DoD incorporating the effectiveness measure, the results showed that (all in alphabetical order) flunisolide, fluticasone propionate and mometasone furoate were the most cost effective, and beclomethasone dipropionate, budesonide and triamcinolone acetonide were not cost effective.

Both cost analyses were incorporated into a BIA, to analyze the cost to the DoD under various formulary status configurations, and to estimate the cost of formulary changes to the DoD. The results of the BIA revealed that the best combination of agents to meet DoD's clinical and cost effectiveness goals is the group of formulary agents that included flunisolide, fluticasone propionate, and mometasone furoate. These results matched the results from the cost analysis incorporating the effectiveness measure derived from the survey of DoD providers.

Conclusion: The P&T Committee, based on its collective professional judgment, voted (15 for, 0 opposed, 1 abstained, 3 absent) to accept the nasal corticosteroid CEA presented by the PEC. The P&T Committee concluded that flunisolide, fluticasone propionate, and mometasone furoate had similar cost effectiveness, and that they had greater cost effectiveness than beclomethasone dipropionate, budesonide, or triamcinolone acetonide.

Class Review Conclusion: Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness evaluations, and other relevant factors, the P&T Committee recommended that beclomethasone dipropionate, budesonide, and triamcinolone acetonide be classified as non-formulary under the UF, and that flunisolide, fluticasone propionate, and mometasone furoate be classified as formulary on the UF.

COMMITTEE ACTION: The P&T Committee, based on its collective professional judgment, voted (17 for, 0 opposed, 1 abstained, 1 absent) to recommend formulary status for flunisolide, fluticasone propionate, and mometasone furoate; and non-formulary status for beclomethasone dipropionate, budesonide, and triamcinolone acetonide under the UF.

C. Nasal Corticosteroids UF Medical Necessity Criteria: Based on the clinical evaluation of the nasal corticosteroids and the conditions for establishing medical necessity for non-formulary medications provided for in the UF rule, the P&T Committee concluded that the following general medical necessity criteria would apply for these agents:

1) Use of all formulary nasal corticosteroids (flunisolide, fluticasone propionate, mometasone furoate) is contraindicated, and the use of a nonformulary nasal corticosteroid (beclomethasone dipropionate, budesonide, triamcinolone acetonide) is not contraindicated.
2) The patient has experienced or is likely to experience significant local adverse events (epistaxis, pharyngitis, nasal irritation) from all formulary nasal corticosteroids, and the patient is reasonably expected to tolerate a non-formulary nasal corticosteroid.
3) Use of all the formulary nasal corticosteroids resulted in therapeutic failure, and the patient is reasonably expected to respond to a non-formulary nasal corticosteroid (therapeutic failure as outlined on the medical necessity form).

COMMITTEE ACTION. The P&T Committee voted (17 for, 0 against, 1 abstained, 1 absent) to approve the medical necessity criteria.

D. Nasal corticosteroid UF Implementation Plan: Due to the relatively low number of patients that will be affected by this formulary action, the P&T Committee recommended an effective date no later than the first Wednesday following a 90-day implementation period.

COMMITTEE ACTION: The P&T Committee recommended (17 for, 0 against, 1 abstained, 1 absent) an effective date no later than the first Wednesday following a 90-day implementation period. The implementation period will begin immediately following the approval by the Director, TMA

E. Nasal Corticosteroids Basic Core Formulary (BCF) Review and Recommendations. **T**he P&T Committee reviewed the nasal corticosteroids recommended for inclusion on the UF to select the BCF nasal corticosteroid(s). It had been previously decided that at least one, but no more than two, nasal corticosteroids would be added to the BCF, based on the outcome of a preliminary clinical effectiveness review and DoD needs assessment conducted at the August 2005 P&T Committee meeting.

A cost analysis was performed using prices submitted for BCF status. While flunisolide had a lower cost per day of therapy than fluticasone propionate and mometasone furoate, fluticasone propionate provided the best overall value to DoD, in terms of a competitive price, most preferred dosing frequency (once a day), and overwhelming preference by DoD providers in all but a small subpopulation of DoD patients. The Committee saw no compelling need to have a second agent on the BCF.

Conclusion: The P&T Committee recommended retaining fluticasone on the BCF.

COMMITTEE ACTION: The P&T Committee voted (17 for, 0 opposed, 1 abstained, 1 absent) to recommend fluticasone as the BCF agent.

11. ANTIDEPRESSANTS GROUP 1 (AD1) DRUG CLASS REVIEW

A. AD1 UF Relative Clinical Effectiveness: The Committee evaluated the relative clinical effectiveness of antidepressant medications. The drug class reviewed included all U.S. marketed antidepressants, except monoamine oxidase inhibitors (MAOIs) and tricyclic antidepressants (TCAs), which will be reviewed separately. Individual medications are outlined in the table below. Although the receptor-binding characteristics and pharmacological classification of these medications vary, the Committee agreed that there is sufficient overlap in their clinical use to review them as a single class of medications.

The Committee considered information concerning the safety, tolerability, efficacy, and clinical outcome of the AD1s. Like many medications, the AD1s have multiple potential uses in addition to the treatment of depression. The Committee's review focused most heavily on the use of these agents for depression, but also considered the clinical effectiveness of individual agents in the treatment of other psychiatric and non-psychiatric conditions. FDA-approved indications for the AD1s are outlined in the table below. The clinical review included, but was not limited to, the requirements stated in the UF Rule, 32 CFR 199.21.

Generic Name	**Brand Name**	**FDA-Approved Indications** (as of July 2005)
Selective Serotonin Reuptake Inhibitors (SSRIs)		
Citalopram	Celexa, generics	MDD
Escitalopram	Lexapro	MDD, GAD
Fluoxetine	Prozac, generics	MDD, OCD, PD, bulimia (pediatric labeling MDD, OCD)
Fluoxetine 90 mg caps (weekly regimen)	Prozac Weekly	MDD (maintenance of response only)
Fluoxetine (special packaging)	Sarafem	PMDD
Fluvoxamine	Generics	OCD (pediatric labeling)*
Paroxetine HCl	Paxil, generics	MDD, GAD, OCD, PD, PTSD, SAD
Paroxetine HCl controlled release	Paxil CR	MDD, PD, PMDD, SAD
Paroxetine mesylate	Pexeva	MDD, OCD, PD
Sertraline	Zoloft	MDD, OCD, PD, PTSD, PMDD, SAD (pediatric labeling OCD)
Serotonin – Norepinephrine Reuptake Inhibitors (SNRIs)		
Duloxetine	Cymbalta	MDD, DPNP
Venlafaxine	Effexor, generics	MDD
Venlafaxine extended release	Effexor XR	MDD, GAD, SAD
Serotonin-2 Antagonist/Reuptake Inhibitors (SARIs)		
Nefazodone	Generics	MDD
Trazodone	Desyrel, generics	MDD
Norepinephrine and Dopamine Reuptake Inhibitors (NDRIs)		
Bupropion	Wellbutrin, generics	MDD
Bupropion sustained release	Wellbutrin SR, generics	MDD
Bupropion extended release	Wellbutrin XL	MDD
Alpha-2 Receptor Antagonists		
Mirtazapine	Remeron, generics	MDD

MDD = Major Depressive Disorder, GAD = Generalized Anxiety Disorder, OCD = Obsessive Compulsive Disorder, PD = Panic Disorder, PTSD = Posttraumatic Stress Disorder, PMDD = Premenstrual Dysphoric Disorder; SAD = Social Anxiety Disorder; DPNP = Diabetic Peripheral Neuropathic Pain

*Fluvoxamine is approved for depression in other countries, including Canada.

1) *Safety and Tolerability:* The Committee assessed the comparative safety and tolerability of the AD1s, including common adverse effects, rare but serious adverse effects, potential for drug interactions, safety of use in special populations, the risk of adverse effects when discontinuing use (discontinuation syndrome), and safety/tolerability issues with special formulations of paroxetine, fluoxetine, and bupropion.

   a. Common Adverse Effects

      i. Adverse effect profiles of the AD1s are known to differ. A particular agent made be chosen to either avoid a known side effect, or to take advantage of a known side effect clinically (e.g., selecting an antidepressant likely to cause sedation for an elderly patient who is having difficulty sleeping).

      ii. Differences in clinical trials designs, patient populations, and methods of collecting adverse effect information make direct comparison of adverse effects difficult. Head-to-head trials comparing two or more AD1s are typically not powered to find significant differences in discontinuation rates due to adverse effects. Discontinuation rates in clinical trials are typically lower than in actual practice. In addition, many adverse effects tend to resolve with continued treatment and may or may not affect adherence to therapy or clinical outcomes. There are few long-term, prospective head-to-head trials under "real-world" conditions.

      iii. Overall, bupropion, fluoxetine, and paroxetine appear to be most associated with agitation/activation, while nefazodone, trazodone, and mirtazapine appear most likely to cause sedation. Anticholinergic effects have been reported with paroxetine and fluvoxamine. Gastrointestinal symptoms (e.g., nausea) are commonly reported with SSRIs, may be more common with venlafaxine, and may be less common with nefazodone, trazodone, bupropion, or mirtazapine. Diarrhea may occur more commonly with sertraline, compared to bupropion sustained release (SR), paroxetine, and mirtazapine.

      iv. Sexual dysfunction appears less likely to occur with bupropion, mirtazapine, trazodone, or nefazodone than with the SSRIs or SNRIs. There have been multiple trials supporting a lower risk of sexual dysfunction with bupropion compared to SSRIs.

      v. Elevations in blood pressure have been reported with the SNRIs (venlafaxine and duloxetine). This may be more frequent with venlafaxine than with duloxetine, although comparative data are lacking. There have also been reports of increases in blood pressure with bupropion and fluoxetine. Clinically relevant and statistically significant increases in cholesterol have been reported in a small percentage of patients treated with venlafaxine.

      vi. Most serotonergic antidepressants are associated with adverse effects when abruptly discontinued. This discontinuation syndrome appears to be related to elimination half-life, with symptoms occurring more frequently with medications with shorter half-lives (Propensity for syndrome among SSRIs)). fluvoxamine > paroxetine > sertraline > escitalopram > citalopram > fluoxetine (half-life 6 days). Venlafaxine, which has a short half-life, may be associated with more discontinuation symptoms than the SSRIs. Comparative information with duloxetine is unavailable, but discontinuation symptoms have been reported. Little information is available concerning discontinuation symptoms with trazodone; there have been only anecdotal

reports with nefazodone and mirtazapine. Discontinuation symptoms from abrupt discontinuation of bupropion, which has little effect on the serotonergic system, appear uncommon.

b. Rare but Serious Adverse Effects/Use in Special Populations

i. Abnormal bleeding, movement disorders, and hyponatremia have been reported rarely with SSRIs; there are insufficient data to determine if any one SSRI is associated with a higher risk.

ii. The manufacturer of duloxetine issued a "Dear Doctor" letter in Oct 2005 expanding existing recommendations to avoid use of duloxetine in patients with substantial alcohol use to include patients with pre-existing liver disease, following reports of hepatic injury in patients receiving duloxetine. Duloxetine is not recommended in patients with any degree of hepatic insufficiency due to substantially reduced clearance. Duloxetine is contraindicated in patients with uncontrolled narrow-angle glaucoma because it can cause mydriasis, and should be used in caution in patients receiving medications or having medical conditions that slow gastric emptying.

iii. Bupropion is contraindicated in patients with seizure disorder or conditions predisposing to seizure disorder or at increased seizure risk due to abrupt discontinuation of alcohol or sedatives. The risk of seizure in patients without predisposing factors appears low (0.1-0.4% at doses of 300-450 mg/d), but increases sharply at higher doses. Bupropion should be used with caution in hepatic impairment and extreme caution in severe hepatic cirrhosis.

iv. Nefazodone has a black box warning stating that it should not be used in patients with active liver disease or pre-existing transaminase elevation.

v. Trazodone should be used with caution in patients with cardiac disease. Priapism has been rarely reported with trazodone.

vi. Agranulocytosis has been rarely reported with mirtazapine.

vii. All AD1s are Pregnancy Category C except bupropion, which is Pregnancy Category B. Non-teratogenic adverse effects (e.g., respiratory distress) have been reported with serotonergic antidepressants when given in the third trimester. A recent epidemiological study cited in new labeling for paroxetine reported a greater than two fold increase in risk for birth defects in the first trimester with paroxetine compared to other SSRIs.

viii. A recent FDA analysis showed a higher risk of suicidal ideation or suicidality during the first few months of treatment with antidepressants in children and adolescents (4% vs. 2% with placebo). The FDA has issued a Public Health Advisory urging particular caution in watching for signs of worsening depression or suicidal thoughts at the beginning of antidepressant therapy or whenever the dose is changed, and this information has been added to antidepressant labeling in general. Despite a number of meta-analyses and observational studies addressing the risk of suicidality with antidepressants, no one antidepressant appears to be consistently associated with a higher risk of suicidality. The FDA continues to analyze data; adult results are expected in 2006.

c. Potential for drug interactions

i. Unlike fluoxetine, paroxetine, and fluvoxamine, which are metabolized by the cytochrome P450 system [fluoxetine and paroxetine inhibit P450 2D6 and fluvoxamine inhibits multiple P450 isoenzymes], sertraline, citalopram, and escitalopram are considered the least likely to result in significant drug interactions.

ii. Of the SNRIs, venlafaxine is primarily eliminated renally and has minimal effect on P450 isoenzymes; clinically meaningful drug interactions appear unlikely. Duloxetine has a moderate inhibitory effect on P450 2D6, is metabolized by 2D6 and 1A2, and may have increased hepatotoxicity in patients with substantial alcohol use. In addition it has a potential interaction with drugs affecting gastric acidity.

iii. Nefazodone, which inhibits 3A4, may interact with multiple medications. Information with trazodone is unclear. Bupropion does not appear to have substantial drug interactions, although it should not be used with drugs that lower the seizure threshold. Mirtazapine appears unlikely to cause substantial drug interactions, since it is metabolized by multiple pathways and does not appear to be a potent inhibitor of 2D6, 1A2, or 3A4.

d. Special Formulations

i. *Paroxetine controlled release (CR)* - The CR formulation of paroxetine (Paxil CR) is designed to release its contents over 4-5 hours after the medication reaches the small intestine; the intent is to reduce the incidence of nausea and related GI symptoms compared to the immediate release (IR) product. Both products are given once daily.

Based on pooled data from two 12-week, double-blind, randomized, placebo-controlled MDD trials comparing paroxetine CR and IR at similar doses [Golden et al. *J Clin Psychiatry* 2002; 63:577-84], patients receiving paroxetine CR showed significantly lower rates of nausea in the first week compared to paroxetine IR (14% vs. 23%, $p \leq 0.05$). Nausea rates began to decline in both groups starting in week 2, with no significant differences after week 1, and no numerical advantage for the CR formulation after week 3. Discontinuations due to adverse effects occurred in 6% of patients in the placebo group, 10% of patients in the paroxetine CR group ($p=0.14$ vs. placebo), and 16% of patients in the paroxetine IR group ($p=0.0008$ vs. placebo). There was no statistically significant difference between the CR and IR group. Discontinuations due specifically to nausea occurred in 3% of patients in the CR group, 4% in the IR group, and 0.5% in the placebo group.

There are no head-to-head trials comparing paroxetine CR to other SSRIs, and thus no direct evidence comparing rates of nausea or discontinuation due to adverse effects.

ii. *Fluoxetine 90-mg delayed release capsules (Prozac Weekly)* – Fluoxetine has a much longer half-life than other SSRIs, a fact that is exploited by the 90-mg weekly formulation. Fluoxetine weekly has an enteric coating that delays the onset of absorption by 1 to 2 hours relative to IR formulations, but does not otherwise extend the release of fluoxetine. It is FDA-approved only for maintenance of response in patients with MDD, not for initial therapy. The advantage of fluoxetine weekly is patient convenience and potentially increased adherence to treatment. This point has not been well-established, although one study reported greater compliance with the once-weekly regimen compared to 20 mg daily during a 3-month continuation phase [Claxton et al. *J Clin Psychiatry* 2000; 61:928-32]. Since compliance during a clinical

trial may be very different from compliance in practice, it is unclear whether this represents a real advantage for fluoxetine weekly. It is not clear whether fluoxetine 90 mg weekly is equivalent to fluoxetine 20 mg/d in maintaining response.

iii. *Fluoxetine in special packaging for premenstrual dysphoric disorder (PMDD) (Sarafem)* – Fluoxetine 10 and 20 mg capsules are available in special packaging and with special labeling for the treatment of PMDD, under the name of Sarafem. Usual dosing is 20 mg/day; the product does not appear to differ from the other branded fluoxetine product (Prozac), except for differences in the color of the capsules. When Sarafem was first introduced, the manufacturer stated the intent was to allow patients with PMDD to avoid the stigma associated with use of antidepressants.

iv. *Bupropion extended release (Wellbutrin XL)* – The main advantage offered by the extended release bupropion product (Wellbutrin XL) compared to sustained release bupropion is once-daily vs. twice-daily administration. This is not regarded as an overwhelming advantage for medications in most disease states, although there is some evidence that patients have poorer adherence to twice daily versus once daily regimens and that patients with depression have worse adherence to medication than non-depressed patients. In the case of bupropion sustained release, package labeling advises separating doses by 8 hours. Since patients are usually advised not to take bupropion late in the day due to its activating properties, bupropion sustained release is likely to be dosed in the morning and early afternoon, which may present more logistical problems than typical twice-daily regimens. Bupropion extended release may be taken as a single dose in the morning.

Safety /Tolerability Conclusion: The Committee concluded that adverse effect profiles differ across AD1s, but there are little data to support any substantial difference among AD1s with respect to tolerability. One possible exception is the SNRI venlafaxine, which appears to be associated with more adverse effects than the SSRIs. It is not clear whether duloxetine will prove to be better tolerated than venlafaxine. Bupropion, mirtazapine, nefazodone, and trazodone appear to have a lower risk of sexual dysfunction compared with SSRIs and SNRIs. The Committee agreed that fluvoxamine, fluoxetine, paroxetine, and duloxetine have a generally higher potential for drug interactions than citalopram, escitalopram, sertraline, and venlafaxine. Available evidence addressing the likelihood of discontinuation syndrome with SSRIs tends to correlate with a rank-order of risk based on half-life (greatest to least risk). fluvoxamine > paroxetine > sertraline > escitalopram > citalopram > fluoxetine. Venlafaxine has a short half-life, and may be associated with more discontinuation symptoms than SSRIs; duloxetine may be similar based on half-life. Discontinuation symptoms appear uncommon with bupropion; data are limited with trazodone, nefazodone, and mirtazapine. Rare but serious adverse effects appear to be associated with duloxetine (recent case reports of hepatotoxicity), bupropion (seizure), nefazodone (hepatotoxicity), mirtazapine (agranulocytosis), and trazodone (priapism). Drugs with issues of particular concern in specific patient populations include duloxetine (avoid in hepatic insufficiency, substantial alcohol use, liver disease, narrow angle glaucoma), paroxetine (recent epidemiological evidence of increased risk in pregnancy), and bupropion (avoid in patients with increased seizure risk).

2) Efficacy/Clinical Outcomes

a. Major Depressive Disorder (MDD)

i. *SSRIs vs. SSRIs* – Of 23 head-to-head trials comparing SSRIs to other SSRIs, very few reported any significant differences between SSRIs. These trials were mostly of short

duration, with many lasting only 6-8 weeks. They typically assessed changes on the two most commonly used depression scales, the Hamilton Rating Scale for Depression (HAM-D) and the Montgomery Asberg Depression Rating Scale (MADRS). Most of these trials reported response rates (≥ 50% decrease on the HAM-D or MADRS), with a few reporting remission rates (percent of patients achieving a certain HAM-D or MADRS score). A 9-month "real-world" effectiveness trial comparing paroxetine, sertraline, and fluoxetine in primary care patients with depression as determined by the primary care provider [Kroenke et al. *JAMA* 2001; 286:2947-55] found no significant differences in efficacy among these three SSRIs. Two meta-analyses of response rates performed by Oregon reviewers showed no differences between paroxetine and fluoxetine, and a very slight and probably clinically insignificant difference (RR 1.10, 95% CI 1.01-1.22) favoring sertraline over fluoxetine. Only two trials reported statistically significant differences in efficacy [Lepola et al. *Int Clin Psychopharmacol* 2003; 18(4):211-7; Moore et al. *Int Clin Psychopharmacol* 2005; 20(3):131-7]. Both of these trials reported greater efficacy with escitalopram compared to citalopram. A third trial comparing citalopram and escitalopram showed no significant differences [Burke et al. *J Clin Psychiatry* 2002; 53:331-6]. Results of an unpublished trial comparing escitalopram to sertraline supplied by the manufacturer of escitalopram showed no significant differences between these two SSRIs. There is no published data supporting greater efficacy for paroxetine CR or fluoxetine weekly, compared to the original formulations or to other SSRIs.

ii. *Venlafaxine vs. SSRIs* – There are a number of head-to-head trials and meta-analyses comparing venlafaxine and various SSRIs, including paroxetine, fluoxetine, sertraline, and escitalopram. Overall, few of these trials reported significant differences between SSRIs and venlafaxine. Two meta-analyses comparing venlafaxine to fluoxetine showed a modest efficacy advantage for venlafaxine [Smith et al. *Br J Psychiatry* 2002; 180:364-404; Oregon reviewers], although venlafaxine was associated with more adverse effects. Two 8-week, randomized, controlled trials comparing venlafaxine extended release (venlafaxine XR) to escitalopram showed no differences in efficacy [Montgomery et al. *Neuropsychobiol* 2004; 50(1):57-64; Bielski et al. *J Clin Psychiatry* 2004; 65(9):1190-6].

iii. *Duloxetine vs. SSRIs* – There are no published head-to-head trials designed to compare duloxetine with other AD1s, although limited comparative data are available from six 8-week duloxetine trials that included active control arms (fluoxetine or paroxetine). However, these trials were not powered to directly compare active treatments; fluoxetine or paroxetine doses were limited to 20 mg/d while duloxetine was dosed from 40 to 120 mg/d. Duloxetine 60 mg/d appeared generally comparable to escitalopram 10 mg/d based on results of an unpublished, randomized, placebo-controlled trial supplied by the manufacturer of duloxetine.

Based on *in vitro* data, duloxetine appears to bind more equally to serotonin and norepinephrine reuptake transporters than venlafaxine. This "more balanced" inhibition is theorized to have favorable effects on pain, since inhibitory modulation of pain signals in neural pathways occurs via release of both serotonin and norepinephrine. A complementary argument is that duloxetine may be a better treatment than other antidepressants for depressed patients presenting with "painful symptoms of depression." Support for this argument is limited. Patients with depression commonly present with physical (somatic) symptoms, including pain,

which resolve along with mood symptoms following anti-depressant treatment. Brannan et al. [*J Psychiatric Res* 2005; 39:43-53] reported results of a randomized, placebo-controlled trial assessing the effects of duloxetine on pain in depressed patients with painful symptoms at baseline. The mean difference in Brief Pain Index (BPI) average pain scores (0=no pain; 10 = as bad as you can imagine) was consistently a little less than a point lower with duloxetine vs. placebo, starting at week 1. The difference reached statistical significance at weeks 1, 2, and 5, but was not significantly different at endpoint (p=0.066). Whether these results translate into a real advantage for duloxetine compared to other antidepressants in depressed patients presenting with somatic symptoms of pain is unclear.

iv. *Venlafaxine vs. duloxetine* – There are no published head-to-head trials comparing venlafaxine and duloxetine for the treatment of depression. A 2005 meta-analysis [Vis et al. *Ann Pharmacother* 2005; 39:1789-807] comparing placebo-controlled trials with venlafaxine and duloxetine did not show a statistically significant difference between duloxetine and venlafaxine XR, although remission and response rates tended to favor venlafaxine XR. A summary of pooled results of two unpublished, double-blind, MDD randomized, controlled trials comparing duloxetine and venlafaxine supplied by the manufacturer of duloxetine showed no significant differences between venlafaxine and duloxetine based on Global Benefit-Risk assessment (a statistical method that weighs both efficacy and adverse effects), remission rate, or change from baseline in HAM-D total score.

v. *Bupropion* – Based on six head-to-head trials and one meta-analysis, bupropion appears similar in efficacy to SSRIs (fluoxetine, paroxetine, sertraline). There are no published data supporting greater efficacy for bupropion extended release, compared to the immediate or sustained release formulations of bupropion or to other SSRIs.

vi. *Mirtazapine* – Based on five head-to-head trials, mirtazapine appears similar in efficacy to SSRIs (fluoxetine, paroxetine, sertraline).

vii. *Nefazodone* – Based on three head-to-head trials, nefazodone appeared similar in efficacy to SSRIs (fluoxetine, paroxetine, and sertraline). One of these studies included pooled data from three trials with identical protocols focusing primarily on effects of nefazodone or fluoxetine on sleep quality; nefazodone appeared to significantly improve sleep quality compared to fluoxetine.

viii. *Trazodone* – Based on five 6-week trials, trazodone appeared similar in efficacy to fluoxetine and bupropion, and possibly less efficacious than venlafaxine, although insufficient evidence exists to draw any real conclusion. At present, the major role of trazodone in depressed patients appears to be as an adjunctive medication for the treatment of insomnia.

ix. *Treatment of depression in children and adolescents* – Fluoxetine is the only antidepressant FDA-approved for MDD in children and is used in most pediatric MDD trials. The FDA has concluded that only fluoxetine has been shown to have a favorable risk-benefit profile in pediatric patients, based on the fact that it is the only antidepressant that has demonstrated efficacy in a pediatric population.

b. *Other Psychiatric Conditions*:

i. *Generalized Anxiety Disorder (GAD)*. Venlafaxine, paroxetine, and escitalopram are FDA-approved for treatment of GAD. Sertraline appears to be efficacious for the

treatment of GAD based on results of a large published, placebo-controlled trial [Allgulander et al. *Am J Psychiatry* 2004; 161:1642-9]. Two head-to-head trials, one comparing paroxetine and sertraline and the other comparing paroxetine and escitalopram, reported no difference between active treatments based on reductions in anxiety (HAM-A) scores [Ball et al. *J Clin Psychiatry* 2005; 66:94-9; Bielski et al. *Ann Clin Psychiatry* 2005; 17:65-9].

ii. *Obsessive Compulsive Disorder (OCD).* Fluoxetine, fluvoxamine, paroxetine, and sertraline are FDA-approved for the treatment of OCD; fluoxetine, sertraline, and fluvoxamine are approved for use in children and adolescents. At least four separately conducted meta-analyses, one focusing on trials in pediatric patients, showed no significant difference between included SSRIs (fluoxetine, fluvoxamine, paroxetine, and sertraline). Two head-to-head trials, one comparing sertraline and fluoxetine, and the other comparing paroxetine and venlafaxine XR, showed no difference in efficacy between active treatments [Bergeron et al. *J Clin Psychopharmacol* 2002; 22(2):148-54; Denys et al. *J Clin Psychopharmacol* 2003; 23(6):568-75]. Citalopram appears to be effective for the treatment of OCD based on results of a long-term (> 6 month) trial [Montgomery et al. *Int Clin Psychopharmacol* 2001; 16:75-86].

iii. *Panic Disorder (PD).* Fluoxetine, paroxetine, and sertraline are FDA-approved for panic disorder. A head-to-head trial comparing sertraline and paroxetine showed no significant differences in efficacy [Bandelow et al. *J Clin Psychiatry* 2004; 65:405-13]. Fluvoxamine and venlafaxine XR appear efficacious based on short-term, placebo-controlled trials. Citalopram appears to be efficacious for panic disorder based on results of a placebo-controlled trial with a 1-year extension [Wade et al. *Br J Psychiatry* 1997; 170:549-53; Lepola et al. *J Clin Psychiatry* 1998; 59:528-34]. A 10-week trial comparing both citalopram and escitalopram to placebo reported significant improvement with both active treatments on many measures, including quality of life, although only escitalopram significantly reduced the frequency of panic attacks compared to placebo [Stahl et al. *J Clin Psychiatry* 2003; 64:1322-7]. This trial was not designed to compare active medications

iv. *Premenstrual Dysphoric Disorder (PMDD).* Fluoxetine (as Sarafem), paroxetine, and sertraline are FDA-approved for the treatment of PMDD. Evidence supporting efficacy is also available for citalopram, fluvoxamine, and venlafaxine [Wyatt et al. *Cochrane Database Syst Rev* 2002; 4:CD001396; Freeman et al. *Obstet Gynecol* 2001; 98(5 Pt 1):737-44]. There are no head-to-head trials.

v. *Post-Traumatic Stress Disorder (PTSD).* Sertraline and paroxetine are FDA-approved for PTSD. Mirtazapine may be efficacious in PTSD based on a 6-week, head-to-head, open-label trial with sertraline which showed a higher percentage of responders with mirtazapine [Chung et al. *Human Psychopharmacol* 2004; 19:489-94]. Published data supporting efficacy of fluoxetine for PTSD include two small, placebo-controlled trials, one of which showed a significant effect on prevention of relapse over a 6-month period [Connor et al. *Br J Psychiatry* 1999; 175:17-22; Davidson et al. *J Clin Psychopharmacol* 2005; 25:166-9].

vi. *Social Anxiety Disorder (SAD).* Paroxetine, sertraline, and venlafaxine are FDA-approved for the treatment of SAD. Two placebo-controlled trials comparing venlafaxine XR and paroxetine showed no differences in efficacy between active treatments, although venlafaxine XR appeared to be associated with a faster onset of

action in one trial [Liebowitz et al. *Arch Gen Psychiatry* 2005; 62:190-8; Allgulander et al. *Human Psychopharmacol* 2004; 19:387-96]. Escitalopram appears efficacious for SAD based on results of a placebo- and paroxetine-controlled trial [Lader et al. *Depress Anxiety* 2004; 19:234-40], and an additional 12-week, placebo-controlled trial [Kaspar et al. *Br J Psychiatry* 2005; 186:222-6]. A small trial with fluvoxamine showed significant improvement in efficacy compared to placebo [Stein et al. *Am J Psychiatry* 1999; 156:756-60].

vii. *Bulimia*. Fluoxetine is the only AD1 that is FDA-approved for treatment of bulimia. The majority of data (and all the larger trials) supporting efficacy of SSRIs for bulimia/binge eating disorder were done with fluoxetine. Although there are small trials with other AD1s, data are insufficient to draw conclusions about the efficacy of other AD1s for bulimia.

c. *Non-psychiatric conditions*

i. Diabetic peripheral neuropathic pain (DPNP)

A recent Cochrane systematic review [Saarto et al., *Cochrane Database System Rev*. 2005; (3):CD005454] addressed the use of antidepressants for the treatment of neuropathic pain in adult patients. The review included 50 trials of 29 antidepressants (total n=2515). The overall conclusion supported efficacy of TCAs for neuropathic pain, with amitriptyline having a number-needed-to-treat of 2 (95% CI 1.7-2.5) and a relative risk of 4.1 (95% CI 2.9-5.9) for obtaining at least moderate relief of pain. Researchers found limited evidence for the efficacy of SSRIs, and insufficient evidence for other antidepressants, including venlafaxine.

In addition to antidepressants, a number of anticonvulsants are used to treat DPNP. After excluding non-diabetic etiologies and stabilizing glycemic control, the American Diabetes Association advises starting treatment of DPNP with a TCA, (e.g., amitriptyline 25-150 mg at bedtime), or an anticonvulsant (e.g., gabapentin 1800 mg daily) [Boulton et al. *Diabetes Care* 2005; 28:956].

Duloxetine is FDA-approved for the treatment of DPNP. Safety and efficacy of duloxetine for the treatment of DPNP were established in two 12-week randomized controlled studies (total n=1074), one of which is published [Goldstein et al. *Pain* 2005; 116(1-2):109-18.]. Based on the published trial, the percent of patients achieving a $\geq$ 50% reduction in 24h Average Pain Score was 49% for patients receiving duloxetine 60 mg/d and 52% with 120 mg/d, compared to 26% of patients receiving placebo. The 60 mg/d dose of duloxetine was better tolerated.

Venlafaxine also appears to be efficacious and safe in DPNP. Rowbotham et al. [*Pain* 2004; 110:697-706] evaluated low dose (75mg) and high dose venlafaxine (150-225 mg) versus placebo in patients with painful diabetic neuropathy. The multicenter, double blind, randomized, placebo-controlled study included 244 adult outpatients with stable type 1 or 2 diabetes. At week 6, the percentage of patients achieving a 50% reduction in Visual Analog Pain Intensity score from baseline was 27% for placebo, 32% for 75mg, and 50% for 150-225mg, $p<0.001$ v. placebo.

Overall, there is insufficient evidence to determine the relative effectiveness of TCAs, SNRIs, or anticonvulsants for the treatment of DPNP or non-diabetic neuropathic pain. The AD1s and the newly introduced anticonvulsant pregabalin are not yet

represented in clinical practice guidelines for DPNP and comparative evidence versus more established therapies is largely unavailable.

ii. Other Non-Psychiatric Conditions

The Committee did not attempt to review all non-psychiatric conditions in which one or more of the AD1s may have a beneficial effect. Some of these apply only to very limited populations (e.g., neurocardiogenic syncope/recurrent idiopathic dizziness), to predictably exploit side effects of the medications (e.g., treatment of premature ejaculation with SSRIs), or to be only an additional option among multiple possible options (e.g., migraine prophylaxis). The Committee noted the following:

- Duloxetine is approved for the treatment of stress urinary incontinence in Europe, under the name of Yentreve. The manufacturer of duloxetine has rescinded its new drug application for U.S. approval for stress urinary incontinence (SUI). It is unclear whether clinical evidence was felt to be insufficient, or whether the FDA is further investigating reports of suicide attempts and suicidal ideation occurring during clinical trials of duloxetine for SUI. The FDA's information sheet on duloxetine currently suggests that physicians consider the data on suicidality before prescribing duloxetine for SUI. Increases in suicidality have not been reported in trials of duloxetine for depression or DPNP.
- There are several clinical trials assessing use of AD1s for the treatment of hot flashes, of particular interest because of the scarcity of effective options for women unwilling or unable to take estrogens. Short-term trials with several AD1s, including venlafaxine, paroxetine, and fluoxetine, have shown efficacy; however, a 9-month, placebo-controlled trial with citalopram and fluoxetine failed to show a significant decrease in hot flashes with either medication, compared with placebo. There are insufficient data to support greater efficacy for any one AD1.
- Duloxetine was shown to be efficacious for the treatment of fibromyalgia in female patients with or without MDD in a 10-week, randomized, double-blind, placebo-controlled trial [Arnold et al., *Am J Med* 2002; 112:191-7], based on significantly greater improvement with duloxetine on the Fibromyalgia Impact Questionnaire (FIQ) total score (mean difference -5.5 points; score range 0-80, 0 = no impact). Response rates, based on patients achieving a $\geq$ 50% reduction in FIQ pain score (score range 0-10, 0 = no impact), were 28% for duloxetine vs. 17% for placebo (p=0.06).

Efficacy / Clinical Outcome Conclusion: The Committee concluded that the AD1s offer similar efficacy in treating MDD with the exception of data supporting slightly greater efficacy with venlafaxine compared to the SSRIs and with escitalopram compared to citalopram. Fluoxetine has a unique advantage for the treatment of MDD in children.

The Committee noted that efficacy in other psychiatric conditions (GAD, OCD, PD, PMDD, PTSD, SAD, and bulimia) contributes to the overall usefulness of the AD1s. The Committee agreed that the existence of published clinical evidence supporting efficacy in these disease states should be taken into account in addition to FDA-approved indications. By this measure, paroxetine and sertraline appear to be the most broadly useful SSRIs. Bupropion, mirtazapine, trazodone, and nefazodone are indicated only for MDD. With regard to the SNRIs, venlafaxine has FDA-approved indications for GAD and SAD, in addition to MDD.

Duloxetine is the only AD1 with an FDA-approved indication for a non-psychiatric condition, DPNP. It is not clear whether duloxetine offers advantages over other agents used for the treatment of DPNP.

3) Provider Opinion

The Committee reviewed results of a survey sent to the Army, Navy, and Air Force specialty consultants, and distributed by them to MTF internal medicine, family practice, and psychiatry providers. The survey was also posted on the PEC's webforum, RxNet, to facilitate discussion. Providers were asked to identify clinical situations and differences in safety and tolerability among agents that would lead them to favor one antidepressant over another, and which antidepressants they rarely prescribed and could theoretically live without.

Of 42 responses, 21 were from psychiatrists and 21 from primary care practitioners including internal medicine and family practice. Overall, providers agreed that SSRIs as a class were more useful than SNRIs, followed by bupropion, trazodone, and mirtazapine.

Providers found sertraline to be most useful, followed by escitalopram, fluoxetine, citalopram, paroxetine, and fluvoxamine. About half of the responders perceived escitalopram to offer an efficacy or tolerability advantage over citalopram; the other half saw little or no difference. Provider comments indicated definite niches in therapy for sertraline (many indications; lower risk of adverse effects and drug interactions); fluoxetine (can be used in children, activating); venlafaxine (may be more effective than SSRIs but also has more adverse effects); bupropion (low risk of sexual adverse effects, can be used to treat sexual adverse effects from SSRIs; may be useful in smokers and ADHD patients); trazodone (treatment of sleep symptoms); and mirtazapine (sedating; may be useful to stimulate weight gain in elderly or oncology patients or in HIV wasting).

4) Overall Clinical Effectiveness Conclusion

- The Committee concluded that the AD1s offer similar efficacy in treating MDD with the exception of data supporting slightly greater efficacy with venlafaxine compared to the SSRIs and with escitalopram compared to citalopram. Fluoxetine has a unique advantage for the treatment of MDD in children. With respect to other psychiatric conditions, paroxetine and sertraline appear to be the most broadly useful AD1s based on FDA-approved indications and published clinical evidence. Duloxetine is the only AD1 with an FDA-approved indication for a non-psychiatric condition, DPNP; it is not clear whether duloxetine offers advantages over other agents used for the treatment of DPNP.
- The Committee concluded that adverse effects differ across AD1s, but there are little data to support any substantial difference among AD1s with respect to tolerability. One possible exception is the SNRI venlafaxine, which appears to be associated with more adverse effects than the SSRIs. It is not clear whether duloxetine will prove to be better tolerated than venlafaxine. The difference in adverse effects between agents may affect the choice of agent in individual patients, creates specific niches in which adverse effects become useful therapeutic effects (e.g., mirtazapine), and increases the number of AD1s necessary to provide adequate clinical coverage.
- Bupropion, mirtazapine, nefazodone, and trazodone appear to have a lower risk of sexual dysfunction compared with SSRIs and SNRIs. Fluvoxamine, fluoxetine, paroxetine, and duloxetine have a generally higher potential for drug interactions than

citalopram, escitalopram, sertraline, and venlafaxine. The likelihood of discontinuation syndrome with the SSRIs appears to correlate with half-life. Venlafaxine may be associated with more discontinuation symptoms than SSRIs; duloxetine may be similar, although data are lacking. Discontinuation symptoms appear to be rare with bupropion, which has little serotonergic effect.

- Rare but serious adverse effects include recent case reports of hepatotoxicity with duloxetine, increased seizure risk with bupropion, hepatotoxicity with nefazodone, agranulocytosis with mirtazapine, and priapism with trazodone. Drugs with issues of particular concern in specific patient populations include duloxetine (avoid in hepatic insufficiency, substantial alcohol use, liver disease, narrow angle glaucoma), paroxetine (recent epidemiological evidence of increased risk in pregnancy), and bupropion (avoid in patients with increased seizure risk). All AD1s are Pregnancy Category C except for bupropion, which is Pregnancy Category B.

COMMITTEE ACTION: The Committee voted (17 for, 0 opposed, 1 abstained, 1 absent) to accept the clinical effectiveness conclusion as stated above.

B. AD1 UF Relative Cost Effectiveness. The P&T Committee evaluated the relative cost effectiveness of the AD1s in relation to safety, tolerability, effectiveness, and clinical outcomes of the other agents in the class. Information considered by the P&T Committee included but was not limited to sources of information listed in 32 C.F.R. 199.21(e) (2).

To determine the relative cost effectiveness of the AD1s, two separate economic analyses were performed a pharmacoeconomic analysis and BIA. From the preceding relative clinical effectiveness evaluation, the P&T Committee determined that AD1s differed in regards to efficacy, safety, and tolerability in the treatment of MDD and other psychiatric illness. To account for the difference in relative clinical effectiveness in this therapeutic class, two cost effectiveness analyses (CEAs) were performed a CEA based on the results obtained via a multi-attribute utility theory (MAUT) analysis, and a CEA based on the findings reported in *Drug Class Review on Second Generation Antidepressants* by the Oregon Health & Science University Drug Effectiveness Review Project (OHSU-DERP). In a CEA, the agents within a therapeutic class are competed on two dimensions, cost and effect (outcomes). In both CEAs, the drug cost used in the analysis was the point of service adjusted total weighted average cost per day of treatment (for all three points of service).

The CEA-MAUT was presented first. For this analysis, the effectiveness measure used for each agent was the composite score derived from the MAUT analysis that ranked the agents based on clinical outcome evidence. The MAUT accounted for the differences in clinical outcome evidence; FDA indication supporting an agent's use for psychiatric and non-psychiatric conditions other than MDD, such as GAD, PTSD, DPNP, etc.; evidence supporting efficacy and safety in the pediatric population; differences in safety (e.g., drug interactions, use in pregnancy, contraindications, potential for cardiovascular adverse events, and potential for rare but serious adverse events); and differences in tolerability (e.g., sexual dysfunction).

Overall, the results of the CEA-MAUT were as follows:

- Trazodone was determined to be the most cost-effective agent;
- Fluoxetine and sertraline were determined to be more cost effective and more costly compared to trazodone;

- Other agents were shown to be less effective and more costly, compared to trazodone, fluoxetine, and sertraline.

With respect to the SSRIs:

- Fluoxetine was most-effective, followed by citalopram, paroxetine IR, escitalopram, and paroxetine CR, in that order.

With respect to the SNRIs:

- Venlafaxine was shown to be more cost-effective compared to duloxetine.

With respect to the other AD1s:

- Trazodone was the most cost effective agent followed by mirtazapine, nefazodone, bupropion SR, and bupropion XL, in that order.
- (Note: Although trazodone was determined to be the most cost-effective agent, and nefazodone was shown to be more cost-effective compared to bupropion SR and bupropion XL, neither trazodone nor nefazodone was considered a viable first-line monotherapy treatment alternative for MDD).

The second cost effectiveness analysis (CEA-Response) was based on the OHSU-DERP report for MDD. This report examined 49 head-to-head randomized controlled clinical trials and one systematic review. The overall conclusion of the report was that "effectiveness and efficacy were similar and the majority of trials did not identify substantial differences among drugs. Studies were often small and relatively underpowered to detect significant differences in efficacy." However, both the OHSU-DERP report and the PEC clinical review did acknowledge that there was some evidence to suggest that escitalopram is more effective compared to citalopram; venlafaxine has a modest but statistically significant additional treatment effect compared to fluoxetine; and that escitalopram and venlafaxine are equally effective. However, one of two studies reported significantly greater discontinuations due to adverse effects in the venlafaxine group than in the escitalopram group. To account for these potential differences in clinical outcomes, a CEA-Response model was constructed. This model examined the costs and outcomes of treatment for MDD during the acute phase of treatment (8-weeks). In addition to drug costs, other direct medical costs included provider costs and costs associated with the treatment of adverse events. The effectiveness measure was reported response rate at 8-weeks.

Overall, the results from the CEA-Response analysis revealed that:

- Fluoxetine was the most cost-effective agent;
- Escitalopram was more effective and more costly;
- Venlafaxine was equivalent in effectiveness compared to escitalopram, but was significantly more costly;
- Other agents were equivalent in effectiveness compared to fluoxetine but were more costly.

A summary analysis was then conducted based on the CEA-MAUT and CEA-Response results. The summary analysis focused on comparisons either between the most cost-effective agent and

the more costly agents within a sub-class or between a generic agent and its branded product extension (e.g., paroxetine IR and paroxetine CR). This analysis focused on the:

- SSRIs – fluoxetine in special packaging for PMDD (Sarafem), fluoxetine weekly (Prozac Weekly), sertraline, escitalopram, and paroxetine CR;
- SNRIs – venlafaxine versus duloxetine;
- Bupropion XL versus Bupropion SR.

The results of the summary analysis showed:

For the SSRIs:

- Fluoxetine branded product extensions - Sarafem and Prozac Weekly were > 7-fold more costly and had similar relative clinical effectiveness compared to generic fluoxetine;
- Sertraline had equal (CEA-Response) or slightly greater (CEA-MAUT) relative clinical effectiveness but was significantly more costly compared to fluoxetine;
    - (Note. sertraline is projected to go generic in June 2006)
- Escitalopram was shown to have lower overall relative clinical effectiveness (CEA-MAUT) compared to fluoxetine but potentially greater relative clinical effectiveness in the treatment of MDD (CEA-Response) compared to citalopram, however at a significantly greater cost;
- The CEA-MAUT and CEA-Response both showed the paroxetine IR and paroxetine CR had similar relative clinical effectiveness, but paroxetine CR was significantly more costly compared to paroxetine IR.

For the SNRIs:

- Venlafaxine was shown to have greater overall relative clinical effectiveness (CEA-MAUT) and greater relative clinical effectiveness in the treatment of MDD (CEA-Response) compared to duloxetine for a similar cost;
- Bupropion XL was shown to have greater overall relative clinical effectiveness (CEA-MAUT) but similar relative clinical effectiveness in the treatment of MDD (CEA-Response) compared to bupropion SR at a significantly greater cost.

The results of the CEAs were subsequently incorporated into a BIA. A BIA accounts for other factors and costs associated with a potential decision to recommend that one or more agents be classified as non-formulary, such as: market share migration, cost reduction associated with non-formulary cost shares, and medical necessity processing fees. The goal of the BIA was to assist the Committee in determining which group of AD1s best meets the clinical needs of the DoD population at the lowest cost to the MHS. Based on the BIA results and other clinical considerations (e.g., the need to make a broad array of antidepressants available to meet the clinical coverage needs), the Committee agreed that a group of AD1s that included bupropion (IR, SR), citalopram, fluoxetine, fluvoxamine, mirtazapine, nefazodone, paroxetine IR, sertraline, trazodone, and venlafaxine best achieved this goal when compared to other combination groups of AD1s, and thus were determined to be more cost-effective relative to other combination groups.

Conclusion: The P&T Committee, based upon its collective professional judgment, voted (12 for, 5 opposed, 1 abstention, 1 absent) to accept the AD1 cost-analysis presented by the PEC. The P&T Committee concluded that: fluoxetine in special packaging for PMDD (Sarafem), fluoxetine weekly (Prozac Weekly), escitalopram, and paroxetine CR were not cost-effective relative to the other agents within the SSRI sub-class; duloxetine was not cost-effective compared to venlafaxine; bupropion XL was not cost-effective compared to bupropion. Ultimately, the P&T committee did not value escitalopram's potentially greater relative clinical effectiveness in the treatment of MDD (based on clinical trial evidence supporting a clinical efficacy advantage over citalopram) or bupropion XL's greater overall relative clinical effectiveness (based on its once-daily dosing regimen) enough to overcome the agents' significantly higher cost. Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of the AD1s, and other relevant factors, the P&T Committee recommended that fluoxetine in special packaging for PMDD (Sarafem), fluoxetine weekly (Prozac Weekly), escitalopram, and paroxetine CR, duloxetine, and bupropion XL be classified as non-formulary under the UF and that bupropion (IR, SR), citalopram, fluoxetine, fluvoxamine, mirtazapine, nefazodone, paroxetine (HCl and mesylate formulations), sertraline, trazodone, venlafaxine and venlafaxine extended release be classified as formulary on the UF. The P&T Committee recommended that existing quantity limits for fluoxetine 90-mg delayed release capsules (Prozac Weekly) of 4 capsules per 30 days, 12 capsules per 90 days be continued, since there is little new information to support the safety and efficacy of weekly doses exceeding 90 mg.

COMMITTEE ACTION. The P&T Committee, based upon its collective professional judgment, voted (17 for, 0 opposed, 1 abstention, 1 absent) to recommend that fluoxetine in special packaging for PMDD (Sarafem), fluoxetine weekly (Prozac Weekly) escitalopram, and paroxetine CR, duloxetine, and bupropion XL be classified as non-formulary under the UF, with bupropion (IR, SR), citalopram, fluoxetine, fluvoxamine, mirtazapine, nefazodone, paroxetine, sertraline, trazodone, venlafaxine and venlafaxine extended release remaining on the UF. In addition, the P&T Committee recommended that existing quantity limits for fluoxetine 90-mg delayed release capsules (Prozac Weekly) of 4 capsules per 30 days, 12 capsules per 90 days be continued.

C. AD1 UF Medical Necessity Criteria: Based on the clinical evaluation of the AD1s and the conditions for establishing medical necessity for a non-formulary medication provided for in the UF rule, the P&T Committee concluded that the following general medical necessity criteria would apply for these agents:

1.) Use of formulary agents is contraindicated, and the use of a non-formulary agent is not contraindicated.

2). The patient has experienced or is likely to experience significant adverse effects from the formulary agents, and the patient is reasonably expected to tolerate a non-formulary agent.

3) Use of the formulary agent resulted in therapeutic failure, and the patient is reasonably expected to respond to a non-formulary agent.

4) The patient has previously responded to a non-formulary agent and changing to a formulary agent would incur unacceptable risk.

5) There is no alternative pharmaceutical agent on the formulary.

With respect to criteria 2 and 3, the Committee noted the following:

Adverse effect profiles are known to differ among the AD1s and other factors may play a part in selecting an agent for a particular patient (e.g., symptoms of sedation or agitation, family history of efficacy). Clinical practice guidelines support SSRIs as the first choice in most patients, and support trying a second SSRI in patients who have failed a first SSRI due to lack of efficacy, but they do not support trying all available SSRIs before being treated with an antidepressant with a different mechanism of action.

- For escitalopram, the Committee supported medical necessity in the following cases:
  - The patient has previously failed adequate trials of at least two other SSRIs (at least 8 weeks each), without response or remission, and other formulary medications (such as venlafaxine and bupropion) are not appropriate for treatment.
  - The patient has previously tried at least two other SSRIs and could not tolerate the adverse effects, and other formulary medications (such as venlafaxine and bupropion) are not appropriate for treatment.
- For duloxetine, the Committee supported medical necessity in patients who have tried and failed, or were unable to tolerate, venlafaxine, and in whom other formulary medications (e.g., SSRIs and bupropion) are not appropriate for treatment.
- The Committee had difficulty envisioning circumstances in which paroxetine controlled release (Paxil CR), bupropion extended release (Wellbutrin XL), fluoxetine 90 mg extended release capsules (Prozac Weekly), and specially packaged fluoxetine for PMDD (Sarafem) would be considered medically necessary, since all of these medications would be available on the UF in other formulations. With respect to paroxetine CR, which has data supporting a significantly lower incidence of nausea in the first week after starting therapy compared to the IR formulation, the Committee agreed that one circumstance in which paroxetine CR could be considered medically necessary might be in a patient who had previously responded to paroxetine and who had other predisposing factors for nausea (e.g., chemotherapy or a GI disorder).

With respect to criterion 5, the Committee agreed that medical necessity criteria for duloxetine in DPNP should be based on national clinical practice guideline recommendations for treatment of DPNP. The Committee also agreed that duloxetine could be considered medically necessary in other types of neuropathic pain (e.g., phantom limb syndrome) under criterion #5 if reliable evidence exists for safety and efficacy and more accepted therapies are not clinically appropriate.

COMMITTEE ACTION: The Committee voted (16 for, 0 opposed, 1 abstained, 2 absent) to accept the AD1s medical necessity criteria.

D. AD1 UF Implementation Plan: Because a substantial number of patients is currently receiving non-formulary AD1s and the need to carefully assess and monitor patients taking this class of medication, the P&T Committee recommended an effective date no later than the first Wednesday following a 180-day implementation period. The implementation period will begin immediately following the approval by the Director, TMA.

COMMITTEE ACTION: The Committee voted (16 for, 0 opposed, 1 abstained, 2 absent) to recommend an implementation period of 180 days.

E. AD1 Basic Core Formulary (BCF) Review and Recommendations: The P&T Committee reviewed the AD1s recommended for inclusion on the UF to select recommended

agents for the BCF. Based on the outcome of relative clinical effectiveness determinations, the Committee decided that three or four SSRIs, zero or one SNRIs, and zero to two other agents (bupropion, mirtazapine, nefazodone, or trazodone) would be added to the BCF. AD1s currently on the BCF include: citalopram, fluoxetine (excluding Sarafem and Prozac Weekly), paroxetine (excluding Paxil CR), sertraline, venlafaxine extended release, bupropion sustained release (but not Wellbutrin XL), and trazodone.

With respect to the SSRIs, the Committee agreed that it was reasonable to add fluoxetine (excluding Prozac Weekly and Sarafem) and citalopram to the BCF, based on cost effectiveness and clinical effectiveness considerations. In addition, the Committee agreed that sertraline should be added to the BCF despite its significantly higher cost compared to fluoxetine and citalopram. Sertraline is the most commonly used SSRI in MTFs and its relative clinical effectiveness based on the CEA-MAUT was slightly greater than other SSRIs, primarily as a result of its FDA-approved indications and evidence supporting efficacy in a large number of psychiatric conditions in addition to MDD, as well as its relatively low risk of drug interactions and adverse effects. Sertraline is expected to become generically available in June of 2006. Given the inclusion of fluoxetine, citalopram, and sertraline, the Committee agreed that paroxetine IR should not be added to the BCF. Reasons for not adding paroxetine to the BCF include: 1) it's not as cost effective as fluoxetine and citalopram, 2) it has declining use in MTFs, 3) it was ranked lower by providers compared to other SSRIs, 4) it has a relatively high risk of drug interactions and adverse effects, 5) a high risk of discontinuation syndrome; and 6) a recent labeling change regarding use in pregnancy.

With respect to the SNRIs, the Committee concluded that venlafaxine should not be added to the BCF. Although venlafaxine may be slightly more efficacious than SSRIs, it is also associated with more adverse effects, including the potential for increases in blood pressure. It is typically not used for initial treatment. The cost of venlafaxine is at least two-fold higher than treatment with any SSRI and several times higher than treatment with the most cost-effective SSRI. While SNRIs have a definite place in therapy, the Committee agreed that it was not necessary to retain an SNRI on the BCF.

With respect to the other AD1s, the Committee agreed that trazodone and bupropion sustained release should be added to the BCF. Trazodone is relatively commonly used in MTFs (about 12,000 prescriptions per month), is available at low cost, and its use as an adjunctive medication for insomnia in depressed patients was supported by provider opinion. Bupropion sustained release is also commonly used in MTFs, and has a definite and well-supported role in treatment of patients who have experienced or are concerned about sexual dysfunction with SSRIs.

COMMITTEE ACTION: The P&T Committee voted (17 for, 0 opposed, 1 abstained, 1 absent) to recommend the following as the BCF agents: fluoxetine (excluding Prozac Weekly and Sarafem, which are non-formulary), citalopram, sertraline, trazodone, and bupropion SR**.**

12. MACROLIDES/KETOLIDE DRUG CLASS REVIEW

A. Macrolide/Ketolide Relative Clinical Effectiveness: The DoD P&T Committee evaluated the relative clinical effectiveness of the macrolides: azithromycin (Zithromax), azithromycin 2 gram extended release suspension (Zmax), clarithromycin IR (Biaxin and various generics), clarithromycin extended release (ER) (Biaxin XL), all erythromycin salts and esters as well as erythromycin/sulfisoxazole combination suspension (various generics); and the ketolide, telithromycin (Ketek). Information regarding the safety, effectiveness, and clinical outcomes

for the treatment of various infections was considered. The clinical review included, but was not limited to, the requirements stated in the UF Rule, 32 CFR 199.21.

1) Spectrum of Activity/Resistance: Increasing use of macrolides has resulted in increased rates of macrolide resistant *S. pneumoniae.* Macrolide resistance to *S. pneumoniae* appears to be a class effect. *In-vitro*, telithromycin remains active against macrolide and penicillin resistant *Streptococcus*, and is the only agent in the class with an FDA indication for multi-drug resistant *S. pneumoniae* (MDRSP). However, telithromycin's ability to overcome MDRSP has not resulted in higher cure rates. *H. influenzae* is commonly resistant to erythromycin, whereas azithromycin, clarithromycin and telithromycin are active against *H. influenzae*

2) Efficacy

a) Endpoints: Endpoints in the clinical trials included clinical cure rate, bacteriologic eradication, and antibiotic failure rates. Any applicable trials evaluating clinical outcomes, such as mortality, hospital admission rates, or length of hospitalization, were also evaluated.

b) Efficacy for Community Acquired Pneumonia (CAP)

Place in Therapy: The American Thoracic Society (ATS), the Infectious Diseases Society of America (IDSA), and the Canadian Infectious Diseases Society/Canadian Thoracic Society (CIDS/CTS) guidelines do not give a preference for azithromycin or clarithromycin for treating CAP, but state that erythromycin is not preferred due to poor tolerability and limited spectrum of activity. There are no specific recommendations yet for telithromycin, although an update in ATS/IDSA guidelines is expected soon.

Efficacy of Macrolides/Ketolide: The Committee reviewed 17 head-to-head trials comparing one macrolide/telithromycin to another macrolide/telithromycin, or one macrolide/telithromycin versus another antimicrobial agent. Sixteen trials showed similar cure rates and/or bacteriological eradication rates. One poor quality trial comparing azithromycin to clarithromycin found a significant decrease in length of hospitalization and mortality with azithromycin. Another trial examined healthcare utilization from two pooled trials comparing clarithromycin IR to telithromycin. Despite equivalent cure rates in the individual trials, telithromycin was associated with significantly fewer CAP-related hospitalizations than clarithromycin IR in the pooled analysis. The original studies in the pooled analysis were not designed to analyze healthcare utilization; therefore, results were interpreted with caution.

CAP Conclusion: The Committee concluded there was no evidence of a difference in clinical cure rates/bacterial eradication rates between azithromycin, Zmax, clarithromycin IR/ER, erythromycin, and telithromycin when treating CAP. Erythromycin may have limited clinical utility in treating CAP caused by *H. influenzae,* due to its inactivity against the microorganism.

c) Efficacy for Acute Bacterial Exacerbation of Chronic Bronchitis (ABECB):

Place in Therapy: Guidelines from the American College of Physicians (ACP), American Society of Internal Medicine (ASIM), and American College of Chest Physicians do not give specific recommendations for the treatment of ABECB. Other recommendations from noted infectious disease physicians state azithromycin and clarithromycin are recommended in patients with uncomplicated ABECB (< 65 years of age; < 4 exacerbation per year, no co-morbidities, and minimal or no impairment in pulmonary function). Erythromycin was not recommended due to limited activity

against *H. influenzae.* No guidelines or recommendations have addressed the use of telithromycin for ABECB.

Efficacy of Macrolides/Ketolide: The Committee reviewed six double-blind, head-to-head trials comparing one macrolide/telithromycin to another macrolide, or another antimicrobial agent. All six trials showed similar cure rates and/or bacteriological eradication rates for the treatment of ABECB. One trial evaluated healthcare utilization, and found telithromycin was associated with significantly fewer respiratory-related hospitalizations, all-cause hospitalizations, and emergency room visits than clarithromycin IR, despite similar clinical cure rates. Healthcare utilization was a secondary endpoint to this study, and results should be interpreted with caution.

ABECB Conclusions: The Committee concluded there is no evidence of a difference in clinical cure rates/bacterial eradication rates between azithromycin, Zmax, clarithromycin IR/ER, erythromycin, and telithromycin when treating ABECB. Erythromycin may have limited clinical utility in treating ABECB caused by *H. influenzae,* due to its inactivity against the microorganism

d) Efficacy for Acute Bacterial Sinusitis (ABS):

Place in Therapy: Treatment guidelines from the American Academy of Pediatrics (AAP) and the Sinus and Allergy Health Partnership (SAHP) recommend clarithromycin and azithromycin in patients with mild uncomplicated ABS who have a type I hypersensitivity to penicillin. The AAP guidelines no longer recommend erythromycin for ABS due to the increasing resistance. However, the SAHP guidelines do not give preference to any macrolide, and include telithromycin in the same treatment category as the other macrolides for ABS.

Efficacy of Macrolides/Ketolides: Six double-blind, head-to-head trials comparing a macrolide/telithromycin to another macrolide or another antimicrobial showed similar cure rates and/or bacteriological eradication rates for the treatment of ABS. A retrospective cohort study of 29,102 patients with ABS concluded that newer broad spectrum antibiotics (azithromycin clarithromycin and amoxicillin-clavulanate) were no better than amoxicillin, trimethoprim-sulfamethoxazole, or erythromycin.

ABS Conclusions: The Committee agreed that all the macrolides (azithromycin, Zmax, clarithromycin IR/ER, and erythromycin) and telithromycin have shown efficacy for the treatment of ABS, and there is no evidence of a difference in clinical cure rates/bacterial eradication rates between the products when treating ABS.

e) Efficacy for Acute Pharyngitis:

Place in Therapy: The IDSA guidelines and a position paper by the ACP/ASIM for the treatment of group A β-hemolytic streptococcus pharyngitis (GABHS) recommend erythromycin only in patients with a history of a penicillin allergy. Erythromycin is recommended due to its narrow spectrum of activity compared to azithromycin and clarithromycin. Azithromycin, clarithromycin, or telithromycin are recommended in patients who cannot tolerate erythromycin.

Efficacy of Macrolides/Ketolide: Three trials comparing clarithromycin IR to azithromycin or telithromycin, as well as one trial comparing azithromycin to erythromycin showed similar clinical cure rates. Six trials comparing all the products,

(except Zmax, which has not been studied) have shown similar cure rates to penicillin, the gold standard for the initial treatment of acute pharyngitis.

Acute Pharyngitis Conclusions: The Committee agreed that azithromycin, clarithromycin IR/ER, erythromycin, and telithromycin have shown efficacy for the treatment of pharyngitis, and there is no evidence of a difference in clinical cure rates/bacterial eradication rates between the products. Currently there are no published trials evaluating Zmax for the treatment of acute pharyngitis.

f) Efficacy for Acute Otitis Media (AOM):

Place in Therapy. *T*he AAP and the American Academy of Family Physicians (AAFP) guidelines recommended macrolides as third-line agents, with use reserved for patients with a history of a type I reaction to penicillins and cephalosporins. The guidelines state that azithromycin, clarithromycin, and erythromycin/sulfisoxazole are all considered preferred macrolides. Erythromycin alone is not recommended due to its lack or activity against *H. influenzae*.

Efficacy of Macrolides: Two head-to-head trials comparing azithromycin to clarithromycin showed similar clinical cure rates. In addition, trials comparing azithromycin, clarithromycin IR, erythromycin-sulfisoxazole and erythromycin to either standard dose amoxicillin or amoxicillin-clavulanate showed similar cure rates. There were no clinical trials found evaluating clarithromycin ER, Zmax, and telithromycin for the treatment of AOM, and these agents do not have an FDA indication for the treatment of AOM.

AOM Conclusions: The Committee agreed that azithromycin, clarithromycin IR, erythromycin-sulfisoxazole and erythromycin have shown efficacy against AOM versus amoxicillin or amoxicillin-clavulanate, and there is no evidence of a difference in clinical cure rates/bacterial eradication rates between the products. Erythromycin alone may not be as effective for AOM compared to the other macrolides due to its inactivity against *H. influenzae*. There were no clinical trials found evaluating clarithromycin ER, Zmax and telithromycin for the treatment of AOM.

g) Efficacy for H. pylori infections and Mycobacterium avium complex (MAC):

Macrolides/ketolides are also used to treat infections cause by mycobacterium avium complex in the immunocompromised population and *H. pylori*-associated peptic ulcer disease. These infections occur with less frequency in DoD than respiratory infections. Thus, the Committee briefly reviewed the data and concluded the following: 1) For *H. pylori* eradication, clarithromycin-based regimens appear to be superior to azithromycin-based regimens; and 2) other macrolide/ketolides have not been adequately evaluated. For the prevention of MAC, either azithromycin or clarithromycin IR is recommended; there is insufficient data from the other macrolides/ketolides to recommend their use. For treatment of MAC, clarithromycin IR may be superior to azithromycin at clearing MAC from the blood, but trials have shown no mortality difference between the two drugs.

3) Safety and Tolerability:

Rare but Serious Adverse Drug Reactions (ADRs): All the macrolides/ketolides have the propensity, based on case reports and clinical trials, to cause pseudomembranous colitis, hepatotoxicity, and to prolong the QTc interval. Erythromycin and telithromycin

may cause exacerbation of myasthenia gravis, and should be used with caution in these patients.

Other ADRs: All the macrolide/ketolide products can cause taste perversion/abnormal taste, dizziness, rash, headache, and transient hearing loss. Cases of visual disturbances have been reported with telithromycin.

GI ADRs: Erythromycin has the highest incidence of GI adverse effects (abdominal pain, diarrhea, nausea/vomiting) compared to the other products. Package insert data suggest that Zmax and telithromycin cause more GI related adverse effects than clarithromycin IR/ER or azithromycin.

Special Populations. Pregnancy and Pediatric: Azithromycin and erythromycin are rated pregnancy category B rating whereas clarithromycin and telithromycin are rated pregnancy category C. Azithromycin, clarithromycin IR, and erythromycin are the only agents that have been evaluated in pediatric patients.

Drug Interactions: Azithromycin and Zmax are not metabolized via hepatic cytochrome P450 3A4 mechanisms, and are associated with fewer drug interactions than clarithromycin IR/ER, erythromycin, or telithromycin.

Overall Safety and Tolerability Conclusion: The Committee concluded that azithromycin and Zmax have the most favorable safety/tolerability profile, followed by clarithromycin and telithromycin, with erythromycin having the least favorable safety/tolerability profile.

4) Other Factors:

Pharmacokinetics: Erythromycin stearate and base need to be given on an empty stomach, whereas erythromycin ethylsuccinate and estolate can be given without regard to meals. Zmax bioavailability increases greater than two-fold when administered with food, but should be given on an empty stomach due the possibility of increasing the risk of adverse effects. Azithromycin, clarithromycin and telithromycin can be given without regard to meals. Azithromycin and Zmax are not interchangeable, due to differences in absorption and the time to reach peak serum concentration. Both clarithromycin and telithromycin require dosage adjustment for renal dysfunction; telithromycin requires dosage adjustment for liver dysfunction with concomitant renal dysfunction.

Dosing: The following agents can be given daily. Azithromycin, clarithromycin ER, and telithromycin. Clarithromycin IR is dosed twice daily, whereas erythromycin can be dosed between two to four times daily. Zmax is the only agent that is administered as a one-time dose.

Palatability of Oral Suspensions: Clinical studies evaluating taste preferences of antibiotic suspensions showed that pediatric patients preferred the taste of azithromycin over clarithromycin or erythromycin/sulfisoxazole.

Provider Opinion: A survey of DoD providers revealed that MDRSP was not considered a problem when treating CAP in the outpatient setting; there was not an advantage of Zmax's one time dosing versus other azithromycin products; azithromycin was preferred over the other agents in the class; and telithromycin and Zmax were thought to confer no additional benefit over the other members in the drug class.

Conclusions for Other Factors: There are minor differences in the pharmacokinetic profiles, dosing frequency, and palatability of the macrolides/ketolides that can affect individual patient preferences.

Overall Clinical Effectiveness Conclusion: The Committee concluded: (1) telithromycin *in vitro* shows activity against MDRSP, but this has not translated into superior clinical cure/improvement/bacteriological eradication rates in clinical trials; (2) erythromycin may have a limited role in treating many common types of upper and lower respiratory tract infections due to inactivity against *H. influenzae*; (3) clinical cure rates/bacterial eradication rates are similar between the macrolides/ketolides when used for treating CAP, ABECB, ABS, and acute pharyngitis; (4) for AOM, there is no clinical trial experience with clarithromycin ER or Zmax; clinical cure rates are similar with the other products; (5) clarithromycin IR has the best evidence for the treatment of *H. pylori* infections; (6) either azithromycin or clarithromycin can be used for prevention of MAC infection and clarithromycin IR is preferred over azithromycin for the treatment of MAC infections; (7) azithromycin is preferred relative to other macrolides and telithromycin in terms of safety and tolerability; and (8) there are minor differences amongst the agents in terms of other factors. Overall, the Committee concluded that azithromycin has increased overall clinical effectiveness relative to Zmax, clarithromycin IR/ER, erythromycin, and telithromycin.

COMMITTEE ACTION: The DoD P&T Committee voted (17 for, 0 opposed, 1 abstained, 1 absent) to accept the clinical effectiveness conclusion as stated above.

B. **Macrolide Antibiotic UF Relative Cost Effectiveness:** In considering the relative cost effectiveness of pharmaceutical agents in this class, the P&T Committee evaluated the costs of the agents in relation to the safety, effectiveness, and clinical outcomes of the other agents in the class. Information considered by the P&T Committee included, but was not limited to, sources of information listed in 32 C.F.R. 199.21(e)(2).

The macrolide cost effectiveness review was conducted as two discreet analyses. The first analysis considered only the erythromycin salts and base, while the second analysis compared the newer macrolides [azithromycin, Zmax (brand), clarithromycin, and telithromycin]. The first step for each evaluation utilized a cost-analysis to calculate the total weighted average cost per course of therapy for each agent. The second step was to conduct the appropriate pharmacoeconomic analysis taking into account the conclusions of the clinical review. Because the clinical review suggested minimal differences in clinical effectiveness (efficacy, safety, and tolerability) between the erythromycin salts and base, the appropriate pharmacoeconomic analysis for these agents was determined to be cost-minimization. However, a CEA was used to evaluate Zmax, azithromycin, clarithromycin, and telithromycin, because the clinical review suggested differences in clinical effectiveness (efficacy, safety, and tolerability) between these agents. Effectiveness differences between the agents were quantified through the use of a MAUT table.

Although the results of the erythromycin cost analysis (salts and base) determined erythromycin base to have the lowest total weighted average cost per course of therapy across all points of service (MTF, TRRx, TMOP), the cost effectiveness profiles for all the erythromycin agents were considered favorable.

The cost-analysis evaluation between azithromycin, Zmax, clarithromycin, and telithromycin determined azithromycin to have the lowest total weighted average cost per course of therapy across all points of service, followed by Zmax, clarithromycin, and telithromycin, respectively.

The CEA produced results with the same rank order, i.e, azithromycin being the most cost-effective followed by Zmax, clarithromycin and telithromycin.

The results of the above analyses were then incorporated into a BIA, which accounted for other factors and costs associated with a potential decision regarding formulary status of macrolide antibiotics within the UF. These factors included market share migration (due to changing provider prescribing practices), cost reduction associated with non-formulary status, and medical necessity processing fees. Switch costs were not included, because the macrolides were assumed to be used acutely rather than on a chronic basis. The results of the BIA confirmed the results of the preliminary analyses. Erythromycin and azithromycin (other than the Z-max formulation) were found to be the most cost-effective macrolide antibiotics overall. A sensitivity analysis conducted around the uncertainty of azithromycin prices due to its generic availability suggested that, as the price of generic azithromycin falls: 1), azithromycin becomes even more cost effective compared to other second generation macrolides; and 2) scenarios placing the branded Z-max formulation into the non-formulary tier become increasingly more cost beneficial to DoD.

Conclusion: The P&T Committee agreed (17 for, 0 against, 1 abstained, 1 absent) with the relative-cost effectiveness analyses presented for the macrolide antibiotics. Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of the macrolide antibiotics, the P&T Committee recommended that the status of telithromycin and the Zmax formulation of azithromycin be changed from formulary to non-formulary on the UF, with erythromycin (base and salts), clarithromycin immediate and extended release, and non-Zmax formulations of azithromycin maintaining formulary status on the UF with the formulary cost share.

COMMITTEE ACTION: The P&T Committee, based upon its collective professional judgment, voted (17 for, 0 opposed, 1 abstained, 1 absent) to recommend non-formulary status on the UF for telithromycin and the Zmax formulation of azithromycin, with erythromycin salts and base, all forms of clarithromycin, and non-Zmax formulations of azithromycin maintaining formulary status on the UF at the formulary cost share.

C. Macrolide/Ketolide UF Medical Necessity Criteria: Based on the clinical evaluation of macrolides and telithromycin and the conditions for establishing medical necessity for a non-formulary medication provided in the UF rule, the P&T Committee concluded that the following general medical necessity criteria would apply for these agents:

1) Use of a formulary macrolide (azithromycin, clarithromycin IR/ER, and erythromycin) is contraindicated, and the use of a non-formulary agent (Zmax and telithromycin) is not contraindicated.

2) The patient has experienced or is likely to experience significant adverse effects from formulary macrolides, and the patient is reasonably expected to tolerate a non-formulary agent.

3) Treatment with a formulary macrolide has resulted in a therapeutic failure, and the patient is reasonably expected to respond to a non-formulary agent. [Note: “Therapeutic failure” to be outlined on the medical necessity form].

4) There is no alternative formulary agent available. The patient may receive telithromycin if he/she has a recent history of documented MDRS, and cannot be treated with agents from other formulary antibiotic classes (e.g., quinolone antibiotics).

COMMITTEE ACTION: The DoD P&T Committee voted (17 for, 0 opposed, 1 abstained, 1 absent) to accept the macrolide/ketolide medical necessity criteria.

D. Macrolide/ketolide UF: Because of the low utilization of Zmax and telithromycin at the MTFs, and the fact that these agents, for the most part, are not used chronically, the Committee recommended an effective date no later than the first Wednesday following a 60-day implementation.

COMMITTEE ACTION: The DoD P&T Committee voted (16 for, 1 opposed, 1 abstained, 1 absent) to recommend an implementation period of 60 days.

E. Macrolide/Ketolide BCF Review and Recommendations: The P&T Committee reviewed the macrolides recommended for inclusion on the UF to select the BCF macrolide.

There are currently two macrolides on the BCF: azithromycin 250 mg tablet, and all formulations of erythromycin with the exception of erythromycin particles in tablets (PCE Dispertab) and erythromycin base delayed release capsule. From a clinical and economic standpoint, azithromycin 250 mg tablets and at least one erythromycin salt/ester are rational selections for the BCF. Azithromycin is the highest utilized macrolide in the entire MHS (MTF, TRRx, and TMOP), has a wide range of FDA indications, and is now generically available. Erythromycin has a wide variety of FDA indications, is efficacious for many different types of infections, has a niche in the treatment certain types of disorders/infections, is relatively low in cost compared to the other macrolides and telithromycin, and is generically available. Because of the large number of erythromycin formulations (base and salts), and no one erythromycin formulation has shown to have superior clinical efficacy over another, the individual MTFs can decide what erythromycin formulation should be added to their local formulary.

Conclusion: The Committee concurred with the recommendation to place azithromycin 250 mg tablet and one erythromycin salt/ester on the BCF.

COMMITTEE ACTION: The DoD P&T Committed voted (17 for, 0 opposed, 1 abstained, 1 absent) to recommend azithromycin 250 mg tablet, and one erythromycin (base or salt) as the BCF agent(s).

13. ANTI-MUSCARINIC OVER ACTIVEBLADDER MEDICATIONS

PEC staff presented a clinical review of the medications used for the treatment of overactive bladder disease. The agents in this class include oxybutynin chloride immediate release (Ditropan), extended release (Ditropan XL), and transdermal patches (Oxytrol); tolterodine tartrate immediate release (Detrol) and extended release (Detrol LA); trospium chloride (Sanctura); solifenacin succinate (VESIcare); and darifenacin hydrobromide (Enablex). The current BCF agents for this class are oxybutynin chloride immediate release and tolterodine tartrate extended release (Detrol LA). The BCF specifically excludes oxybutynin chloride extended release (Ditropan XL).

The Committee provided expert opinion regarding the key questions in this drug class and clinical outcomes of importance for the purpose of developing an appropriate cost effectiveness model. Both the clinical and cost effectiveness analyses will be completed during the February 2006 meeting; no action necessary.

13. ADJOURNMENT

The third day of the meeting adjourned at 1130 hours on November 18, 2005. The dates of the next meeting are February 14 – 16, 2006.

Appendix A – Table 1. Implementation Status of UF Decisions

Appendix B – Table 2. Newly Approved Drugs

Appendix C – Table 3. Abbreviations

Appendix A – Table 1. Implementation Status of UF Class Review Decisions

Meeting	Drug Class	Non-Formulary Medications	BCF/ ECF	BCF/ECF Medications	Status		
					Decision Date (DoD P&T Minutes signed)	**Effective Date of Decision**	**Comments**
Aug 05	Alpha Blockers for BPH	tamsulosin (Flomax)	BCF	terazosin alfuzosin (Uroxatral)	13 Oct 05	15 Feb 06 (120-day implementation period)	BCF selection effective 13 Oct 05; MTFs must have terazosin and alfuzosin on formulary.
Aug 05	CCBs	amlodipine (Norvasc) isradipine IR (Dynacirc) isradipine ER (Dynacirc CR) nicardipine IR (Cardene, generics) nicardipine SR (Cardene SR) verapamil ER (Verelan) verapamil ER for bedtime dosing (Verelan PM, Covera HS) diltiazem ER for bedtime dosing (Cardizem LA)	BCF	nifedipine ER (Adalat CC) verapamil SR diltiazem ER (Tiazac)	13 Oct 05	15 Mar 06 (150-day implementation period)	BCF selection effective 13 Oct 05; MTFs must have the CC formulation of nifedipine ER (Adalat CC or its generic equivalent) verapamil SR, and the Tiazac formulation of diltiazem ER on formulary.
Aug 05	ACE Inhibitors & ACE Inhibitor / HCTZ Combinations	moexipril (Univasc), moexipril / HCTZ (Uniretic) perindopril (Aceon) quinapril (Accupril) quinapril / HCTZ (Accuretic) ramipril (Altace)	BCF	captopril lisinopril lisinopril / HCTZ	13 Oct 05	15 Feb 06 (120-day implementation period)	BCF selection effective 13 Oct 05; MTFs must have captopril, lisinopril, and lisinopril HCTZ on formulary.
May 05	PDE-5 Inhibitors	sildenafil (Viagra) tadalafil (Cialis)	ECF	vardenafil (Levitra)	14 Jul 05	12 Oct 05 (90-day implementation period)	ECF selection effective 14 Jul 05. MTFs may add vardenafil to formulary based on local needs
May 05	Topical Antifungals*	econazole ciclopirox oxiconazole (Oxistat) sertaconazole (Ertaczo) sulconazole (Exelderm)	BCF	nystatin clotrimazole	14 Jul 05	17 Aug 05 (30-day implementation period)	BCF selection effective 14 Jul 05. MTFs must have nystatin and clotrimazole topical products on formulary.
May 05	MS-DMDs	-	ECF	interferon beta-1a intramuscular injection (Avonex)	14 Jul 05	-	ECF selection effective 14 Jul 05. MTFs must have Avonex on formulary if local needs necessitate having medications in this class on formulary.

Meeting	Drug Class	Non-Formulary Medications	BCF/ ECF	BCF/ECF Medications	Status		
					Decision Date (DoD P&T Minutes signed)	**Effective Date of Decision**	**Comments**
Feb 05	ARBs	eprosartan (Teveten) eprosartan/HCTZ (Teveten HCT)	BCF	telmisartan (Micardis) telmisartan/HCTZ (Micardis HCT)	18 Apr 05	17 Jul 05 (90-day implementation period)	BCF selection effective 18 Apr 05. MTFs must have telmisartan and telmisartan/HCTZ on formulary.
Feb 05	PPIs	esomeprazole (Nexium)	BCF	omeprazole rabeprazole (Aciphex)	18 Apr 05	17 Jul 05 (90-day implementation period)	BCF selection effective 18 Apr 05. MTFs must have omeprazole and rabeprazole on formulary.

BCF = Basic Core Formulary; ECF = Extended Core Formulary; ESI = Express-Scripts, Inc; MN = Medical Necessity; TMOP = TRICARE Mail Order Pharmacy;
TRRx = TRICARE Retail Pharmacy program; UF = UF
ER = extended release; IR = immediate release; SR = sustained release
ARBs = Angiotensin Receptor Blockers; ACE Inhibitors = Angiotensin Converting Enzyme Inhibitors; BPH = Benign Prostatic Hypertrophy; CCBs = Calcium Channel Blockers; HCTZ = hydrochlorothiazide; MS-DMDs = Multiple Sclerosis Disease-Modifying Drugs; PDE-5 Inhibitors = Phosphodiesterase-5 inhibitors; PPIs = Proton Pump Inhibitors
*The topical antifungal drug class excludes vaginal products and products for onychomycosis (e.g., ciclopirox topical solution [Penlac])

Appendix B – Table 2. Newly Approved Drugs Nov 2005 DoD P&T Committee Meeting

Medication & Mechanism of Action	FDA approval date; FDA-approved indications	Committee Recommendation
Pregabalin (Lyrica; Pfizer) capsules; GABA Analogue	Dec 04 (not launched until Sept 05): Lyrica is indicated for the management of neuropathic pain associated with diabetic peripheral neuropathy and postherpetic neuralgia. Lyrica is indicated as adjunctive therapy for adult patients with partial onset seizures	No UF recommendation at this meeting. Consideration of UF status deferred until drug class is reviewed.
Ramelteon tablets (Rozerem; Takeda); Selective melatonin receptor agonist (Non-benzodiazepine sedative hypnotic)	Jul 05 (launched in Sept 05); Ramelteon is indicated for the treatment of both chronic and transient insomnia characterized by difficulty with sleep onset.	No UF recommendation at this meeting. Consideration of UF status deferred until drug class is reviewed.
Mecasermin injection (Increlex; Tercica Pharmaceuticals); Recombinant human insulin-l-like growth factor-1 (IGF-1)	Aug 05 (anticipated launch in Jan 06); growth deficiency; Mecasermin is indicated for the long-term treatment of growth failure in children with severe primary IGF-1 deficiency (Primary IGFD) or with growth hormone (GH) gene deletion and have developed neutralizing antibodies to GH.	Prior Authorization recommended due to safety concerns (hypoglycemia) and the potential for misuse in patients with short stature. Consideration of UF status deferred until drug class is reviewed.
Mometasone furoate oral inhaler (Asmanex Twisthaler; Schering Plough); Oral inhaled corticosteroids	Mar 05 (launched in Jul 05); Asmanex Twisthaler is indicated for the maintenance of asthma as prophylactic therapy in patients 12 years of age or older. The Asmanex Twisthaler is also indicated for asthma patients who require oral corticosteroid therapy, where adding Asmanex Twisthaler therapy may reduce or eliminate the need for oral corticosteroids.	Quantity limits recommended due to existing precedence in the class. Consideration of UF status deferred until drug class is reviewed.
Omega 3 acid ethyl esters capsules (Omacor; Reliant Pharmaceuticals); Fish oil supplement	Nov 04 (launched Sep 05); Omacor is indicated as an adjunct to diet to reduce very high (>500 mg/dL) triglyceride levels in adults.	No UF recommendation at this meeting. Consideration of UF status deferred until drug class is reviewed.
Nepafenac ophthalmic solution 0.1% (Nevanac; Alcon); Ophthalmic NSAID	Aug 05 (launched Sept 05); Nevenac is indicated for the treatment of postoperative inflammation associated with cataract surgery.	No UF recommendation at this meeting. Consideration of UF status deferred until drug class is reviewed.

19 August 2005

DECISION PAPER:

AUGUST 2005 DoD PHARMACY AND THERAPEUTICS COMMITTEE RECOMMENDATIONS

1. CONVENING

2. ATTENDANCE

3. REVIEW MINUTES OF LAST MEETING

4. INTERIM DECISIONS/ADMINISTRATIVE ISSUES

5. ITEMS FOR INFORMATION

6. REVIEW OF RECENTLY APPROVED AGENTS

The Committee reviewed one new product in a class previously reviewed for Uniform Formulary (UF) status. Revatio is a new sildenafil product approved for the treatment of pulmonary arterial hypertension (also known as primary pulmonary hypertension). Unlike the other phosphodiesterase-5 inhibitor products (sildenafil (Viagra), tadalafil (Cialis), and vardenafil (Levitra)), Revatio is not approved for erectile dysfunction. Cialis and Viagra have been classified as non-formulary under the UF.

***COMMITTEE ACTION*:** The DoD Pharmacy and Therapeutics (P&T) Committee voted (17 for, 0 against, 0 abstained, 0 absent) to recommend that Revatio be added to the UF (see paragraph 6 on page 10 of P&T Committee minutes for rationale).

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

7. PRIOR AUTHORIZATION (PA) REQUIREMENT FOR PRAMLINTIDE (SYMLIN) INJECTION

The Committee agreed that a PA was needed for pramlintide (Symlin) subcutaneous injection due to safety issues.

***COMMITTEE ACTION*:** Based on the need for careful patient selection to ensure safety and effectiveness, the P&T Committee recommended (17 for, 0 against, 0 abstained, 0 absent) that PA be required for pramlintide (see paragraph 7 on pages 10 – 11 of P&T Committee minutes for rationale and summary of PA criteria).

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

***COMMITTEE ACTION*:** The Committee recommended that the PA for pramlintide should have an effective date no later than the first Wednesday following a 30-day implementation period. In order to avoid interruptions in therapy, the Committee recommended that patients who received pramlintide from a DoD pharmacy point of service prior to the PA effective date should be allowed to continue to receive pramlintide. The implementation period will begin immediately following the approval by the Director, TRICARE Management Activity (TMA).

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows:

8. ANGIOTENSIN CONVERTING ENZYME INHIBITOR (ACEI) DRUG CLASS REVIEW

The P&T Committee evaluated the relative clinical effectiveness and cost effectiveness of the ACEIs: benazepril (Lotensin and various generics), captopril (Capoten and various generics), enalapril (Vasotec and various generics), fosinopril (Monopril and various generics), lisinopril (Prinivil, Zestril, and various generics), trandolapril (Mavik), moexipril (Univasc), perindopril (Aceon), quinapril (Accupril), and ramipril (Altace), as well as their respective combinations with hydrochlorothiazide (HCTZ), if any. The ACEI class is in the top 10 of Military Health System (MHS) drug class expenditures at $75M annually.

A. COMMITTEE ACTION: The P&T Committee concluded (16 for, 0 against, 0 abstained, 1 absent) that all ACEIs are similar in terms of safety and tolerability profiles and in efficacy for hypertension. The P&T Committee recognized that there are differences in efficacy for myocardial infarction, heart failure, diabetic nephropathy and patients at high cardiovascular risk. These differences were incorporated into the cost-effectiveness analysis (CEA). The P&T Committee concluded that moexipril, perindopril, and quinapril were not cost-effective relative to the other ACEIs, since these agents were more costly and less effective. Although ramipril was shown to be more costly and more effective in the CEA, the P&T Committee did not value ramipril's clinical outcome evidence in high-risk cardiovascular patients enough to overcome its significantly higher cost (10-fold higher than the most cost-effective agent).

Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations for the ACEIs, and other relevant factors, the P&T committee recommended (16 for, 0 against, 0 abstained, 1 absent) that moexipril, perindopril, quinapril, and ramipril (and their respective combinations with HCTZ, if any) be classified as non-formulary under the UF, with benazepril, captopril, enalapril, fosinopril, lisinopril, and trandolapril (and their respective combinations with HCTZ, if any) remaining on the UF (see paragraphs 8A and 8B on pages 11 –15 of P&T Committee minutes for rationale).

Director, TMA, Decision: ■ Approved □ Disapproved

Approved, but modified as follows: "The Committee conducted a thorough review of the ACE inhibitor class of medications. One agent, Altace, was very carefully assessed. It provides clinical value to a small subset of beneficiaries, based on clinical trial criteria – HOPE trial. Applying medical necessity criteria, any MHS beneficiaries who meet HOPE trial criteria, will receive Altace, even following this formulary decision."

B. COMMITTEE ACTION: Based on the clinical evaluations of moexipril, perindopril, quinapril, and ramipril, and the conditions for establishing medical necessity for a non-formulary medication provided for in the UF rule, the P&T Committee recommended (15 for, 0 against, 0 abstained, 2 absent) medical necessity criteria for moexipril, perindopril, quinapril, and ramipril (and their respective combinations with HCTZ, if any). See paragraph 8C on pages 15 – 16 of P&T Committee minutes for criteria.

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

C. COMMITTEE ACTION: Because a substantial number of patients are currently receiving ramipril, moexipril, perindopril, or quinapril, the P&T Committee recommended (16 for, 0 against, 0 abstained, 1 absent) an effective date no later than the first Wednesday following a 120-day implementation period. The implementation period will begin immediately following the approval by the Director, TMA (see paragraph 8D on page 16 of P&T Committee minutes for rationale).

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

D. COMMITTEE ACTION: Based on the relative clinical and cost effectiveness analyses, the P&T Committee voted (15 for, 0 against, 1 abstained, 1 absent) to recommend lisinopril, lisinopril/HCTZ, and captopril as the Basic Core Formulary (BCF) agents (see paragraph 8E on pages 16 – 17 of P&T Committee minutes for rationale).

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

9. CALCIUM CHANNEL BLOCKER (CCB) DRUG CLASS REVIEW

The P&T Committee evaluated the relative clinical effectiveness of the nine CCBs marketed in the U.S.: the dihydropyridines nifedipine (Procardia, Adalat CC, and various generics), nicardipine (Cardene and Cardene SR), isradipine (DynaCirc and DynaCirc SR), felodipine (Plendil and various generics), amlodipine (Norvasc), nisoldipine (Sular), and nimodipine (Nimotop); and the non-dihydropyridines diltiazem (Cardizem, Cardizem CD, Cardizem LA, Tiazac, and various generics) and verapamil (Verelan, Verelan PM, Covera HS, Calan, Calan SR, and various generics). (See Table 3, Appendix C for a full listing of the CCBs that were

evaluated.) CCBs have extensive use in all DoD pharmacy points of service and a rank of 9th ($121M) in terms of total MHS drug expenditures.

A. COMMITTEE ACTION: The P&T Committee concluded (16 for, 0 against, 0 abstained, 1 absent) that (1) all eight CCBs have similar relative clinical effectiveness for treating hypertension; (2) that there is insufficient evidence to conclude that any one of the following CCBs (verapamil, diltiazem, nifedipine, amlodipine, nisoldipine, nicardipine, or isradipine) is superior for reducing risk of cardiovascular outcomes in patients with hypertension, and that there is no evidence for felodipine; (3) that there is no evidence of a difference in improving symptoms of angina with amlodipine, nifedipine, diltiazem, nisoldipine, nicardipine, or verapamil, and that there is no evidence for felodipine or isradipine; (4) that amlodipine and felodipine do not adversely or positively affect mortality or morbidity in patients with systolic dysfunction; (5) that there is insufficient evidence to clearly differentiate the CCBs on the basis of adverse events, and that the overall incidence of edema ranges between 8-10%; and (6) none of the CCBs can be designated as non-formulary under the UF based solely on the clinical evidence.

The P&T concluded (17 for, 0 against, 0 abstained, 0 absent) that isradipine immediate release and isradipine controlled release, nicardipine immediate release and nicardipine sustained release, amlodipine, Verelan, Verelan PM, Covera HS, and Cardizem LA were not cost-effective compared to nifedipine immediate release, nifedipine extended release, felodipine, nisoldipine, verapamil immediate release, verapamil sustained release, diltiazem immediate release, diltiazem sustained release, and diltiazem extended release. Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of the CCBs, the P&T Committee voted (17 for, 0 against, 0 abstained, 0 absent) to recommend formulary status for nifedipine immediate release, nifedipine extended release, felodipine, nimodipine, nisoldipine, verapamil immediate release, verapamil sustained release, diltiazem immediate release, diltiazem sustained release, and diltiazem extended release, and non-formulary status for isradipine immediate release and isradipine controlled release, nicardipine immediate release and nicardipine sustained release, amlodipine, Verelan, Verelan PM, Covera HS, and Cardizem LA. Nifedipine immediate release and nimodipine are not therapeutic alternatives to the other CCBs, as they are not used for cardiovascular conditions (see paragraph 9A & B on pages 17 – 24 of P&T Committee minutes for rationale).

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

B. COMMITTEE ACTION: Based on the clinical evaluations of isradipine immediate release and isradipine controlled release, nicardipine immediate release and nicardipine sustained release, amlodipine, Verelan, Verelan PM, Covera HS, and Cardizem LA, and the conditions for establishing medical necessity for a non-formulary medication provided for in the UF rule, the P&T Committee recommended (17 for, 0 against, 0 abstained, 0 absent) medical necessity criteria for the isradipine immediate release and isradipine controlled release, nicardipine

immediate release and nicardipine sustained release, amlodipine, Verelan, Verelan PM, Covera HS, and Cardizem LA (see paragraph 9C on page 25 of P&T Committee minutes for criteria).

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

C. COMMITTEE ACTION: Because a substantial number of patients are currently using a CCB recommended for non-formulary status on the UF (268,00 patients, 73% of MHS patients receiving CCBs), the P&T Committee recommended (16 for, 0 opposed, 0 abstained, 1 absent) an effective date no later than the first Wednesday following a 150-day implementation period. The implementation period will begin immediately following the approval by the Director, TMA (see paragraph 9D on page 25 of P&T Committee minutes for rationale.)

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

D. COMMITTEE ACTION: Based on the relative clinical and cost effectiveness analyses, the P&T Committee recommended placing nifedipine extended release (vote: 17 for, 0 opposed, 0 abstained, 0 absent); verapamil sustained release (vote: 17 for, 0 opposed, 0 abstained, 0 absent), and diltiazem extended release (vote: 17 for, 0 opposed, 0 abstained, 0 absent) on the BCF. (See paragraph 9A and 9B on pages 17 – 24 of P&T Committee minutes for rationale.)

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

10. ALPHA BLOCKERS FOR BENIGN PROSTATIC HYPERTROPHY (BPH) DRUG CLASS REVIEW

The P&T Committee evaluated the relative clinical effectiveness and cost effectiveness of the alpha blockers used to treat BPH. Four agents were considered in the review, and were classified as either selective or non-selective based upon the agent's target receptor subtype. The two non-selective agents considered in the review were doxazosin (Cardura and various generics) and terazosin (Hytrin and various generics). The two selective agents were alfuzosin (Uroxatral) and tamsulosin (Flomax). There has been an increase in the use of selective BPH alpha blockers over the past several years resulting in the entire class (selective and non-selective) being ranked 32nd in terms of annual MHS drug class expenditures at $38M.

A. COMMITTEE ACTION: The P&T Committee concluded (16 for, 0 against, 0 abstained, 1 absent) that none of the alpha blockers have a significant clinically meaningful therapeutic

advantage in terms of efficacy over other alpha blockers; however, the selective agents may have a marginal benefit over the non-selective agents with respect to safety and tolerability. Within subgroups, the two non-selective agents (doxazosin and terazosin) were found to be similar in terms of cost-effectiveness; however, tamsulosin was found not to be cost-effective relative to alfuzosin in the selective alpha blocker sub-class. Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations for the BPH alpha blockers, and other relevant factors, the P&T Committee recommended (16 for, 0 against, 0 abstained, 1 absent) that tamsulosin be classified as non-formulary under the UF, and that doxazosin, terazosin, and alfuzosin be classified as formulary under the UF (see paragraphs 10A and 10B on pages 25 – 28 of P&T Committee minutes for rationale).

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

B. COMMITTEE ACTION: Based on the clinical evaluations of tamsulosin, and the conditions for establishing medical necessity for a non-formulary medication provided for in the UF rule, the P&T Committee recommended (16 for, 0 against, 0 abstained, 1 absent) medical necessity criteria for tamsulosin (see paragraph 10C on page 28 of P&T Committee minutes for criteria).

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

C. COMMITTEE ACTION: Because a substantial number of patients are currently receiving tamsulosin from one of the three MHS pharmacy points of service (89,926 patients, 46% of all patients receiving alpha blockers), the P&T Committee recommended (16 for, 0 against, 0 abstained, 1 absent) an effective date no later than the first Wednesday following a 120-day implementation period. The implementation period will begin immediately following the approval by the Director, TMA (see paragraph 10D on pages 28 – 29 of P&T Committee minutes for rationale).

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

D. COMMITTEE ACTION: Based on the relative clinical and cost effectiveness analyses, the P&T Committee voted (16 for, 0 against, 0 abstained, 1 absent) to recommend terazosin and alfuzosin as the BCF agents (see paragraph 10E on page 29 of P&T Committee minutes for rationale).

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

11. ANTIDEPRESSANTS (EXCLUDING MONOAMINE OXIDASE INHIBITORS AND TRICYCLIC ANTIDEPRESSANTS)

Portions of the clinical review were presented to the Committee. The Committee provided expert opinion regarding clinical outcomes of importance for the purpose of developing an appropriate cost-effectiveness model. Both the clinical and economic analyses will be completed during the November 2005 meeting; no action necessary.

12. CHOLINESTERASE AND N-METHYL D-ASPARTATE (NMDA) INHIBITORS FOR ALZHEIMER'S DISEASE

Portions of the clinical review were presented to the Committee. The Committee provided expert opinion regarding clinical outcomes of importance for the purpose of developing an appropriate cost-effectiveness model. Both the clinical and economic analyses will be completed during the November 2005 meeting; no action necessary.

Date: 13 October 2005

Department of Defense
Pharmacy and Therapeutics Committee Minutes

19 August 2005

1. CONVENING

The DoD Pharmacy and Therapeutics (P&T) Committee convened at 0800 hours on 17, 18, and 19 August 2005 at the DoD Pharmacoeconomic Center (PEC), Fort Sam Houston, Texas.

2. ATTENDANCE

A. Voting Members Present

CAPT Patricia Buss, MC, USN	DoD P& T Committee Chair
CDR Mark Richerson, MSC, USN	DoD P& T Committee Recorder
MAJ Travis Watson, MS, USA	Alternate, DoD Pharmacy Programs, TMA
Maj Michael Proffitt, MC	Air Force, OB/GYN Physician
Maj Nicholas Conger, MC	Air Force, Internal Medicine Physician
Lt Col Everett McAllister, BSC	Air Force, Pharmacy Officer
Lt Col Brian Crownover, MC	Air Force, Physician at Large
LCDR Roger Akins, MC	Navy, Pediatrics Physician
CDR Brian Alexander, MC	Navy, Physician at Large
CAPT David Price, MSC	Navy, Pharmacy Officer
COL Doreen Lounsbery, MC	Army, Internal Medicine Physician
MAJ Roger Brockbank, MC	Army, Family Practice Physician
COL Joel Schmidt, MC	Army, Physician at Large
COL Isaiah Harper, MS	Army, Pharmacy Officer
CDR Vernon Lew, USPHS	Coast Guard, Pharmacy Officer
LTC Donald DeGroff, MS, USA	Contracting Officer Representative, TMOP
CDR Jill Pettit, MSC, USN	Contracting Officer Representative, TRRx

B. Voting Members Absent

CDR William Blanche, MSC	Director, DoD Pharmacy Programs, TMA
LCDR Chris Hyun, MC	Navy, Internal Medicine Physician
Joe Canzolino	Department of Veterans Affairs

C. Non-Voting Members Present

Lynn T. Burleson	Assistant General Counsel, TMA
Martha Taft	Resource Management Directorate, TMA
Capt Peter Trang, BSC, USAF	Defense Supply Center Philadelphia

D. Non-Voting Members Absent

COL Kent Maneval, MS, USA	Defense Medical Standardization Board

E. Others Present

Col Gregory Wickern, MC	Air Force, Alternate for Internal Medicine (present only 19 August)
Mr. Dan Remund	DoD Pharmacoeconomic Center (present only 17 August)
CDR Denise Graham, MSC, USN	DoD Pharmacoeconomic Center
CAPT Donald Nichols, MC, USN	DoD Pharmacoeconomic Center
Lt Col David Bennett, BSC, USAF	DoD Pharmacoeconomic Center
Lt Col Barbara Roach, MC, USAF	DoD Pharmacoeconomic Center
Lt Col James McCrary, MC, USAF	DoD Pharmacoeconomic Center (present 18 & 19 August)
Maj Wade Tiller, BSC, USAF	DoD Pharmacoeconomic Center
CPT Jill Dacus, MC , USA	DoD Pharmacoeconomic Center
CPT Ryan Young, USA	Reservist, Assigned to DoD Pharmacoeconomic Center
Shana Trice	DoD Pharmacoeconomic Center
David Bretzke	DoD Pharmacoeconomic Center
Angela Allerman	DoD Pharmacoeconomic Center
Eugene Moore	DoD Pharmacoeconomic Center
Julie Liss	DoD Pharmacoeconomic Center
Elizabeth Hearin	DoD Pharmacoeconomic Center
Dave Flowers	DoD Pharmacoeconomic Center
David Meade	DoD Pharmacoeconomic Center
Harsha Mistry	DoD Pharmacoeconomic Center
SFC Daniel Dulak, USA	DoD Pharmacoeconomic Center
Francine Goodman	Department of Veterans Affairs

3. REVIEW MINUTES OF LAST MEETING

Dr. William Winkenwerder, Jr., M.D. approved the minutes of the May 2005 DoD P&T Committee on 14 July 2005.

4. INTERIM DECISIONS/ADMINISTRATIVE ISSUES

A. DoD P&T Committee Charter – CAPT Buss reported that the charter has been changed to provide for the following: Each voting member and non-voting member may have a designated alternate who can represent the member, including voting (if representing a voting member), at P&T Committee meetings in the event the member cannot attend.

5. ITEMS FOR INFORMATION

TRICARE Management Activity (TMA) and DoD PEC staff members briefed the P&T Committee on the following:

A. Beneficiary Advisory Panel (BAP) Briefing: TMA briefed the members of the DoD P&T committee regarding the 27 June 2005 BAP meeting. The Committee was briefed on BAP comments regarding DoD P&T Committee's Uniform Formulary (UF) and implementation recommendations.

B. Implementation Status of UF Decisions: PEC staff and TMA briefed the members of the Committee on the implementation status of UF decisions arising from the February and May 2005 meetings (see Table 1, Appendix A). The Committee noted that the five drug classes reviewed at the February and May 2005 meetings represent 12% of total Military Health System (MHS) drug spend dollars. These five drug classes plus the four drug classes covered by existing pharmaceutical contracts represent 30% of all MHS drug spend dollars.

6. REVIEW OF RECENTLY-APPROVED AGENTS

The PEC presented clinical information on five new medications approved by the U.S. Food and Drug Administration (FDA), and introduced to the U.S. market since February 2005 (see Table 2, Appendix B). Four of the five medications fall into drug classes not yet reviewed by the DoD P&T Committee; therefore, UF consideration of these medications was deferred until drug class reviews are completed.

The fifth medication is a new sildenafil product that is FDA-approved for the treatment of pulmonary arterial hypertension (also known as primary pulmonary hypertension (PPH)) and marketed under the name of Revatio. Revatio is supplied as a 20-mg tablet, and must be given three times daily for the treatment of PPH; it is not approved for erectile dysfunction. Viagra, which is approved only for erectile dysfunction, is available in 25-, 50-, and 100-mg tablets. Viagra (sildenafil) and a similar medication, Cialis (tadalafil), are non-formulary under the UF.

Since the phosphodiesterase-5 (PDE-5) inhibitors were reviewed in May 2005, the Committee considered Revatio to be a newly-approved medication in a previously reviewed drug class. The Committee considered the following issues with regard to Revatio:

- Existing medical necessity criteria for Viagra allow reduction of the non-formulary cost share to the formulary cost share in patients with PPH.
- The clinical and cost effectiveness of Revatio relative to other medications used for the treatment of this rare, serious condition (e.g., eproprostenol, treprostinil, bosentan).

***COMMITTEE ACTION*:** The Committee voted (17 for, 0 against, 0 abstained, 0 absent) to recommend that Revatio be added to the UF. The Committee decided not to recommend a change in existing prior authorization (PA) criteria for Viagra to preclude its use for PPH, since some patients may be stabilized on Viagra.

The Committee noted that PA requirements previously established for the PDE-5 inhibitor drug class apply to Revatio. A PA is required for all patients receiving sildenafil (Revatio or Viagra) for PPH.

Since all patients receiving Revatio must meet PA requirements, the Committee did not recommend a specific quantity limit for Revatio. Quantity limits for Cialis, Levitra, and Viagra for the treatment of erectile dysfunction (combined limit of 6 units per 30 days, or 18 per 90 days) continue to apply at all DoD points of service.

7. PA REQUIREMENTS FOR PRAMLINTIDE (SYMLIN) INJECTION

At the May 2005 meeting, the Committee discussed the potential need for a PA requirement for pramlintide (Symlin) subcutaneous injection, and requested that the PEC develop PA criteria to be reviewed at the next meeting. Pramlintide, which is used with insulin by diabetic patients to improve blood glucose control after meals, presents some unique concerns regarding appropriate patient selection, dosing, administration, potential for interaction with other medications, and required adjustment of insulin dosing due to the potential for severe

hypoglycemia. Labeling for pramlintide includes specific recommendations for patient selection. Pramlintide should only be used by patients who have not reached their blood glucose goals despite managing their insulin therapy and diet well, monitoring blood glucose as directed, and following up with their providers on a regular basis. Patients using pramlintide must understand how to adjust pramlintide and insulin doses and be able to recognize hypoglycemia. Pramlintide is not indicated for use in pediatric patients.

***COMMITTEE ACTION*:** Based on the need for careful patient selection to ensure safety and effectiveness, the P&T Committee recommended that a PA be required for pramlintide (17 for, 0 against, 0 abstained, 0 absent). The Committee recommended that the PA should have an effective date no later than the first Wednesday following a 30-day implementation period. In order to avoid interruptions in therapy, which would require adjustments in insulin dosage, and potentially cause disruptions in blood glucose control for patients stabilized on therapy, the Committee further recommended that patients who received pramlintide from a DoD pharmacy point of service prior to the PA effective date should be allowed to continue to receive pramlintide. The implementation period will begin immediately following the approval by the Director, TMA.

The Committee agreed that the following PA criteria should apply (17 for, 0 against, 0 abstained, 0 absent). PA approvals would be valid indefinitely.

Coverage is provided for the use of pramlintide as an adjunct treatment in type 1 and type 2 diabetic patients 18 or older who use mealtime insulin therapy and who meet all of the following criteria:

- are currently on insulin
- have a glycosylated hemoglobin (HbA1c) $\leq$ 9%
- are monitoring blood glucose levels frequently (at least 3 or more times per day)
- have failed to achieve adequate control of blood glucose levels despite individualized management of their insulin therapy
- are receiving ongoing care under the guidance of a health care provider skilled in use of insulin and supported by the services of a diabetic educator

Coverage is not provided for patients who:

- have poor adherence to their current insulin regimen or blood glucose monitoring
- have a HbA1c > 9%
- have experienced recurrent severe hypoglycemia requiring assistance within the past 6 months
- have experienced the presence of hypoglycemia unawareness
- have a confirmed diagnosis of gastroparesis or require the use of drugs to stimulate gastrointestinal motility

8. ANGIOTENSIN CONVERTING ENZYME INHIBITOR (ACEI) DRUG CLASS REVIEW

A. ACEI UF Relative Clinical Effectiveness: The Committee evaluated the relative clinical effectiveness of the ten ACEIs marketed in the U.S.: benazepril (Lotensin and various generics), captopril (Capoten and various generics), enalapril (Vasotec and various generics), fosinopril (Monopril and various generics), lisinopril (Prinivil, Zestril, and various generics), trandolapril (Mavik), moexipril (Univasc), perindopril (Aceon), quinapril (Accupril), and ramipril (Altace) and their respective combinations with hydrochlorothiazide (HCTZ). Perindopril, ramipril, and trandolapril are not available in combination with HCTZ.

Information regarding the safety, effectiveness, and clinical outcome of these drugs was considered. The clinical review included, but was not limited to the requirements stated in the UF Rule, 32 CFR 199.21.

1) *Safety and Tolerability:* The most common or serious adverse effects of the ACEIs are hypotension, dry cough, angioedema, hyperkalemia, rash, and acute renal impairment. Doses of captopril >100 mg have been associated with neutropenia and dysgeusia. Head to head trials of the ACEIs in hypertension, myocardial infarction (MI), and heart failure reported withdrawal rates due to adverse events ranging from 0-39%, but there were no significant differences between the ACEIs in any trial.

   Conclusion: The DoD P&T Committee concluded that there is no evidence that any ACEI is associated with a lower risk of serious complications than any other ACEI.

2) *Efficacy for Hypertension*: All ten ACEIs are approved by the FDA for treating hypertension. All ACEIs reduce blood pressure when titrated to effect.

   Conclusion: The Committee agreed that there is no evidence that any one ACEI is more efficacious than the others for lowering blood pressure.

3) *Efficacy in High Cardiovascular Risk patients:* The Committee agreed that evidence of a favorable effect on clinical outcomes (i.e., irreversible outcomes such as death, MI, stroke, need for dialysis or renal transplantation) is more important than evidence of favorable effects on physiologic outcomes (i.e., reversible outcomes that are surrogate markers of disease, such as changes in lab values).

   Three ACEIs have been evaluated in large, well-conducted randomized trials enrolling more than 8,000 high cardiovascular risk patients. In the HOPE trial, ramipril 10 mg was found to reduce the incidence of cardiovascular death, all-cause death and cardiovascular events in diabetic and non-diabetic patients with severe coronary artery disease, compared with placebo. The use of appropriate background medications such as statins, aspirin, and beta blockers was low in this study. In the EUROPA trial, perindopril 8 mg reduced the incidence of cardiovascular events (non-fatal MI, unstable angina), but did not show a benefit in reducing mortality in patients with stable coronary artery disease. The PEACE trial, where trandolapril 4 mg was evaluated in patients with stable coronary artery disease, did not show a benefit of the ACEI in reducing mortality or cardiovascular events. A large percentage of patients in the PEACE trial were receiving appropriate background therapy, and > 50% had prior coronary artery bypass grafting or percutaneous transluminal coronary angioplasty.

   Ramipril when used at doses of 5-10 mg has shown a benefit in reducing cardiovascular events but not mortality in one trial enrolling 617 patients (PART-2 trial); however, no reduction in cardiovascular events was seen when ramipril doses of 1.25 mg were evaluated (DIABHYCAR trial). Quinapril was studied in one trial of 1700 patients, but no reduction in cardiovascular events was reported (QUIET trial). A small trial (229 patients) with enalapril administered with simvastatin reported a reduction in cardiovascular events.

   In DoD, it is estimated that approximately 10% of the patients receiving ramipril meet the entry criteria established for the HOPE trial, e.g., patients with a history of cardiovascular disease (coronary artery disease, stroke, peripheral vascular disease, or diabetes), and one additional risk factor, including smoking, hypertension, hyperlipidemia, or renal insufficiency.

Conclusion: The Committee agreed that in patients with high cardiovascular risk, ramipril 10 mg is the only ACEI reported to have shown a reduction in both mortality and cardiovascular events, based on the HOPE trial. Perindopril 8 mg (EUROPA), and simvastatin have shown a reduction in major cardiovascular events, but not mortality in patients with coronary artery disease. A large trial with trandolapril did not show a reduction in major cardiovascular events, but the use of appropriate background medications was high. Quinapril has also not shown a benefit in reducing cardiovascular events.

4) *Recent MI:* Placebo-controlled trials evaluating the use of ACEIs after an MI have shown a reduction in mortality with captopril, lisinopril, ramipril, and trandolapril. Enalapril and fosinopril have shown reductions in hospitalizations for heart failure.

   Conclusion: In patients following an MI, a mortality benefit has been documented with captopril, lisinopril, ramipril, and trandolapril.

5) *Chronic Heart Failure:* A meta-analysis of 32 placebo-controlled trials enrolling over 9,000 patients reported similar point estimates for a mortality reduction with benazepril, captopril, enalapril, lisinopril, perindopril, quinapril, and ramipril. When the meta-analysis was published (1995), there was limited evidence with benazepril and perindopril, and no evidence with moexipril or trandolapril. The American College of Cardiology (ACC) and American Heart Association (AHA) guidelines for treating heart failure state that the best evidence for a mortality reduction in patients with heart failure is with captopril, enalapril, ramipril, and trandolapril, as the dosage is known for these ACEIs.

   Conclusion: In patients with chronic heart failure, the best evidence for a mortality benefit has been documented with captopril, enalapril, lisinopril, ramipril, and trandolapril.

6) *Diabetic and Non-Diabetic Renal Disease:*

   Type 1 Diabetic Nephropathy: Captopril is the only ACEI approved for diabetic nephropathy, based on one long-term trial (Collaborative trial) evaluating clinical endpoints (development of end-stage renal disease and death). Lisinopril, ramipril, perindopril, and enalapril have shown benefits in reducing proteinuria, but have not been shown to prevent progression of renal failure in type 1 diabetic patients.

   Type 2 Diabetic Nephropathy: A study of ramipril 1.25 mg in type 2 diabetics with nephropathy that evaluated both cardiovascular and renal outcomes did not show a benefit over placebo, but a reduction in albumin excretion rate was noted. A trial with benazepril 10 mg in type 2 diabetic patients did show a reduction in doubling of serum creatinine and need for dialysis; however, this benefit was seen in only 21 patients. A benefit on surrogate outcomes (reduction of microalbuminuria) has been seen with enalapril, lisinopril quinapril, and ramipril.

   Non-Diabetic Renal Disease: Captopril, enalapril, benazepril, and ramipril have been shown in one meta-analysis to reduce the risk of end-stage renal disease in non-diabetic patients with renal insufficiency.

   Conclusion: For type 1 diabetic nephropathy, captopril reduced the risk of end stage renal disease and death in poorly controlled patients. Enalapril, lisinopril, ramipril, and perindopril reduce microalbuminuria, but have not been shown to reduce the risk of end stage renal disease in type 1 diabetes mellitus (DM). For type 2 diabetic nephropathy, no ACEI has shown a benefit on clinical outcomes. Lisinopril, enalapril, quinapril, ramipril

and trandolapril appear beneficial based on various surrogate markers of renal disease, but have not been shown to impact clinical outcomes in type 2 DM. In patients with non-diabetic nephropathy, benazepril, ramipril, enalapril, captopril, and enalapril have shown a reduction in clinical outcomes.

7) *Prevention of DM:* Subgroup analysis from large trials conducted with enalapril, captopril, and ramipril has shown a delay or prevention of the development of diabetes. An ongoing trial with ramipril and rosiglitazone (DREAM trial) is underway that will prospectively evaluate whether treatment with an ACEI or thiazolidinedione will delay the development of type 2 DM.

   Conclusion: Post-hoc studies with enalapril, captopril, and ramipril have shown a delay or prevention of DM, but this has not been proven in a prospectively designed trial.

Clinical Effectiveness Conclusion: The Committee concluded that (1) all ten ACEIs have similar relative clinical effectiveness for treating hypertension; (2) ramipril has shown a reduction in mortality in patients at high cardiovascular risk; (3) captopril, enalapril, ramipril, lisinopril and trandolapril have the best evidence for reducing mortality in chronic heart failure and following MI; (4) captopril has the best evidence for improving clinical outcomes in type 1 diabetic renal disease; (5) no ACEI has shown a benefit in improving clinical outcomes in type-2 diabetic disease; (6) benazepril, ramipril, enalapril, and captopril show the best evidence for improving clinical outcomes in non-diabetic renal disease; and (7) no ACE is preferable relative to another in terms of adverse events.

Two alternative methods were used for comparing ACEIs on clinical effectiveness. When DoD utilization, therapeutic overlap and quality of evidence for various conditions were considered, ramipril, lisinopril, captopril, fosinopril, benazepril, and enalapril had higher clinical utility (overall clinical usefulness) relative to quinapril, perindopril, trandolapril, and moexipril. When using another model which only evaluated quality of evidence, the resulting ranking (from highest to lowest utility) was: ramipril, trandolapril, enalapril, perindopril, captopril, lisinopril, fosinopril, quinapril, benazepril, and moexipril. The Committee considered both evaluations when formulating their recommendation.

The Committee concluded that ramipril, captopril, lisinopril, benazepril, enalapril, trandolapril, and fosinopril have increased clinical effectiveness relative to moexipril, quinapril, and perindopril.

COMMITTEE ACTION: The Committee voted (16 for, 0 opposed, 0 abstained, 1 absent) to accept the clinical effectiveness conclusion as stated above.

B. ACEI UF Relative Cost Effectiveness: The P&T Committee evaluated the relative cost-effectiveness of the ACEIs in relation to safety, tolerability, effectiveness, and clinical outcomes of the other agents in the class. Information considered by the P&T Committee included but was not limited to sources of information listed in 32 CFR 199.21(e)(2).
To determine the relative cost effectiveness of the ACEIs, two separate economic analyses were performed: a pharmacoeconomic analysis, and a budget impact analysis (BIA). From the preceding relative clinical effectiveness evaluation, the P&T Committee determined that ACEIs have similar safety and tolerability, and similar relative clinical effectiveness in the treatment of hypertension. However the ACEIs differ in clinical outcome evidence supporting their effectiveness in patients with high cardiovascular risk, post MI, heart failure, type 1 DM mellitus, type 2 DM mellitus, and non-diabetic nephropathy patients. In other words, the agents were shown to differ in relative clinical effectiveness.

First, a cost-minimization analysis (CMA) was performed to stratify the agents solely on cost. The results of the CMA revealed three distinct clusters along the cost-continuum: low, moderate, and high cost agents. The low cost cluster included benazepril, captopril, enalapril, and lisinopril, whereas the moderate cost cluster included fosinopril and trandolapril. Moexipril, perindopril, quinapril, and ramipril were included in the high cost cluster.

Given this conclusion, the relative cost effectiveness of the agents was determined through a cost-effectiveness analysis (CEA). In this type of analysis, agents within a therapeutic class are competed on two dimensions, cost and effect (outcomes). The cost used in the analysis was the total weighted average cost per day of treatment (for all three points of service). The effectiveness measure used for each agent was the composite score derived from the clinical effectiveness analysis that ranked the agents based on clinical outcome evidence. The results of the CEA were: captopril was the most cost-effective agent, followed by enalapril; lisinopril and benazepril, trandolapril, and ramipril were more effective but more costly; and the other agents were less cost effective.

The results of the CMA and CEA were subsequently incorporated into a BIA. A BIA accounts for other factors and costs associated with a potential decision to recommend that one or more ACEIs be classified as non-formulary, such as market share migration, cost reduction associated with non-formulary cost shares, and medical necessity processing fees. The goal of the BIA was to identify a group of ACEIs to be included on the UF which best met the majority of the clinical needs of the DoD population at the lowest cost to the MHS. The BIA results revealed that a group of ACEIs that included benazepril, captopril, enalapril, fosinopril, lisinopril, and trandolapril best achieved this goal when compared to other combination groups of ACEIs, and thus were determined to be more cost-effective relative to other combination groups.

Conclusion: The P&T Committee, based upon its collective professional judgment, voted (17 for, 0 opposed, 0 abstained, 0 absent) to accept the ACEI cost-analysis presented by the PEC. The P&T Committee concluded that moexipril, perindopril, and quinapril were not cost-effective relative to the other ACEIs, since the agents were more costly and less effective. In pharmacoeconomic terms, these agents are considered to be "dominated." Although ramipril was shown to be more costly and more effective in the CEA, the P&T Committee did not value ramipril's clinical outcome evidence in high-risk cardiovascular patients enough to overcome its significantly higher cost (10-fold higher than the most cost-effective agent). Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of the ACEIs, and other relevant factors, the P&T Committee recommended that moexipril, perindopril, quinapril, and ramipril be classified as non-formulary under the UF and that benazepril, captopril, enalapril, fosinopril, lisinopril, and trandolapril be classified as formulary on the UF.

COMMITTEE ACTION: The P&T Committee, based upon its collective professional judgment, voted (17 for, 0 opposed, 0 abstained, 0 absent) to recommend that moexipril, perindopril, quinapril, and ramipril (and their respective combinations with HCTZ, if any) be classified as non-formulary under the UF, with benazepril, captopril, enalapril, fosinopril, lisinopril, and trandolapril (and their respective combinations with HCTZ, if any) remaining on the UF.

C. ACEI UF Medical Necessity Criteria: Based on the clinical evaluation of the ACE inhibitors and the conditions for establishing medical necessity for a non-formulary medication provided

for in the UF rule, the P&T Committee concluded that the following general medical necessity criteria would apply for these agents:

1.) Use of the formulary ACEIs (lisinopril, enalapril, captopril, benazepril, fosinopril, and trandolapril) is contraindicated, and the use of a nonformulary ACEI (ramipril, moexipril, quinapril, or perindopril) is not contraindicated.

2). The patient has experienced or is likely to experience significant adverse effects from the formulary ACEIs, and the patient is reasonably expected to tolerate a non-formulary ACEI.

3) Use of the formulary ACEI resulted in therapeutic failure, and the patient is reasonably expected to respond to a non-formulary ACEI, i.e., therapeutic failure as outlined on medical necessity form.

4) The patient has previously responded to a non-formulary ACEI, and changing to a formulary ACEI would incur unacceptable risk.

5) There is no alternative pharmaceutical agent on the formulary.

The Committee noted that criteria 4 and 5 would reasonably apply only to a small subset of patients receiving ACEIs, such as patients at high cardiovascular risk similar to those included in the HOPE trial.

COMMITTEE ACTION: The Committee voted (15 for, 0 opposed, 0 abstained, 2 absent) to accept the ACEI medical necessity criteria.

D. ACEI UF Implementation Plan: Because a substantial number of patients (158,000, or 21% of all patients receiving ACEIs) are currently receiving ramipril, moexipril, perindopril, or quinapril, the P&T Committee recommended an effective date no later than the first Wednesday following a 120-day implementation period. The implementation period will begin immediately following the approval by the Director, TMA

COMMITTEE ACTION: The Committee voted (16 for, 0 opposed, 0 abstained, 1 absent) to recommend an implementation period of 120 days.

E. ACE Inhibitor Basic Core Formulary (BCF) Review and Recommendations: The P&T Committee reviewed the ACEIs recommended for inclusion on the UF to select the BCF ACEIs. It had previously been decided that at least two, but no more than three ACEIs, would be added to the BCF, based on the outcome of relative clinical effectiveness and relative cost effectiveness determinations.

There are currently two ACEIs on the BCF: captopril and lisinopril. From a clinical and economic standpoint, captopril and lisinopril are rational selections for the BCF. Lisinopril is the highest utilized ACEI in the entire MHS (military treatment facility (MTF), TRICARE Retail Pharmacy (TRRx) program, and TRICARE Mail Order Pharmacy (TMOP)), has a wide range of FDA indications, is generically available, and has mortality data for heart failure and following MI. Captopril has a wide range of FDA indications, has mortality data for heart failure and following MI, has outcomes evidence in type 1 diabetic renal disease, is generically available, and has a short half-life which is good for titrating patients in the immediate post-MI setting and in frail patients.

Since no BCF prices were submitted for any of the ACEIs, the DoD P&T Committee evaluated the relative cost-effectiveness for BCF selection based on the cost-effectiveness information provided for the UF formulary recommendation. Both the CMA and CEA revealed that

captopril was the most cost-effective ACEI and for this reason should be maintained on the BCF. The CEA showed that lisinopril is a very cost-effective agent, and it currently has a 68% market share at the MTFs.

Additionally, there was discussion regarding addition of an ACEI in combination with HCTZ to the BCF. There currently is no designated BCF ACEI/HCTZ combination, and it was noted that some facilities have seen a shift toward an angiotensin receptor blocker (ARB)/HCTZ combination. Addition of lisinopril in combination with HCTZ is lower in cost than other ACEIs combined with HCTZ, and may offer a convenience benefit to patients.

Conclusion: The P&T Committee concurred with the recommendation to place lisinopril, lisinopril in combination with HCTZ, and captopril on the BCF.

COMMITTEE ACTION: The P&T Committee voted (15 for, 0 opposed, 1 abstained, 1 absent) to recommend lisinopril, lisinopril in combination with HCTZ, and captopril as the BCF agents.

9. CALCIUM CHANNEL BLOCKER (CCB) DRUG CLASS REVIEW

A. CCB UF Relative Clinical Effectiveness: The Committee evaluated the relative clinical effectiveness of the nine CCBs marketed in the U.S.: the dihydropyridines (DHPs) nifedipine (Procardia, Adalat CC, and various generics), nicardipine (Cardene and Cardene SR), isradipine (DynaCirc and DynaCirc SR), felodipine (Plendil and various generics), amlodipine (Norvasc), nisoldipine (Sular), and nimodipine (Nimotop); and the non-dihydropyridines diltiazem (Cardizem, Cardizem SR, Cardizem CD, Cardizem LA, Tiazac, and various generics) and verapamil (Verelan, Verelan PM, Covera HS, Calan, Calan SR, and various generics). (See Table 3, Appendix C for a full listing of the CCBs that were evaluated.) Information regarding the safety, effectiveness, and clinical outcomes of the CCBs when used for cardiovascular conditions was considered. (Nimodipine is used for subarachnoid hemorrhage, but not for cardiovascular conditions; thus, it will not be discussed further in the clinical review.) The clinical review included, but was not limited to the requirements stated in the UF Rule, 32 CFR 199.21.

1) *Efficacy for Hypertension:*

Place in Therapy: The Joint National Commission VII guidelines for treating hypertension state that CCBs are not first-line antihypertensive agents. CCBs are appropriate as add-on therapy with other antihypertensive agents, or in patients with compelling indications (coronary artery disease or DM).

Efficacy of CCB vs CCB: Head-to-head trials show that all are effective at lowering blood pressure, when titrated to effect. There are no head-to-head trials of the CCBs that assess clinical outcomes, such as mortality, stroke, MI, or development of end-stage renal disease.

Efficacy of CCB vs Other Antihypertensive Agents: Sixteen large trials assessing clinical outcomes (mortality, stroke, MI, development of end-stage renal disease) have been conducted with all the CCBs, except felodipine versus other anti-hypertensive agents, including diuretics, beta blockers, ACEIs, and ARBs. The overall quality of the evidence is poor. These 16 trials reported that the CCBs were similar, but not better than the comparator drugs in reducing all-cause mortality. There were no differences between the CCBs. A meta-analysis has not been performed due to the heterogeneity of the trials, presence of patient co-morbidities, and differing clinical endpoints. Two new trials conducted with amlodipine (ASCOT and CAMELOT) do not change the efficacy assessment. Two trials evaluating felodipine with other anti-hypertensive agents did not

have proper randomization (the STOP-2 trial), or did not evaluate felodipine as monotherapy (HOT trial).

Conclusion: The DoD P&T Committee concluded that, for lowering blood pressure, there is no evidence that any one CCB is more effective relative to another. There is insufficient evidence to conclude that any one CCB (amlodipine, diltiazem, isradipine, nicardipine, nifedipine, nisoldipine, or verapamil) is superior to another for reducing risk of cardiovascular outcomes in patients with hypertension. There is no evidence for felodipine when used as a monotherapy for reducing cardiovascular outcomes in patients with hypertension.

2) *Efficacy for Chronic Stable Angina*:

Place in Therapy: The ACC/AHA guidelines for treating chronic stable angina state that improved mortality has been shown with aspirin, lipid management, and beta blockers. CCBs help with improving symptoms, and are reserved for use in patients where a beta blocker is contraindicated, where beta blocker monotherapy is not successful, or in patients with unacceptable adverse effects to beta blockers.

Efficacy of CCB vs CCB for Chronic Stable Angina: There are five head-to-head trials enrolling fewer than 300 patients that have compared a CCB vs CCB, and evaluated symptom improvement (number of angina episodes/week, exercise duration, number of doses of sublingual nitroglycerin). For these five trials, there was no difference in symptom improvement with amlodipine, immediate release diltiazem, sustained release diltiazem, nisoldipine, nicardipine, or nifedipine. There have been no studies with felodipine or isradipine.

Efficacy of CCBs vs Beta Blockers for Chronic Stable Angina: Based on thirteen head-to-head trials comparing CCBs and beta blockers, diltiazem, amlodipine, nicardipine, sustained release nifedipine, nisoldipine, and verapamil all appeared to be similarly efficacious in treating angina symptoms.

Conclusion: The Committee agreed that there is no evidence to conclude that there is any difference in efficacy of amlodipine, nifedipine, diltiazem, nisoldipine, nicardipine, or verapamil in improving angina symptoms. There is no evidence for felodipine or isradipine in head-to-head trials with other CCBs.

3) *Efficacy in Systolic Dysfunction:*

Place in Therapy: The ACC/AHA guidelines for chronic heart failure do not recommend use of a CCB. However, CCBs are used in patients with systolic dysfunction to treat an underlying co-morbidity (hypertension, angina), without adversely compromising the patient's heart failure status.

Efficacy for Systolic Dysfunction: Amlodipine and felodipine have both been shown in one trial each to have no significant effect (neither positive nor negative) on all-cause mortality, or combined fatal and non-fatal events in patients with heart failure. In the V-HeFT III trial, there was no difference between placebo and felodipine in all-cause mortality in 450 patients with primarily New York Heart Association (NYHA) Class II heart failure symptoms. In the PRAISE trial, there was a 9% reduction in the relative risk of the composite outcome of all-cause mortality and cardiovascular morbidity with amlodipine, which was not significantly different from placebo, in 1,153 patients with primarily NYHA class III heart failure.

Conclusion: Based on the clinical evidence, the Committee agreed that when used in patients with heart failure, amlodipine or felodipine do not adversely affect outcomes.

4) *Safety and Tolerability:* In general, the safety profile of an individual CCB reflects its pharmacologic class. The DHPs are peripheral vasodilators, and commonly cause edema, headache, flushing, reflux tachycardia, and dizziness (especially short-acting nifedipine). Verapamil has negative inotropic effects, while diltiazem does not exhibit negative inotropy.

   There are no head–to-head trials of CCB vs CCB that assess clinical outcomes and adverse events. Individual trials in hypertension comparing the CCBs vs other anti-hypertensive agents that evaluated cardiovascular outcomes were insufficient to determine differences in the incidence of withdrawals due to adverse effects for amlodipine, diltiazem, nicardipine, nifedipine, and nisoldipine. For the trials evaluating CCBs in angina, there were no differences in withdrawal rates or adverse events with amlodipine, diltiazem, nicardipine, nifedipine, and nisoldipine. Two long-term observational studies reported that severe adverse events were highest with diltiazem, followed by verapamil, amlodipine, nifedipine, and nicardipine. Although there may be individual patient differences in the incidence of edema, the overall incidence of edema for all the CCBs ranges between 8-10%, and the rates of withdrawal due to edema are similar between CCBs.

   Conclusion: The DoD P&T Committee agreed that there is insufficient evidence to clearly differentiate the CCBs on the basis of adverse events. The most common adverse events are dizziness, peripheral edema, headache, and flushing.

5) *Other Factors:*

   Special Populations: Amlodipine is the only DHP CCB indicated for pediatric use in patients aged 6-16 years with hypertension. Diltiazem and verapamil are used in the pediatric population.

   Dosing Intervals: An evaluation of DHP dosing intervals in DoD showed that 10% of patients receiving sustained release nifedipine required more than 1 dose daily, vs 7% of amlodipine patients.

   Formulations: The CCBs are available in a variety of immediate, sustained, and extended release preparations. Generic preparations are available for several of the products, but the products may not be bioequivalent due to differing release mechanisms. However, the products can be considered therapeutically equivalent, if they contain the same active ingredient. Immediate release nifedipine is no longer used for cardiovascular conditions due to a high incidence of reflux tachycardia and associated increased mortality. There are only 2,100 unique utilizers of immediate release nifedipine (for conditions other than cardiovascular disease) in DoD. This product will not be discussed further in the clinical review.

   Chronotherapeutics: A higher incidence of cardiovascular events (stroke, MI) has been noted in the early morning hours (between 6 AM and 10 AM). The concept of chronotherapeutics theorizes that administering an anti-hypertensive agent in the evening will result in a lowered incidence of next morning cardiovascular events. The verapamil products, Verelan PM and Covera HS, and the diltiazem product, Cardizem LA, are specifically labeled for administration at bedtime. While intriguing, the concept of chronotherapeutics has not been prospectively shown to improve outcomes.

Conclusion: The Committee agreed that there are differences amongst the CCBs in terms of other factors as discussed above.

Clinical Effectiveness Conclusion: The Committee concluded that (1) all eight CCBs have similar relative clinical effectiveness for treating hypertension; (2) there is insufficient evidence to conclude that verapamil, diltiazem, nifedipine, amlodipine, nisoldipine, nicardipine, or isradipine is superior to another for reducing risk of cardiovascular outcomes in patients with hypertension, and that there is no evidence for felodipine; (3) there is no evidence of a difference in improving symptoms of angina with amlodipine, nifedipine, diltiazem, nisoldipine, nicardipine, or verapamil, and that there is no evidence for felodipine or isradipine; (4) amlodipine and felodipine do not adversely or positively affect mortality or morbidity in patients with systolic dysfunction; (5) there is insufficient evidence to clearly differentiate the CCBs on the basis of adverse events, and that the overall incidence of edema ranges between 8-10%, and (6) none of the CCBs should be designated as non-formulary on the UF based solely on the clinical evidence.

COMMITTEE ACTION: The Committee voted (16 for, 0 opposed, 0 abstained, 1 absent) to accept the clinical effectiveness conclusions as stated above.

B. CCB UF Relative Cost Effectiveness:

1) DHP CCBs

a) DHP CCB UF Relative Cost Effectiveness: The P&T Committee evaluated the relative cost-effectiveness of DHP CCBs in relation to safety, tolerability, effectiveness, and clinical outcomes of the other agents in the class. Information considered by the P&T Committee included but, was not limited to, sources of information listed in 32 CFR 199.21(e)(2). From the preceding relative clinical effectiveness evaluation, the P&T Committee considered the clinical merits of the DHP CCBs with regard to:

- Clinical effectiveness in the treatment of hypertension and angina
- Clinical evidence for relative safety and tolerability
- Clinical outcome evidence supporting their effectiveness in heart failure
- Place in therapy (i.e., when do national guidelines recommend the use of these agents)

To determine the relative cost-effectiveness of the agents within the DHP calcium channel blocker therapeutic class, two separate economic analyses were performed: a CMA, and a BIA.

The cost used in the CMA was the total weighted average cost per day of treatment (for all three points of service). The results of the CMA revealed three distinct clusters along the cost-continuum: low, moderate, and high cost agents. The low cost cluster included nifedipine immediate release, nifedipine extended release, and felodipine, whereas the moderate cost cluster included amlodipine, nicardipine immediate release, and nisoldipine. Isradipine immediate release, isradipine controlled release, and nicardipine sustained release were included in the high cost cluster. Based on this use of cost-minimization to determine the relative cost-effectiveness of the agents within DHP calcium channel blocker therapeutic class, nifedipine immediate release, nifedipine extended release, and felodipine were the most cost-effective agents.

The results of the CMA were subsequently incorporated into a BIA. A BIA accounts for other factors and costs associated with a potential decision to recommend that the status of one or more DHP CCBs be classified as non-formulary under the UF, such as market share migration, cost reduction associated with non-formulary cost shares, and medical necessity processing fees. The goal of the BIA was to identify a group of DHP CCBs to be included on the UF which best met the majority of the clinical needs of the DoD population at the lowest cost to the MHS. The BIA results revealed that a group of DHP CCBs that included nifedipine immediate release, nifedipine extended release, felodipine, and nisoldipine best achieved this goal, when compared to other combination groups of DHP CCBs, and thus were determined to be more cost-effective relative to other combination groups.

Conclusion: The P&T Committee, based upon its collective professional judgment, voted (17 for, 0 opposed, 0 abstained, 0 absent) to accept the DHP CCB cost-analysis presented by the PEC. The analysis concluded that isradipine immediate release, isradipine controlled release, nicardipine immediate release, nicardipine sustained release, and amlodipine were not cost-effective relative to the other DHP CCBs. Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of the DHP CCBs, and other relevant factors, the P&T Committee recommended that isradipine immediate release, isradipine controlled release, nicardipine immediate release, nicardipine sustained release, and amlodipine be classified as non-formulary under the UF, with nifedipine immediate release, nifedipine extended release, felodpine, nimodipine, and nisoldipine classified as formulary on the UF.

COMMITTEE ACTION: The P&T Committee, based upon its collective professional judgment, voted (17 for, 0 opposed, 0 abstained, 0 absent) to recommend that that isradipine immediate release, isradipine controlled release, nicardipine immediate release, nicardipine sustained release, and amlodipine be classified as non-formulary under the UF, with nifedipine immediate release, nifedipine extended release, felodpine, nimodipine and nisoldipine classified as formulary on the UF. Nifedipine immediate release and nimodipine are not therapeutic alternatives to the other CCBs, as they are not used for cardiovascular conditions.

b) DHP CCBs BCF Review and Recommendations: The P&T Committee reviewed the DHP CCBs recommended for inclusion on the UF to select the BCF DHP CCBs. It had previously been decided that one DHP calcium channel blocker could be added to the BCF, based on the outcome of relative clinical effectiveness and relative cost effectiveness determinations.

Currently the only DHP calcium channel blocker on the BCF is nifedipine extended release (Adalat CC or equivalent). From a clinical and cost-effective standpoint, this remains a rational selection for the BCF. MTFs continue to enjoy a good price for this agent, and the VA is expected to complete a sole-source generic contract for a nifedipine extended release product in the next few months. BCF prices were submitted for amlodipine and nisoldipine. However, the BIA revealed that neither was competitive, and that nifedipine CC was the most cost-effective DHP calcium channel blocker, and for this reason should be maintained on the BCF. MTFs can add additional DHP CCBs from the UF to their local formularies if needed to meet the needs of their specific patient populations.

Conclusion: The P&T Committee concurred with the recommendation to place nifedipine extended release on the BCF. As the CC formulation is currently the most cost-effective choice, the BCF listing will state that MTFs are required to carry the CC formulation of nifedipine extended release, until a new DoD/VA sole source contract for nifedipine extended release is completed.

COMMITTEE ACTION: The P&T Committee voted (17 for, 0 opposed, 0 abstained, 0 absent) to recommend nifedipine extended release as the BCF agent.

2) Verapamil

a) Verapamil UF Relative Cost Effectiveness: The P&T Committee evaluated the relative cost-effectiveness of verapamil agents in relation to safety, tolerability, effectiveness, and clinical outcomes of the other agents in the class. Information considered by the P&T Committee included, but was not limited to, sources of information listed in 32 CFR 199.21(e)(2). To determine the relative cost-effectiveness of the verapamil agents, two separate economic analyses were performed: a pharmacoeconomic analysis and a BIA. From the preceding relative clinical effectiveness evaluation, the P&T Committee determined that verapamil agents have similar relative clinical effectiveness in the treatment of hypertension and angina, have similar safety and tolerability, but differ in their indications for night-time dosing. However, the Committee agreed that the night-time dosing indication was of minimal clinical importance as there was no literature evidence that night-time dosing has a positive benefit on clinical outcomes. Therefore, a CMA was performed to stratify the agents solely on cost. The cost used in the analysis was the total weighted average cost per day of treatment (for all three points of service).

The results of the CMA revealed three distinct clusters along the cost-continuum: low, moderate, and high cost agents. The low cost cluster included verapamil immediate release and verapamil sustained release, whereas the moderate cost cluster included the Verelan brand of verapamil extended release capsules. Verelan PM and Covera HS, two long-acting, night-time dosed verapamil brands, represented the high cost cluster. Within the verapamil CCB therapeutic subclass, verapamil immediate release and verapamil sustained release were the most cost-effective agents. The results of the CMA and CEA were subsequently incorporated into a BIA. A BIA accounts for other factors and costs associated with a potential decision to recommend that the status of one or more verapamil CCBs be changed from formulary to non-formulary such as market share migration, cost reduction associated with non-formulary cost shares, and medical necessity processing fees. The goal of the BIA was to identify a group of verapamil agents to be included on the UF, which best met the majority of the clinical needs of the DoD population at the lowest cost to the MHS. The BIA results revealed that a group of verapamil agents that included verapamil immediate release and verapamil sustained release best achieved this goal when compared to other combination groups of verapamil agents, and thus were determined to be more cost-effective relative to other combination groups.

Conclusion: The P&T Committee, based upon its collective professional judgment, voted (17 for, 0 opposed, 0 abstained, 0 absent) to accept the verapamil CCB cost-analysis presented by the PEC. The P&T Committee concluded that Verelan, Verelan PM, and Covera HS were not cost-effective relative to the other verapamil agents, as they were more costly and provided no additional clinically meaningful benefit over the most cost-effective agents. Taking into consideration the conclusions

from the relative clinical effectiveness and relative cost effectiveness determinations of the verapamil agents, and other relevant factors, the P&T Committee recommended that Verelan, Verelan PM and Covera HS be classified as non-formulary under the UF, and verapamil immediate release and verapamil sustained release be classified as formulary on the UF.

COMMITTEE ACTION: The P&T Committee, based upon its collective professional judgment, voted (17 for, 0 opposed, 0 abstained, 0 absent) to recommend formulary status for verapamil immediate release and verapamil sustained release, and non-formulary status for Verelan, Verelan PM and Covera HS on the UF.

b) Verapamil BCF Review and Recommendations: The P&T Committee reviewed the verapamil agents recommended for inclusion on the UF to select the BCF verapamil agent. It had previously been decided that one verapamil agent would be added to the BCF, based on the outcome of relative clinical effectiveness and relative cost effectiveness determinations.

Verapamil sustained release is currently on the BCF. From a clinical and economic standpoint, this remains a rational selection for the BCF. MTFs continue to enjoy a good price for this agent, which represents the majority of verapamil use in the MHS. Verapamil sustained release is currently the most cost-effective long acting verapamil agent. For this reason, it should be maintained on the BCF. MTFs may add verapamil immediate release to their local formularies if needed to meet the needs of their specific patient populations.

Conclusion: The P&T Committee concluded that verapamil sustained release should remain on the BCF.

COMMITTEE ACTION: The P&T Committee voted (17 for, 0 opposed, 0 abstained, 0 absent) to recommend retaining verapamil sustained release as the BCF agent.

3) Diltiazem

a) Diltiazem UF Relative Cost Effectiveness: The P&T Committee evaluated the relative cost-effectiveness of diltiazem agents in relation to safety, tolerability, effectiveness, and clinical outcomes to the other agents in the class. Information considered by the P&T Committee included, but was not limited to, sources of information listed in 32 CFR 199.21(e)(2). To determine the relative cost-effectiveness of diltiazem agents, two separate economic analyses were performed: a pharmacoeconomic analysis and a BIA. From the preceding relative clinical effectiveness evaluation, the P&T Committee determined that diltiazem agents have similar relative clinical effectiveness in the treatment of hypertension and angina, and similar safety and tolerability, but differ in their indications for night-time dosing. However, the Committee agreed that the night-time dosing indication was of minimal clinical importance as there was no literature evidence that night-time dosing has a positive benefit on clinical outcomes. Therefore, a CMA was performed to stratify the agents solely on cost. The cost used in the analysis was the total weighted average cost per day of treatment (for all three points of service).

The results of the CMA revealed three distinct clusters along the cost-continuum: low, moderate, and high cost agents. The low cost cluster included diltiazem immediate release, whereas the moderate cost cluster included diltiazem extended release and diltiazem sustained release. Cardizem LA represented the high cost cluster. The CMA

showed that diltiazem immediate release, diltiazem extended release, and diltiazem sustained release were the most cost-effective agents. The results of the CMA were subsequently incorporated into a BIA. A BIA accounts for other factors and costs associated with non-formulary decisions, such as market share migration, cost reduction associated with non-formulary cost shares, and medical necessity processing fees. The goal of the BIA was to identify a group of diltiazem agents to be included on the UF which best met the majority of the clinical needs of the DoD population at the lowest cost to the MHS. The BIA showed that the most cost-effective combination of diltiazem agents was diltiazem immediate release, diltiazem extended release, and diltiazem sustained releae.

Conclusion: The P&T Committee, based upon its collective professional judgment, voted (17 for, 0 opposed, 0 abstained, 0 absent) to accept the diltiazem cost-analysis presented by the PEC. The analysis concluded that Cardizem LA was not cost-effective relative to the other diltiazem agents, since it was more costly and provided no additional clinically-meaningful benefit over the most cost-effective agents. Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of the diltiazem agents, and other relevant factors, the P&T Committee recommended that Cardizem LA be classified as non-formulary under the UF Formulary, and diltiazem immediate release, diltiazem sustained release, and diltiazem extended release be classified as formulary on the UF.

COMMITTEE ACTION: The P&T Committee, based upon its collective professional judgment, voted (17 for, 0 opposed, 0 abstained, 0 absent) to recommend formulary status for diltiazem immediate release, diltiazem sustained release, and diltiazem extended release, and non-formulary status for Cardizem LA under the UF.

b) Diltiazem BCF Review and Recommendations: The P&T Committee reviewed the diltiazem agents recommended for inclusion on the UF to select the BCF diltiazem agent. It had previously been decided that one diltiazem agent would be added to the BCF, based on the outcome of relative clinical effectiveness and relative cost effectiveness determinations.

Diltiazem extended release is currently on the BCF. From a clinical and economic standpoint, this remains a rational selection for the BCF. The MTFs continue to enjoy a good price for this agent, and 97% of usage in the DoD MHS is for the diltiazem extended release product. The Tiazac brand of diltiazem extended release is currently the most cost-effective diltiazem extended release agent and should be selected for the BCF. MTFs may add additional diltiazem agents from the UF to their local formularies, if needed to meet the needs of their specific patient populations.

Conclusion: The P&T Committee concurred with the recommendation to place diltiazem extended release on the BCF. As the Tiazac formulation is currently the most cost-effective choice, the BCF listing will state that MTFs are required to carry the Tiazac formulation of extended release diltiazem.

COMMITTEE ACTION: The P&T Committee voted (17 for, 0 opposed, 0 abstained, 0 absent) to recommend diltiazem extended release as the BCF agent.

C. CCB UF Medical Necessity Criteria: Based on the clinical evaluation of the CCBs and the conditions for establishing medical necessity for a non-formulary medication provided for in

the UF rule, the P&T Committee concluded that the following general medical necessity criteria would apply for these agents:

1) Use of the formulary CCBs (nifedipine immediate release, nifedipine extended release, felodipine, nimodipine, nisoldipine, verapamil immediate release, verapamil sustained release, diltiazem immediate release, diltiazem sustained release and diltiazem extended release is contraindicated, and the use of non-formulary CCBs (isradipine immediate release, isradipine controlled release, nicardipine immediate release, nicardipine sustained release, amlodipine, Verelan, Verelan PM, Covera HS, and Cardizem LA) is not contraindicated.

2) The patient has experienced or is likely to experience significant adverse effects from the formulary CCBs, and the patient is reasonably expected to tolerate a non-formulary CCB.

3) Use of the formulary CCBs resulted in therapeutic failure, and the patient is reasonably expected to respond to a non-formulary CCB [therapeutic failure as outlined on medical necessity form].

4) The patient has previously responded to a non-formulary CCB, and changing to a formulary CCB would incur unacceptable risk.

5) There is no alternative pharmaceutical agent on the formulary.

The Committee noted that criteria 4 and 5 would reasonably apply only to a small subset of patients receiving CCBs, such as patients with NYHA Class III or IV heart failure similar to those in the V-HeFT and PRAISE trials or clinically fragile patients with angina and multiple comorbidities who are stable on amlodipine. The Committee also noted that amlodipine is the only long-acting DHP CCB approved by the FDA for pediatric patients. The Committee recommended that medical necessity be automatically approved for patients younger than 18 years of age, if this is technically feasible (i.e., if the Pharmacy Data Transaction Service can be programmed to permit scripts for beneficiaries age <18 years to be filled without medical necessity being established).

COMMITTEE ACTION: The P&T Committee voted (17 for, 0 opposed, 0 abstained, 0 absent) to approve the medical necessity criteria.

D. CCB UF Implementation Plan: Because a substantial number of patients (268,000, or 73% of all patients receiving CCBs) are currently receiving CCBs recommended for non-formulary status, the P&T Committee recommended an effective date no later than the first Wednesday following a 150-day implementation period. The implementation period will begin immediately following the approval by the Director, TMA

COMMITTEE ACTION: The Committee voted (16 for, 0 opposed, 0 abstained, 1 absent) to recommend an implementation period of 150 days.

10. ALPHA BLOCKERS FOR BENIGN PROSTATIC HYPERTROPHY (BPH) DRUG CLASS REVIEW

A. Alpha Blocker UF Clinical Effectiveness: The P&T Committee evaluated the relative clinical effectiveness of alpha blockers FDA-approved for BPH: terazosin (Hytrin and various generics), doxazosin (Cardura and various generics), alfuzosin (Uroxatral) and tamsulosin (Flomax). First-generation (phenoxybenzamine) alpha-adrenergic antagonists have been replaced by second generation (terazosin, doxazosin) and third-generation (tamsulosin, alfuzosin) alpha blockers. The clinical review included consideration of pertinent information

from a variety of sources determined by the P&T Committee to be relevant and reliable, including, but not limited to, sources of information listed in 32 CFR 199.21(e)(1). The P&T Committee was advised that there is a statutory presumption that pharmaceutical agents in a therapeutic class are clinically effective and should be included on the UF unless the P&T Committee finds by a majority vote that a pharmaceutical agent does not have a significant, clinically meaningful therapeutic advantage in terms of safety, effectiveness, or clinical outcome over the other pharmaceutical agents included on the UF in that therapeutic class.

The P&T Committee agreed that in the MHS, alpha blockers are considered a gold standard for treating symptoms of BPH. During a twelve-month period ending 30 April 2005, approximately 196,388 patients were prescribed an alpha blocker. This class is now ranked 25th in MHS drug class expenditures.

Efficacy: All alpha blockers are FDA-approved for the treatment of BPH. There are limited head-to-head trials comparing the four alpha blockers. The available placebo controlled trials, and meta-analyses were reviewed. Although all alpha blockers were found to be clinically effective when compared to placebo, variability in study design, demographics, and outcome measures precluded the ability to designate one alpha blocker as clinically superior. The Cochrane Database, Clinical Evidence, and the American Urological Association (evidence-based healthcare systematic reviews) concurred that all four alpha blockers are clinically interchangeable in regards to efficacy. In the tools used to measure effectiveness, all four drugs relieve BPH symptoms, improve standardized testing symptom scores, and improve urinary flow rates to the same extent. The alpha blockers appear to be similar in terms of clinical efficacy.

Safety/Tolerability: The P&T Committee found that the alpha blockers had similar safety data within their generation with respect to drug interactions, and adverse drug reactions. Adverse effects are primarily related to the agent's target receptor subtype (terazosin and doxazosin are nonselective; alfuzosin and tamsulosin are selective). As of August 2005, all agents have similar alpha-blocker postural hypotension warnings. Nonselective alpha blockers exhibit a higher rate of vasodilatory adverse effects (dizziness, asthenia, postural hypotension) relative to selective alpha blockers. Alfuzosin and tamsulosin appear to be better tolerated than terazosin and doxazosin as measured by withdrawals due to adverse events and discontinuation of therapy.

Conclusion: The P&T Committee concluded that there is no compelling evidence to support clear superiority of one agent over another in terms of efficacy. All alpha blockers have been shown to have a positive effect on the symptoms of BPH. Selective alpha blockers appear to have a lower rate of adverse vasodilatory effects, a safety/tolerability advantage.

COMMITTEE ACTION: The P&T Committee voted (16 for, 0 opposed, 0 abstained, 1 absent) that for the purposes of the UF clinical review, all alpha blockers have similar efficacy for treating BPH. All alpha blockers have similar safety and tolerability profiles within alpha blocker generations.

B. Alpha Blocker Relative Cost Effectiveness: The P&T Committee evaluated the relative cost-effectiveness of the agents within the alpha blocker class in relation to safety, tolerability, effectiveness, and clinical outcomes of the other agents in the class. Information considered by the P&T Committee included but was not limited to sources of information listed in 32 CFR 199.21(e)(2).

To determine the relative cost-effectiveness of the agents within the alpha blocker therapeutic class, two separate economic analyses were performed, a pharmacoeconomic analysis and a BIA. From the preceding relative clinical effectiveness evaluation, the P&T Committee determined that alpha blockers have similar relative clinical effectiveness in the treatment of lower urinary tract symptoms often associated with BPH, but differ in safety and tolerability, especially in comparison to non-selective alpha blockers with selective alpha blockers. The agents within the alpha blocker therapeutic class were thus shown to differ in relative clinical effectiveness.

First, a CMA was performed to stratify the agents on cost. The results of the CMA revealed that non-selective alpha blockers were more cost-effective compared to non-selective alpha blockers, by nearly ten-fold based on the total weighted average cost per day of treatment (for all three points of service). Within the non-selective alpha blocker sub-class, doxazosin was found to be slightly more cost-effective compared to terazosin and within the selective alpha blocker sub-class alfuzosin was found to be considerably more cost-effective compared to tamsulosin (alfuzosin cost per day of treatment was 20% lower than tamsulosin's cost per day of treatment).

Given this conclusion, a CEA was employed, which accounted for differences in safety and tolerability between the non-selective alpha blocker sub-class and the selective alpha blocker sub-class. In this type of analysis, agents within a therapeutic class are competed on two dimensions, cost and effect (outcomes). For this particular CEA, a Markov model was constructed based upon the outcomes reported in the Medical Therapy of Prostatic Symptoms Study (MTOPS) for the doxazosin arm. The drug cost used in the analysis was the total weighted average cost per day of treatment (for all three points of service). Direct medical costs associated with disease clinical progression and treatment of adverse drug events were also incorporated into the model.

Two CEAs were performed. In the first analysis, the effect (outcome) was defined as successfully treated patients. In the second analysis, the effect was defined as successfully treated patients without adverse drug events, more specifically, cardiovascular/ hypotensive adverse drug events associated with non-selective alpha blockers. The overall results from the first CEA paralleled the results obtained in the CMA: non-selective alpha blockers and selective alpha blockers were equally effective, non-selective alpha blockers were more cost-effective compared to selective alpha blockers, doxazosin was slightly more cost-effective compared to terazosin, and alfuzosin was considerably more cost-effective compared to tamsulosin. However, when the cost of adverse events associated with non-selective alpha blocker treatment was considered, the difference in cost per successfully treated patient between the non-selective and selective alpha blockers was two-fold, not ten-fold (as shown in the CMA). The results from the second CEA revealed selective alpha blockers were more effective (more patients successfully treated without adverse drug events), but more costly compared to non-selective alpha blockers. Although there was still approximately a two-fold difference in cost of treatment between the non-selective and selective alpha blockers, the incremental cost was less compared to the first CEA.

The results of the CMA and CEA were subsequently incorporated into a BIA. A BIA accounts for other factors and costs associated with a potential decision to recommend that one or more alpha blockers be classified as non-formulary, such as market share migration, cost reduction associated with non-formulary cost shares, and medical necessity processing fees. The goal of the BIA was to identify a group of alpha blockers to be included on the UF which best met the

majority of the clinical needs of the DoD population at the lowest cost to the MHS. The BIA results revealed that a group of alpha blockers that included alfuzosin, doxazosin, and terazosin best achieved this goal when compared to other combination groups of alpha blockers, and thus were determined to be more cost-effective relative to other combination groups.

*Conclusion**:*** The P&T Committee, based upon its collective professional judgment, voted (16 for, 0 opposed, 0 abstained, 1 absent) to accept the BPH alpha-blocker cost-analysis presented by the PEC. The P&T Committee concluded that doxazosin and terazosin had similar relative cost-effectiveness in the non-selective alpha blocker subclass, but determined that tamsulosin was not cost-effective relative to alfuzosin in the selective alpha blocker sub-class. Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations, and other relevant factors, the P&T Committee recommended that tamsulosin be classified as non-formulary under the UF, and that doxazosin, terazosin, and alfuzosin be classified as formulary on the UF.

COMMITTEE ACTION: The P&T Committee, based upon its collective professional judgment, voted (16 for, 0 opposed, 0 abstained, 1 absent) to recommend formulary status for doxazosin, terazosin, and alfuzosin, and non-formulary status for tamsulosin under the UF.

C. Alpha Blocker UF Medical Necessity Criteria: Based on the clinical evaluation of the alpha blockers and the conditions for establishing medical necessity for a non-formulary medication provided for in the UF rule, the P&T Committee concluded that the following general medical necessity criteria would apply for these agents:

1) Use of a formulary alpha blocker (terazosin, doxazosin, alfuzosin) is contraindicated, and the use of a nonformulary alpha blocker (tamsulosin) is not contraindicated.

2) The patient has experienced or is likely to experience significant adverse effects from a formulary alpha blocker, and the patient is reasonably expected to tolerate a non-formulary alpha blocker.

3) Use of the formulary alpha blocker resulted in therapeutic failure, and the patient is reasonably expected to respond to a non-formulary alpha blocker [therapeutic failure as outlined on medical necessity form].

Because the UF would include both selective and nonselective agents, the Committee agreed that the situations covered by general criterion 4 (changing to a formulary agent would incur unacceptable risk) and general criterion 5 (no alternative pharmaceutical agent on the formulary) would not apply in this category. The Committee also noted it would be reasonable for a patient who experienced adverse effects (e.g., dizziness, postural hypotension) on terazosin or doxazosin, and who could not be treated with alfuzosin, to meet medical necessity requirements for tamsulosin without requiring that the patient fail or be unable to take both formulary non-selective agents.

D. Alpha Blocker UF Implementation Plan: Because a number of patients are currently receiving tamsulosin from one of the three MHS pharmacy points of service (89,926 patients, 46% of all patients receiving alpha blockers), the P&T Committee proposed a 120-day transition period for implementation of the decision to classify tamsulosin as non-formulary under the UF.

COMMITTEE ACTION: The P&T Committee recommended (16 for, 0 opposed, 0 abstained, 0 absent) an effective date no later than the first Wednesday following a 120-day

implementation period. The implementation period will begin immediately following the approval by the Director, TMA.

E. Alpha-Blocker Basic Core Formulary (BCF) Review and Recommendations: The P&T Committee reviewed the alpha blockers recommended for inclusion on the UF to select the BCF alpha blockers. It had previously been decided that at least one, but no more than two alpha blockers, would be added to the BCF, based on the outcome of relative clinical effectiveness and relative cost effectiveness determinations.

Terazosin is currently the only alpha blocker on the BCF, has a current MTF market share of 63%, and, when properly titrated, is safe and effective in the majority of patients requiring treatment for BPH. Although marginally less costly, doxazosin has a much lower MTF market share and offers no clinical advantage compared to terazosin.

There are three arguments supporting placement of alfuzosin on the BCF:

1) Provides increased access to a selective alpha blocker for MTF patients who cannot tolerate a non-selective alpha blocker, or in whom a non-selective alpha blocker is contraindicated due to co-morbid conditions
2) The CEA suggests the difference in the cost of treatment between selective alpha blocker and non-selective alpha blocker is not ten-fold (total weighed average cost per day of treatment at all three points of service), but closer to two-fold when the costs of non-selective alpha blocker adverse drug events are considered.
3) Based on the total weighted average cost per day of treatment for MTFs, alfuzosin is 43% less costly than tamsulosin.

The primary disadvantage of adding a selective alpha blocker to the BCF is that it would require those MTFs who currently do not have a selective alpha blocker on their formulary to add alfuzosin, and thus increase MTF pharmacy expenditures. However, utilization of selective alpha blockers is increasing at MTFs, and adding alfuzosin now would reduce the unit cost for a selective alpha blocker.

Conclusion: The P&T Committee recommended placing alfuzosin and terazosin on the BCF.

COMMITTEE ACTION: The P&T Committee voted (16 for, 0 opposed, 0 abstained, 1 absent) to recommend alfuzosin and terazosin as the BCF agents.

11. ANTIDEPRESSANTS (EXCLUDING MONOAMINE OXIDASE INHIBITORS AND TRICYCLIC ANTIDEPRESSANTS)

PEC staff presented a clinical review of the antidepressant medications listed below to the Committee. Although the receptor-binding characteristics and pharmacological classification of these medications vary, the Committee agreed that there is sufficient overlap in their clinical use to review them as a single class of medications.

- *Selective Serotonin Reuptake Inhibitors (SSRIs)* - citalopram, escitalopram (Lexapro), fluoxetine, fluvoxamine, paroxetine, and sertraline (Zoloft)
- *Serotonin Norepinephrine Reuptake Inhibitors (SNRIs)* - venlafaxine (Effexor, Effexor XR), duloxetine (Cymbalta)
- *Norepinephrine Dopamine Reuptake Inhibitors (NDRIs)* - bupropion
- *Alpha-2 antagonists* - mirtazapine
- *Serotonin modulators* – nefazodone, trazodone

Seven of these medications are currently on the BCF: the SSRIs citalopram, fluoxetine (excludes Sarafem, Prozac Weekly), paroxetine (excludes Paxil CR), and sertraline; the SNRI venlafaxine sustained release (Effexor XR); the NDRI bupropion sustained release (excludes Wellbutrin XL); and the serotonin modulator trazodone.

The Committee provided expert opinion regarding the key questions in this drug class and clinical outcomes of importance for the purpose of developing an appropriate cost effectiveness model. Both the clinical and cost effectiveness analyses will be completed during the November 2005 meeting; no action necessary.

12. CHOLINESTERASE AND N-METHYL D-ASPARTATE (NMDA) INHIBITORS FOR ALZHEIMER'S DISEASE

PEC staff presented a clinical review of the cholinesterase and NMDA inhibitors used for the treatment of Alzheimer's disease. The agents in this class include: tacrine (Cognex), donepezil (Aricept), rivastigmine (Exelon), galantamine (Razadyne, formerly Reminyl), and memantine (Namenda). The current BCF agent for this class is donepezil.

The Committee provided expert opinion regarding the key questions in this drug class and clinical outcomes of importance for the purpose of developing an appropriate cost-effectiveness model. Both the clinical and cost-effectiveness analyses will be completed during the November 2005 meeting; no action necessary.

13. ADJOURNMENT

The third day of the meeting adjourned at 1230 hours on August 18, 2005. The dates of the next meeting are November 16–18, 2005.

Appendix A – Table 1: Implementation Status of UF Decisions

Meeting	Drug Class	Non-Formulary Medications	BCF/ ECF	BCF/ECF Medications	Status		
					Decision Date (DoD P&T Minutes signed)	**Effective Date of Non-Formulary Decision**	**BCF/ECF**
May 05	PDE-5 Inhibitors	sildenafil (Viagra) tadalafil (Cialis)	ECF	vardenafil (Levitra)	14 Jul 05	12 Oct 05 (90-day implementation period)	ECF selection effective 14 Jul 05: MTFs may add vardenafil to formulary based on local needs
May 05	Topical Antifungals*	econazole ciclopirox oxiconazole (Oxistat) sertaconazole (Ertaczo) sulconazole (Exelderm)	BCF	nystatin clotrimazole	14 Jul 05	17 Aug 05 (30-day implementation period)	BCF selection effective 14 Jul 05: MTFs must have nystatin and clotrimazole topical products on formulary.
May 05	MS-DMDs	-	ECF	Interferon beta-1a intramuscular injection (Avonex)	14 Jul 05	-	ECF selection effective 14 Jul 05: MTFs must have Avonex on formulary if local needs necessitate having medications in this class on formulary.
Feb 05	ARBs	eprosartan (Teveten) eprosartan/HCTZ (Teveten HCT)	BCF	telmisartan (Micardis) telmisartan/HCTZ (Micardis HCT)	18 Apr 05	17 Jul 05 (90-day implementation period)	BCF selection effective 18 Apr 05: MTFs must have telmisartan and telmisartan/HCTZ on formulary.
Feb 05	PPIs	esomeprazole (Nexium)	BCF	omeprazole rabeprazole (Aciphex)	18 Apr 05	17 Jul 05 (90-day implementation period)	BCF selection effective 18 Apr 05: MTFs must have omeprazole and rabeprazole on formulary.

BCF = Basic Core Formulary; ECF = Extended Core Formulary; ESI = Express-Scripts, Inc; TMOP = TRICARE Mail Order Pharmacy; TRRx = TRICARE Retail Pharmacy program; MN = Medical Necessity; PDE-5 Inhibitors = Phosphodiesterase-5 inhibitors; MS-DMDs = Multiple Sclerosis Disease-Modifying Drugs; ARBs = Angiotensin Receptor Blockers; PPIs = Proton Pump Inhibitors; HCTZ = hydrochlorothiazide

*The topical antifungal drug class excludes vaginal products and products for onychomycosis (e.g., ciclopirox topical solution [Penlac])

Appendix B – Table 2: Newly Approved Drugs

Medication & Mechanism of Action	FDA Approval Date; FDA-Approved Indications	Committee Recommendation
Sildenafil (Revatio; Pfizer)	6 Jun 2005; treatment of pulmonary arterial hypertension (WHO group I) to improve exercise capacity. Efficacy has not been evaluated in patients currently on bosentan therapy. Pulmonary arterial hypertension is also known as primary pulmonary hypertension.	UF Drug Class: PDE-5 Inhibitors Committee Recommendation: Add to the UF Note: Prior authorization (PA) requirements previously established for the PDE-5 inhibitor class apply to Revatio. Since all patients receiving Revatio must meet PA requirements, the Committee did not recommend a specific quantity limit.
Exenatide injection (Byetta; Amylin)	28 Apr 2005; adjunctive therapy to improve glycemic control in patients with type 2 diabetes mellitus who are taking metformin, a sulfonylurea, or a combination of metformin and a sulfonylurea but have not achieved adequate glycemic control.	No UF recommendation at this meeting. Consideration of UF status deferred until drug class is reviewed.
Isosorbide dinitrate / hydralazine tabs (BiDil; Nitromed)	23 Jun 2005; treatment of heart failure as an adjunct to standard therapy in self-identified black patients to improve survival, to prolong time to hospitalization for heart failure, and to improve patient-reported functional status.	No UF recommendation at this meeting. Consideration of UF status deferred until drug class is reviewed.
Bromfenac ophthalmic solution 0.09% (Xibrom; ISTA)	24 Mar 2005; indicated for the treatment of postoperative inflammation in patients who have undergone cataract extraction.	No UF recommendation at this meeting. Consideration of UF status deferred until drug class is reviewed.
Paracalcitol caps (Zemplar; Abbott) Synthetically manufactured analog of calcitriol, the metabolically active form of Vitamin D	26 May 2005; prevention and treatment of secondary hyperparathyroidism associated with chronic kidney disease stage 3 and 4. [The injectable formulation is approved for patients requiring dialysis (stage 5).]	No UF recommendation at this meeting. Consideration of UF status deferred until drug class is reviewed.

Appendix C – Table 3: Calcium Channel Blocker Brand and Generic Names

Generic Name	Brand (Manufacturer)	Generic products available
Dihydropyridines (DHPs)		
Amlodipine	***Norvasc*** (Pfizer)	**No**
Felodipine	Plendil (AstraZeneca)	Yes
Isradipine	***DynaCirc*** [immediate release formulation] (Reliant)	**No**
	DynaCirc CR (Reliant) [Gastrointestinal Therapeutic System (GITS)]	**No**
Nicardipine	Cardene [immediate release formulation] (Roche)	Yes
	Cardene SR (Roche) [granules/powder mix]	**No**
Nifedipine	**Immediate Release***	
	Procardia (Pfizer)	Yes
	Extended Release	
	Adalat CC (Bayer); Afeditab CR (Watson); Nifediac CC (Teva); [core coat]	Yes
	Procardia XL (Pfizer); Nifedical XL (Teva) [GITS]	Yes
Nimodipine	Nimotop*	No
Nisoldipine	***Sular*** (First Horizon) [core coat]	**No**
Non-dihydropyridines (non-DHPs): Verapamil products		
Verapamil	**Immediate Release**	
	Isoptin (FSC); Calan (Searle)	Yes, to Isoptin
	Sustained Release	
	Calan SR; Isoptin SR (Par)	Yes to Isoptin SR
	Extended Release	
	Verelan (Elan)	**No**
	Extended Release for bedtime dosing	
	Verelan PM (Elan)	**No**
	Covera HS (Searle)	**No**
Non-dihydropyridines (non-DHPs): Diltiazem products		
Diltiazem	**Immediate Release**	
	Cardizem (Kos)	Yes
	Sustained Release	
	Diltiazem HCL (Cardizem SR)	Yes
	Extended Release	
	Cardizem CD (Biovail)	Yes, except 360 mg does not have generics
	Dilacor XR (Watson); Diltia XT (Andrx)	Yes
	Cardizem CD; Cartia XT (Andrx)	Yes
	Tiazac (Biovail), Taztia XT (Andrx)	Yes
	Tiazac (Forest, Inwood)	Yes, except 420 mg does not have generics
	Extended Release for bedtime dosing	
	Cardizem LA (Kos)	**No**

***Nifedipine immediate release and nimodipine are not therapeutic alternatives to the other calcium channel blockers, as they are not used for cardiovascular conditions.**

19 May 2005

DECISION PAPER:

MAY 2005 DoD PHARMACY AND THERAPEUTICS COMMITTEE RECOMMENDATIONS

1. CONVENING

2. ATTENDANCE

3. REVIEW MINUTES OF LAST MEETING

4. INTERIM DECISIONS/ADMINISTRATIVE ISSUES

5. ITEMS FOR INFORMATION

6. REVIEW OF RECENTLY APPROVED AGENTS

7. BASIC CORE FORMULARY (BCF) CLARIFICATION OF RECENTLY APPROVED DRUGS

The DoD Pharmacy and Therapeutics (P&T) Committee reviewed the relative clinical and cost effectiveness of the following recently approved formulations of medications already listed on the BCF.

A. Alendronate 70 mg / cholecalciferol (vitamin D) 2800 IU (Fosamax Plus D)

The current BCF listing for alendronate includes all oral strengths except for 40 mg tablets, which are indicated only for the treatment of Paget's disease. Currently, the majority of use across DoD is of the weekly formulations of alendronate (35- and 70-mg tablets). Addition of vitamin D, which is required for normal bone formation, to alendronate may provide a clinical advantage for patients who have inadequate dietary intake of vitamin D and insufficient exposure to sunlight. Taking into account the manufacturer's offer to add alendronate plus D to the current BPA for alendronate without an increase in price, and because the product is not expected to delay the availability of generic versions of alendronate or alendronate plus vitamin D, the Committee agreed that the product offers a small clinical advantage to military treatment facility (MTF) patients at no additional cost. (See paragraph 7 A. on page 13 of P&T Committee minutes.)

COMMITTEE ACTION: The Committee recommended adding alendronate plus D to the BCF (17 for, 1 abstained, 1 absent).

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

B. Fluticasone Propionate HFA (Flovent HCA)

The current BCF listing is for fluticasone oral inhaler. The manufacturer is no longer manufacturing the chlorofluorocarbon (CFC)-containing product (Flovent) and is replacing it with a hydrofluoroalkane (HFA)-containing product (Flovent HFA). Since the product is now the only fluticasone metered dose inhaler available and since the HFA product does not appear to offer any clinical disadvantages compared to the CFC product, the Committee agreed that there was no need to clarify the current BCF listing. As of May 2005, the Flovent HFA metered dose inhaler was available to MTFs and the mail order program at the same price as the old CFC formulation. (See paragraph 7 B. on pages 13-14 of P&T Committee minutes.) No action taken.

C. Insulin Glargine (Lantus) 100 u/mL 3 mL cartridges

The current BCF listing is for insulin glargine injection (Lantus), which was previously available only as a 10 mL vial. The 3 mL cartridges are designed for use with the manufacturer's OptiClik device. The Committee agreed that while this device may benefit some patients (e.g., patients who are needle-phobic or visually impaired), the number of patients who would benefit represents only a small percentage of patients using insulin glargine. The Committee noted that, overall, about 92% of insulin use in DoD is vials, with insulin pens, cartridges, and dispensing syringes representing only 8% of use. The Federal Supply Schedule (FSS) price (as of May 2005) for Lantus was $25.70 for the 10 mL vial ($2.67 per mL) vs. $79.09 for a box of five 3 mL cartridges ($5.27 per mL). The Committee agreed that the potential clinical benefit associated with use of the cartridges was not sufficient to justify the additional cost. (See paragraph 7 C. on page 14 of P&T Committee minutes.)

COMMITTEE ACTION: The Committee recommended clarifying the current BCF listing for insulin glargine injection to exclude the 100 u/mL 3 mL cartridges (18 for, 1 abstained).

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

8. PHOSPHODIESTERASE-5 (PDE-5) INHIBITOR DRUG CLASS REVIEW

The P&T Committee evaluated the relative clinical effectiveness and cost effectiveness of the three PDE-5 inhibitors: sildenafil (Viagra), vardenafil (Levitra); and tadalafil (Cialis). There has been an increase in the use of PDE-5s over the past five years, placing this class in the top 50 of Military Health System (MHS) drug class expenditures.

A. COMMITTEE ACTION: The P&T Committee concluded that none of the PDE-5 inhibitors have a significant clinically meaningful therapeutic advantage in terms of safety, effectiveness, or clinical outcome over the other PDE-5 inhibitors. (See paragraph 8 A. on pages 14-15 of P&T Committee minutes.) The Committee concluded that sildenafil and

tadalafil were not cost effective relative to vardenafil. Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of the PDE-5 inhibitors, the P&T Committee voted (17 for, 0 opposed, 1 abstained, 1 absent) to recommend formulary status for vardenafil and non-formulary status for sildenafil and tadalafil under the Uniform Formulary (UF). (See paragraph 8 B. on pages 15-16 of P&T Committee minutes) Under 32 C.F.R. 199.21(g)(3), no pharmaceutical agent may be designated as non-formulary on the UF unless preceded by such recommendation by the P&T Committee.

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

B. COMMITTEE ACTION: Based on the clinical evaluations of sildenafil and tadalafil, and the conditions for establishing medical necessity for a non-formulary medication provided for in the UF rule, the P&T Committee recommended medical necessity criteria for the sildenafil and tadalafil (18 for, 0 opposed, 0 abstained). (See paragraph 8 C. on page 16 of P&T Committee minutes for criteria)

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

C. COMMITTEE ACTION: Because a substantial number of patients are currently receiving either sildenafil or tadalafil (128,007 patients, 90% of all patients receiving PDE-5 inhibitors), the P&T Committee recommended (17 for, 1 opposed, 1 abstained) an effective date no later than the first Wednesday following a 90-day implementation period. The implementation period will begin immediately following the approval by the Director, TMA. (See paragraph 8 D. on pages 16-17 of P&T Committee minutes for rationale.)

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

D. COMMITTEE ACTION: Based on the relative clinical and cost effectiveness analyses, the P&T Committee recommended placing vardenafil on the Extended Core Formulary (ECF) (17 for, 0 opposed, 1 abstained, 1 absent). Because there are no other formulary PDE-5 inhibitors on the UF, MTFs are prohibited from adding additional PDE-5 inhibitor(s) to their local formularies. (See paragraph 8 E. on page 17 of P&T Committee minutes for rationale.)

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

9. ANGIOTENSIN-CONVERTING ENZYME (ACE) INHIBITOR DRUG CLASS REVIEW

Portions of the clinical review were presented to the P&T Committee. The Committee provided expert opinion regarding clinical outcomes of importance for the purpose of developing an appropriate cost effectiveness model. Two ACE inhibitors, available as multisource generics for approximately two years, recently suspended manufacturing secondary to litigation results. The Committee will seek pricing information from the companies representing the name brand version of these products. Both the clinical and cost effectiveness analyses will be completed during the August 2005 meeting; no action necessary.

10. MULTIPLE SCLEROSIS DISEASE MODIFYING DRUG (MS-DMD) CLASS REVIEW

The P&T Committee evaluated the relative clinical effectiveness and cost effectiveness of the four MS-DMDs: intramuscular interferon (IFN) beta-1a (Avonex), subcutaneous IFN beta-1a (Rebif), subcutaneous IFN beta-1b (Betaseron), and the subcutaneous polypeptide mixture glatiramer acetate (Copaxone). MS-DMDs have been available for the past 12 years and the class is currently ranked 33rd in MHS drug class expenditures. During a twelve-month period ending 31 January 2005, approximately 6,500 patients were prescribed a MS-DMD. In most cases MS-DMDs are prescribed by sub-specialists (neurologists).

A. COMMITTEE ACTION: The P&T Committee, based upon its collective professional judgment, voted to accept the conclusion that none of the MS-DMDs have a significant clinically meaningful therapeutic advantage in terms of safety, tolerability and effectiveness over the other MS-DMDs. (See paragraph 10 A. on pages 17-18 of P&T Committee minutes for rationale.) The P&T Committee also concluded that the overall average weighted cost per day of therapy for the MS-DMDs was lowest for Avonex. (See paragraph 10 B. on page 18 of P&T Committee minutes for rationale.) Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of the MS-DMDs, and other relevant factors (i.e., relative uniqueness of each agent in patient therapy and the low expectation that patient behavior would be affected by formulary status), the P&T Committee voted (18 for, 0 opposed, 0 abstained) to recommend formulary status for all four MS-DMDs:

IFN beta-1a (Avonex), IFN beta-1a (Rebif), IFN beta-1b (Betaseron), and glatiramer (Copaxone) under the UF.

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

B. COMMITTEE ACTION: Based on the relative clinical and cost effectiveness analyses, the P&T Committee recommended placing IFN beta-1a (Avonex) on the ECF (18 for, 0 opposed, 0 abstained). MTFs may add additional MS-DMDs to their local formularies if needed to meet the needs of their specific patient populations. (See paragraph 10 E. on page 19 of P&T Committee minutes for rationale.)

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

APPENDIX A – TABLE 1: PROCESSES AND RECOMMENDATION/APPROVAL AUTHORITIES

APPENDIX B – TABLE 2: NEWLY APPROVED DRUGS

APPENDIX C – DoD P&T COMMITTEE INTERIM MEETING: DERMATOLOGICAL TOPICAL ANTIFUNGAL DRUG CLASS REVIEW

The P&T Committee evaluated the relative clinical effectiveness and cost effectiveness of the 11 dermatological topical antifungals marketed in the U.S. by considering information regarding their safety, tolerability, effectiveness, and other factors, including marketed formulations, generic availability, chemical structures, existing MHS utilization patterns, and Food and Drug Administration (FDA)-approved labeling. The dermatological topical antifungal class was defined as the "azoles" clotrimazole (various generics), econazole (various generics), ketoconazole (various generics), miconazole (various generics), oxiconazole (Oxistat), sertaconazole (Ertaczo), and sulconazole (Exelderm); the "allylamines" butenafine (Mentax) and naftifine (Naftin); the "substituted pyridone" ciclopirox (Loprox); and the "polyene" nystatin. The topical formulation of terbinafine (Lamisil) was specifically excluded from the class, as it is now solely available in a non-prescription product.

A. COMMITTEE ACTION: The P&T Committee concluded that none of the topical antifungals have significant, clinically meaningful therapeutic advantage in terms of safety, effectiveness, or clinical outcome over the other topical antifungals. (See APPENDIX C, part A. on pages 23-24 of P&T Committee minutes for rationale). The P&T Committee concluded that econazole, sulconazole, ciclopirox, oxiconazole, and sertaconazole are not cost effective relative to nystatin, miconazole, clotrimazole, ketoconazole, butenafine, and naftifine. (See APPENDIX C, part B. on pages 24-26 of P&T Committee minutes for rationale). Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness analysis of the topical antifungal agents, the P&T Committee voted (11 for, 1 opposed, 1 abstained) to recommend formulary status for nystatin, miconazole, clotrimazole, ketoconazole, butenafine, and naftifine; and non-formulary status for econazole, sulconazole, ciclopirox, oxiconazole, and sertaconazole under the UF.

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

B. COMMITTEE ACTION: Based on the clinical evaluations of econazole, sulconazole, ciclopirox, oxiconazole, sertaconazole, and the conditions for establishing medical necessity for a non-formulary medication provided for in the UF rule, the P&T Committee recommended medical necessity criteria for econazole, sulconazole, ciclopirox, oxiconazole, and sertaconazole (12 for, 0 opposed, 1 abstained). (See APPENDIX C, part C. on page 26 of P&T Committee minutes for criteria)

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

C. COMMITTEE ACTION: Because topical antifungal products are used to treat acute (rather than chronic) infections, patients are unlikely to require a change in existing therapy. For this reason the P&T Committee recommended (12 for, 0 opposed, 1 abstained) an effective date no later than the first Wednesday following a 30-day implementation period. The implementation period will begin immediately following the approval by the Director, TMA. (See APPENDIX C, part D. on page 26 of P&T Committee minutes for rationale.)

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

D. *COMMITTEE ACTION:* Based on the relative clinical and cost effectiveness analyses, the P&T Committee recommended placing clotrimazole and nystatin on the BCF (12 for, 0 opposed, 1 abstained). MTFs may add additional UF topical antifungal agents to their local formularies if needed to meet the needs of their specific patient populations. (See APPENDIX C, part E. on pages 26-27 of P&T Committee minutes for rationale.)

*Director, TMA, Decision***:** ■ Approved □ Disapproved

Approved, but modified as follows:

DECISION ON RECOMMENDATIONS

Director, TMA, decisions are as annotated above.

// William Winkenwerder, Jr.//
William Winkenwerder, Jr., M.D.
Date: 14 July 2005

Department of Defense
Pharmacy and Therapeutics Committee Minutes

19 May 2005

1. CONVENING

The DoD P&T Committee convened at 0800 hours on 17, 18, and 19 May 2005 at the DoD Pharmacoeconomic Center, Fort Sam Houston, Texas.

2. ATTENDANCE

A. Voting Members Present

CAPT Patricia Buss, MC, USN	DoD P& T Committee Chair
CDR Mark Richerson, MSC, USN	DoD P& T Committee Recorder
MAJ Travis Watson, MS, USA	Director, DoD Pharmacy Programs, TMA
Maj Michael Proffitt, MC	Air Force, OB/GYN Physician
Maj Nicholas Conger, MC	Air Force, Internal Medicine Physician
Maj Charlene Reith, BSC (for Col Philip Samples, BSC)	Air Force, Pharmacy Officer
LtCol Brian Crownover, MC	Air Force, Physician at Large
CDR William Hall, MC (via VTC)	Navy, Internal Medicine Physician
LCDR Roger Akins, MC (via VTC)	Navy, Pediatrics Physician
CDR Brian Alexander, MC (via VTC)	Navy, Physician at Large
LCDR Joseph Lawrence, MSC	Navy, Pharmacy Officer
COL Doreen Lounsbery, MC	Army, Internal Medicine Physician
MAJ Roger Brockbank, MC	Army, Family Practice Physician
COL Barry Sheridan, MC (for COL Joel Schmidt, MC)	Army, Physician at Large
COL Kent Maneval, MS (for COL Isaiah Harper, MS)	Army, Pharmacy Officer (Defense Medical Standardization Board)
CDR Vernon Lew	Coast Guard, Pharmacy Officer
LTC Donald DeGroff, MS, USA	Contracting Officer Representative, TMOP
CDR Jill Pettit, MSC, USN	Contracting Officer Representative, TRRx
Joe Canzolino (present May 17th only)	Department of Veterans Affairs

B. Voting Members Absent

None	

C. Non-Voting Members Present

Lynn Burleson	Deputy General Counsel, TMA
Martha Taft	Resource Management Directorate, TMA

3. REVIEW MINUTES OF LAST MEETING

Dr. William Winkenwerder, Jr., M.D. approved the minutes of the DoD Pharmacy and Therapeutics (P&T) Committee held February 2005 on April 18, 2005.

4. INTERIM DECISIONS/ADMINISTRATIVE ISSUES

A. The February 2005 DoD Pharmacy and Therapeutics Committee Minutes (Table 1: Process and Recommendations/Approval Authorities) - The P&T Committee developed a comprehensive list of functions associated with formulary management and categorized each in one of three decision processes outlined in Table 1 (Appendix A). Under 10 U.S.C. § 1074g and 32 C.F.R. 199.21, recommendations to the Director, TMA, on formulary status, preauthorizations, and the effective date for a drug's change from formulary to non-formulary status must be reviewed by the Beneficiary Advisory Panel (BAP) before the Director may make a final decision. Establishment and changes to

medical necessity criteria are not required to be reviewed by the BAP before the Director makes a final decision. An administrative clarification was made to the table as follows:

- **Approval by Director, TMA required based on DoD P&T Committee recommendations and BAP Comments**
  - Bullet: "Changes to the existing prior authorizations and medical necessity criteria (e.g., due to the availability of new efficacy or safety data)"
  - Was changed to: "Changes to existing prior authorizations (e.g., due to the availability of new efficacy or safety data)"
- **Approval by Director, TMA required based on Committee recommendations**
  - Bullet: "Establishment of medical necessity criteria for non-formulary agents"
  - Was changed to: "Establishment and changes to existing medical necessity criteria for non-formulary agents"

B. DoD P&T Committee Charter – Legal counsel stated that the wording of the DoD P&T Committee Charter is silent regarding the ability of alternate DoD P&T members to vote in the absence of the primary member. CAPT Buss stated that the following change to the charter has been proposed: Each voting member and non-voting member may have a designated alternate who can represent the member, including voting (if representing a voting member), at P&T Committee meetings in the event the member cannot attend.

C. Quantity Limit for Azelastine (Astelin) – Quantity limits for azelastine were set at the February 2005 DoD P&T meeting as 1 bottle per 30 days (retail), and 3 bottles per 90 days (mail order). The intent of the previous quantity limit was to provide 30-day increments of the medication under standard dosing regimens. However, because of priming requirements for initial and intermittent use, one bottle will not last for 30 days if used continuously under the standard dosing regime. Administrative adjustment of the azelastine quantity limits are as follows: 2 bottles per 30 days, 3 bottles per 60 days, and 4 bottles per 90 days. (ESI standard is 4 bottles per 90 days).

5. ITEMS FOR INFORMATION

TRICARE Management Activity (TMA) and DoD Pharmacoeconomic Center (PEC) staff members briefed the P&T Committee on the following:

A. Angiotensin Receptor Blocker (ARB) Drug Class Review Clarification: The P&T Committee's Uniform Formulary (UF) recommendations documented in the February 2005 minutes and approved by Dr. Winkenwerder include each of the listed ARBs and their respective combinations with hydrochlorothiazide. As a result, both eprosartan (Teveten) and eprosartan / hydrochlorothiazide (Teveten HCT) were designated as non-formulary under the UF, and both telmisartan (Micardis) and telmisartan / hydrochlorothiazide (Micardis HCT) were placed on the Basic Core Formulary (BCF).

B. Beneficiary Advisory Panel (BAP) Briefing: TMA briefed the members of the DoD P&T committee regarding the March 23, 2005 BAP meeting. The Committee was briefed on BAP comments regarding DoD P&T Committee's UF and implementation recommendations.

C. Extension of Expiration Dates for Selected Agents Requiring Prior Authorization (PA): DoD PA criteria are currently established for agents within eight drug classes. These include: antifungals for onychomycosis [Lamisil (terbenafine), Penlac (ciclopirox), Sporanox (itraconazole)]; Enbrel (etanercept); fertility medications

(injectable gonadotropins); growth hormone (somatropin, somatrem); Humira (adalimumab); Kineret (anakinra); phosphodiesterase-5 (PDE-5) inhibitors [Cialis (tadalafil), Levitra (vardenafil), and Viagra (sildenafil)]; and Raptiva (efalizumab). When a PA is granted for any of these agents, the maximum duration of the PA is for one year.

Currently the contractor for TRICARE Mail Order Pharmacy (TMOP) and TRICARE Retail Pharmacy (TRRx) programs re-establishes the PA for each of these agents in these eight drug classes annually for the same fee that is negotiated for conducting the initial PA. Because the responses to the PA criteria established for some of these agents are not expected to change over time, re-establishing the PA for some of these agents annually will no longer be required, thus saving DoD the recurrent PA processing costs. As of June 1, 2005, these specific medications will no longer have a maximum one year expiration date and all existing PAs for them will have their current annual expiration date removed: Enbrel (etanercept); Humira (adalimumab); Kineret (anakinra); PDE-5 inhibitors (tadalafil, vardenafil, and sildenafil); and Raptiva (efalizumab).

D. Determining Medical Necessity for Non-Formulary Medications – PEC staff provided the DoD P&T Committee with an update concerning the medical necessity process for medications designated as non-formulary under the UF process. Important points included:

- Spouses, family members, and retirees do not need a medical necessity determination in order to fill prescriptions for non-formulary medications at the $22 non-formulary cost share through retail network pharmacies or mail order. They may fill prescriptions for non-formulary medications at the lower formulary cost share ($9) if the non-formulary medication is determined to be medically necessary.
- Active duty service members, who pay no cost shares, may not fill prescriptions for a non-formulary medication unless it is determined to be medically necessary. If the non-formulary medication is determined to be medically necessary, active duty service members may fill prescriptions at $0 cost share.
- Military Treatment Facilities (MTFs) will be able to fill non-formulary requests for non-formulary medications only if both of the following conditions are met: 1) a MTF provider writes the prescription, and 2) medical necessity is established for the non-formulary medication. MTFs may (but are not required to) fill a prescription for a non-formulary medication written by a non-MTF provider to whom the patient was referred, as long as medical necessity has been established.
- Medical necessity criteria established by the DoD P&T Committee for medications designated as non-formulary under the UF apply to all three points of service (MTFs, mail order, retail). Medical necessity determinations are portable between the TMOP and the retail pharmacy network and have no expiration date.
- If an MTF fills a prescription for a medication designated as non-formulary under the UF process, the assumption is made that the MTF determined that it is medically necessary for the beneficiary to receive the non-formulary medication based on the criteria established by the DoD P&T Committee. An override is established in the patient's electronic medication profile and the beneficiary may then receive the non-formulary medication at the formulary cost share from either the retail pharmacy network or TMOP.
- According to the UF rule, information supporting medical necessity for use of a non-formulary medication may be provided at a later date (no later than 60 days

from the dispensing date), as an appeal to reduce the cost share for that prescription fill. Procedures are currently being developed to meet this requirement as of July 17, 2005, the effective date for the first medications designated as non-formulary under the UF process.

- More information, including medical necessity criteria and forms, is available on the TRICARE pharmacy website at: www.tricare.osd.mil/pharmacy/medical-nonformulary.cfm. Information on the formulary status and availability of specific medications is available by using the TRICARE Formulary Search Tool (www.tricareformularysearch.org).

E. PDE-5 Inhibitor PA Review – Mr. Dave Flowers presented a review of the status of the PDE-5 inhibitor PA with regard to frequency of requests, approval rate, and sentinel effect.

Frequency: At TRRx and TMOP, there were approximately 680 requests for PDE-5 PAs in the month of March 2005. This amount had been increasing slightly over the prior several months, gradually rising to this level from approximately 500 requests in the month of September 2004.

A significant reduction in the number of PA requests occurred beginning in mid-August 2004. From June 2004 through August 2004, an average of over 3,000 requests occurred each month. The reduction beginning in August was attributed to the automatic granting of PDE-5 inhibitor coverage to all males age 50 or over. This change was effective in Pharmacy Data Transaction Service (PDTS) on August 20, 2004, and as a result, no males age 50 or over have been required to follow the PA process in order to obtain these products.

***Approval* Rate:** Over the past ten months (June 2004 through March 2005), approximately 94% of all beneficiaries requesting PA for PDE-5 inhibitors were granted approval. When the PA requests were denied, there were three most commonly reported reasons. These reasons are presented below, in descending order of occurrence:

- PDE-5 is not being used for treatment of erectile dysfunction of organic origin
- PDE-5 is not being used for a male
- PDE-5 is not being used for the treatment of sexual dysfunction

Sentinel Effect: There are several measures that can be used to assess the impact of PA criteria. Frequency of occurrence, approval rate, and examining denial reasons are all common measures that represent components of a good approach to assess how many beneficiaries initiated the PA process, what was the eventual result, and why were these requests approved or denied.

An additional measure is assessing how many unique beneficiaries presented a prescription for a PDE-5 inhibitor in the TRRx and/or TMOP pharmacies, had this prescription rejected by PDTS at the point of service, and then chose not to initiate the formal PA approval process by submitting either the required forms, or having their provider contract the PA review team.

It was observed that there was a very large number of beneficiaries who elected to not initiate the necessary formal steps to obtain PA after receiving a rejection for a PDE-5 prescription at a TRRx or TMOP pharmacy.

The results for the first calendar quarter of 2005 (January through March 2005) are presented below:

- 5,176 = Beneficiaries with unique transaction rejects in PDTS requiring PA
- 1,829 = Beneficiaries entering the PA process
- 1,711 = Beneficiaries awarded a PA

6. REVIEW OF RECENTLY- APPROVED AGENTS

The PEC presented clinical information on three new medications approved by the FOOD AND DRUG ADMINISTRATION (FDA) and introduced to the U.S. market since February 2005 (Table 2 – Appendix B). Since none of the new medications fall into drug classes already reviewed by the P&T Committee, UF consideration was deferred until drug class reviews are completed.

The Committee discussed the potential need for a PA requirement for pramlintide (Symlin) subcutaneous injection, which presents some unique concerns regarding appropriate patient selection, dosing, administration, potential for interaction with other medications, and required adjustment of insulin dosing due to the potential for severe hypoglycemia. The Committee agreed (11 for, 6 opposed, 2 abstained) that a PA recommendation should be considered for pramlintide and requested that the PEC develop PA criteria to be reviewed at the next meeting.

The Committee also discussed concerns regarding availability of pramlintide through the TMOP given the black box warning and safety issues, but agreed (9 for, 7 opposed, 3 abstained) that it should be available through the TMOP. The Committee requested more complete information about the manufacturer's plan to target use to appropriate patients, which was not available at the time of the meeting.

7. BCF CLARIFICATION OF RECENTLY APPROVED DRUGS

The DoD P& T Committee reviewed the relative clinical and cost effectiveness of the following recently approved formulations of medications already listed on the BCF.

A. Alendronate 70 mg /cholecalciferol (vitamin D) 2800 IU (Fosamax Plus D)

The current BCF listing for alendronate includes all oral strengths except 40 mg tablets, which are indicated only for the treatment of Paget's disease. Currently, the majority of use across DoD is the weekly formulations of alendronate (35- and 70-mg tablets). Addition of vitamin D, which is required for normal bone formation, to alendronate may provide a clinical advantage for patients who have inadequate dietary intake of vitamin D and insufficient exposure to sunlight. It is difficult to quantify this advantage, since many patients will also require supplemental calcium, which is readily available in combination with vitamin D. However, taking in account the manufacturer's offer to add alendronate plus D to the current BPA for alendronate without an increase in price and the fact that the product is not expected to delay the availability of generic versions of alendronate or alendronate plus vitamin D, the Committee agreed that the product offers a clinical advantage to MTF patients at no additional cost.

COMMITTEE ACTION: The Committee recommended adding alendronate plus D to the BCF (17 for, 1 abstained, 1 absent).

B. Fluticasone Propionate HFA (Flovent HFA)

The current BCF listing is for fluticasone oral inhaler. The manufacturer is no longer manufacturing the chlorofluorocarbon (CFC)-containing product (Flovent) and is

replacing it with a hydrofluoroalkane (HFA)-containing product (Flovent HFA). Since the product is now the only fluticasone metered dose inhaler available and since the HFA product does not appear to offer any clinical disadvantages compared to the CFC product, the Committee agreed that there was no need to clarify the current BCF listing. As of May 2005, the Flovent HFA metered dose inhaler was available to MTFs and TMOP at the same price as the old CFC formulation.

C. Insulin Glargine (Lantus) 100 u/mL 3 mL Cartridges

The current BCF listing is for insulin glargine injection (Lantus), which was previously available only as a 10 mL vial. The 3 mL cartridges are designed for use with the manufacturer's OptiClik device. The Committee agreed that while this device may benefit some patients (e.g., patients who are needle-phobic or visually impaired), the number of patients who would benefit represents only a small percentage of patients using insulin glargine. The Committee noted that, overall, about 92% of insulin use in DoD is vials, as compared to insulin pens, cartridges, and dispensing syringes which represent only 8% of use. The Federal Supply Schedule (FSS) price (as of May 2005) for Lantus was $25.70 for the 10 mL vial ($2.67 per mL) vs. $79.09 for a box of five 3 mL cartridges ($5.27 per mL). The Committee agreed that the potential clinical benefit associated with use of the cartridges was not sufficient to justify the additional cost.

COMMITTEE ACTION: The Committee recommended clarifying the current BCF listing for insulin glargine injection to exclude the 100 u/mL 3 mL cartridges (18 for, 1 abstained).

8. PHOSPHODIESTERASE (PDE-5) INHIBITOR DRUG CLASS REVIEW

A. **PDE-5 UF Clinical Effectiveness:** The P&T Committee evaluated the relative clinical effectiveness of all the FDA-approved PDE-5 inhibitors available in the U.S. The PDE-5 inhibitor therapeutic class was defined as sildenafil (Viagra), vardenafil (Levitra), and tadalafil (Cialis). The clinical review included consideration of pertinent information from a variety of sources determined by the P&T Committee to be relevant and reliable, including but not limited to sources of information listed in 32 C.F.R. 199.21(e)(1). The P&T Committee was advised that there is a statutory presumption that pharmaceutical agents in a therapeutic class are clinically effective and should be included on the UF unless the P&T Committee finds by a majority vote that a pharmaceutical agent does not have a significant, clinically meaningful therapeutic advantage in terms of safety, effectiveness, or clinical outcome over the other pharmaceutical agents included on the UF in that therapeutic class.

The P&T Committee agreed that in the Military Health System (MHS) PDE-5s are considered to be the gold standard for the treatment of erectile dysfunction (ED). During a twelve month period ending January 31, 2005, 142,333 patients were prescribed a PDE-5 Inhibitor. This class is now ranked 46th in MHS drug class expenditures.

*1.) Efficacy: A*ll PDE-5 inhibitors have FDA approved indications for the treatment of ED. There are no head-to-head trials comparing the three PDE-5 inhibitors. The available placebo controlled trials and meta-analyses were reviewed. Although all PDE-5s were found to be clinically effective when compared to placebo, variability in study design, demographics, and outcome measures precluded the ability to designate one PDE-5 as clinically superior. A difference in duration of action exists among these agents. There is no evidence to suggest clinical superiority based on these differences. In addition to its FDA-approved indication for ED, sildenafil has also

been proven safe and effective for the treatment of primary pulmonary hypertension. Another off-label use of sildenafil is in the setting of radical prostatectomy, but there is not currently reliable evidence supporting its effectiveness for this indication.

2.) *Safety/Tolerability:* The P&T Committee found that the PDE-5 inhibitors were not significantly different with respect to major contraindications, drug interactions, and adverse drug reactions. As of May 2005 all agents have similar alpha-blocker warnings and nitrate contraindications. Vardenafil has a drug interaction warning associated with patients taking Class IA or Class III antiarrhythmics. Sildenafil is associated with more visual side effects where tadalafil is associated with more back pain.

Conclusion: The P&T Committee concluded that all PDE-5 inhibitors have similar relative clinical effectiveness for treating erectile dysfunction. All three PDE-5 inhibitors have similar safety and tolerability profiles.

COMMITTEE ACTION: The P&T Committee voted (18 for, 0 opposed, 1 abstained) that for the purposes of the UF clinical review, none of the PDE-5 inhibitors have a significant clinically meaningful therapeutic advantage in terms of safety, effectiveness, or clinical outcome over the other PDE-5 inhibitors.

B. PDE-5 Inhibitor UF Relative Cost Effectiveness: In considering the relative cost effectiveness of pharmaceutical agents in this class, the P&T Committee evaluated the costs of the agents in relation to the safety, effectiveness, and clinical outcomes of the other agents in the class. Information considered by the Committee included but was not limited to sources of information listed in 32 C.F.R. 199.21(e)(2). Several analyses were used to determine the relative cost effectiveness of agents within the PDE-5 inhibitor therapeutic class. A pharmacoeconomic analysis using cost minimization techniques was used based on the clinical review conclusion that the efficacy, safety, and tolerability between all agents were roughly equivalent. A series of cost effectiveness analyses were then conducted to confirm the results of the cost-minimization analysis. Cost effectiveness analyses were also used to evaluate differences in the duration of action between the agents.

Results of the cost minimization and cost effectiveness analyses (CMA/CEA) showed vardenafil to be the most cost effective PDE-5 inhibitor across all points of service (MTF, TRRx, TMOP). This was true even when taking into consideration differences in the duration of action between the agents.

The results of the above analyses were then incorporated into a budget impact analysis (BIA), which accounted for other factors and costs associated with a potential decision regarding formulary status of PDE-5 inhibitors within the UF. These factors included: market share migration, cost reduction associated with non-formulary cost shares, medical necessity processing fees, and switch costs. The results of the budget impact analysis further confirmed the results of the CMA/CEA. Sildenafil and tadalafil were found not to be cost effective relative to vardenafil.

Conclusion: The P&T Committee concluded that sildenafil and tadalafil were not cost effective relative to vardenafil. Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of the PDE-5 inhibitors, the P&T Committee recommended that the status of sildenafil and tadalafil be changed from formulary to non-formulary on the UF, with vardenafil maintaining formulary status on the UF with the formulary cost share.

COMMITTEE ACTION: The P&T Committee agreed (18 for, 0 opposed, 1 abstained) with the relative cost effectiveness analysis of the PDE-5 inhibitors presented. The P&T Committee, based upon its collective professional judgment, voted (17 for, 0 opposed, 1 abstained, 1 absent) to recommend non-formulary status on the UF for sildenafil and tadalafil, with vardenafil maintaining formulary status on the UF at the formulary cost share.

C. PDE-5 Inhibitor UF Medical Necessity Criteria: Based on the clinical evaluation of sildenafil and tadalafil, and the conditions for establishing medical necessity for a non-formulary medication provided for in the UF rule, the P&T Committee recommended the following medical necessity criteria for these agents.

1.) Use of the formulary PDE-5 inhibitor (vardenafil) is contraindicated, and the use of either sildenafil or tadalafil is not contraindicated.

2.) The patient has experienced or is likely to experience significant adverse effects from the formulary PDE-5 inhibitor (vardenafil), and the patient is reasonably expected to tolerate either sildenafil or tadalafil.

3.) Use of the formulary PDE-5 inhibitor (vardenafil) resulted in therapeutic failure, and the patient is reasonably expected to respond to sildenafil or tadalafil [therapeutic failure as outlined on medical necessity form].

4.) The patient has previously responded to either sildenafil or tadalafil, and changing to vardenafil would incur unacceptable risk. This primarily pertains to patients requiring a PDE-5 inhibitor who have congenital or acquired QT prolongation or who are taking a Class IA (e.g., quinidine, procainamide) or Class III (e.g., amiodarone, sotalol) antiarhrhythmic medication.

5.) Use of the PDE-5 inhibitor is for primary pulmonary hypertension and there is no alternative formulary agent.

COMMITTEE ACTION: The P&T Committee voted (18 for, 0 opposed, 0 abstained) to approve the medical necessity criteria.

D. PDE-5 inhibitor UF Implementation Plan: Because a substantial number of patients are currently receiving either sildenafil or tadalafil from one of the three MHS pharmacy points of service (128,007 patients, 90% of all patients receiving PDE-5 inhibitors) the P&T Committee proposed a 90-day transition period for implementation of the decision to change sildenafil and tadalafil to non-formulary drugs on the UF. Patients wishing to fill prescriptions for sildenafil or tadalafil at retail network pharmacies or the TMOP would then have to pay the non-formulary cost share unless medical necessity for these agents is established by the beneficiary or their provider.

MTFs will not be allowed to have sildenafil or tadalafil on their local formularies. MTFs will be able to fill non-formulary requests for these agents only if both of the following conditions are met: 1) the prescription must be written by a MTF provider, and 2) the beneficiary provider must establish medical necessity for these agents. MTFs may (but are not required to) fill a prescription for sildenafil or tadalafil written by a non-MTF provider to whom the patient was referred, as long as medical necessity has been established.

COMMITTEE ACTION: The P&T Committee recommended (17 for, 1 opposed, 1 abstention) an effective date no later than the first Wednesday following a 90-day

implementation period. The implementation period will begin immediately following the approval by the Director, TMA.

E. PDE-5 Inhibitor Extended Core Formulary (ECF) Review and Recommendations: The P&T Committee had previously determined that only one PDE-5 inhibitor would be added to the ECF based on the clinical and cost effective reviews. Since only one PDE-5 inhibitor, vardenafil, was selected for UF status, it was recommended that this agent also be added to the ECF.

Conclusion: Vardenafil was recommended for inclusion on the ECF.

COMMITTEE ACTION: The P&T Committee voted (17 for, 0 opposed, 1 abstained, 1 absent) to recommend that vardenafil be on the ECF.

9. ANGIOTENSIN-CONVERTING ENZYME (ACE) INHIBITOR DRUG CLASS REVIEW

The DoD P&T Committee initiated the ACE inhibitor class review; however because price submissions were not complete, no action was taken. Two ACE inhibitors, available as multisource generics for approximately two years, recently suspended manufacturing secondary to litigation results. The Committee will seek pricing information from the companies representing the name brand version of these products. Continuation of the ACE inhibitor review will occur at the August 2005 DoD P&T Committee meeting.

10. MULTIPLE SCLEROSIS DISEASE MODIFYING DRUG (MS-DMD) CLASS REVIEW

A. MS-DMDs UF Relative Clinical Effectiveness: The P&T Committee evaluated the relative clinical effectiveness of the four MS-DMDs in the U.S. by considering information regarding their safety, effectiveness and clinical outcomes. Currently, MS-DMDs have been approved for the treatment of relapsing-remitting (RR) MS. The therapeutic class includes three interferons (IFN): intramuscular (IM) IFN beta-1a (Avonex), subcutaneous (SC) IFN beta-1a (Rebif), SC IFN beta-1b (Betaseron); and one subcutaneous (SC) polypeptide mixture, glatiramer acetate (Copaxone). The clinical review included consideration of pertinent information from a variety of sources determined by the P&T Committee to be relevant and reliable, including but not limited to sources of information listed in 32 C.F.R. 199.21(e)(1). The P&T Committee was advised that there is a statutory presumption that pharmaceutical agents in a therapeutic class are clinically effective and should be included on the UF unless the P&T Committee finds by a majority vote that a pharmaceutical agent does not have a significant, clinically meaningful therapeutic advantage in terms of safety, effectiveness, or clinical outcome over the other pharmaceutical agents included on the UF in that therapeutic class.

MS-DMDs have been available for the past 12 years and the class is currently ranked 33rd in MHS drug class expenditures. During a twelve-month period ending January 31, 2005, approximately 6,500 patients were prescribed a MS-DMD. In most cases MS-DMDs are prescribed by sub-specialists (neurologists).

1.) Efficacy for RR-MS: All the IFNs and glatiramer are indicated for the treatment of patients with relapsing forms of MS to decrease the frequency of clinical exacerbations. Avonex and Rebif also claim to delay accumulation of physical disability. A Cochrane systematic review of all the available trials through 2000 found only a modest reduction in exacerbations and disability following treatment of RR-MS with IFNs. A Cochrane systematic review of trials available through 2003 concluded that glatiramer had a modest reduction in exacerbations, but no beneficial

effect on disease progression. A decrease in exacerbations does not necessarily correlate to the progression of disease. There is no compelling evidence to support superiority of one agent over another. All beta IFNs and glatiramer have been shown to have a modest protective effect on disease exacerbations. IFN beta-1a agents (Rebif and Avonex) have shown to have a modest protective effect on disease disability; therefore they may have a marginal benefit over glatiramer.

2.) Safety/Tolerability: The P&T Committee agreed that there is no evidence that any one MS-DMD is preferable to the others with respect to safety or tolerability. These medications are generally well-tolerated and adverse events are dose-related. The most common side effects were local injection site reactions for the SQ drugs and flu-like symptoms for the IM drugs. Additionally, a self-limiting allergic-type reaction may be seen with glatiramer. All the MS-DMDs have similar safety and tolerability profiles with only rare incidences of true serious adverse effects.

Conclusion: The P&T Committee concluded that there is no compelling evidence to support superiority of one MS-DMD agent over another in the treatment of RR-MS. All MS-DMD agents have shown a modest effect in reducing exacerbations, with IFN beta-1a agents (Rebif and Avonex) demonstrating a modest reduction on disease disability. All the IFNs and glatiramer have similar safety and tolerability profiles.

COMMITTEE ACTION: The P&T Committee, based upon its collective professional judgment, voted (18 for, 0 opposed, 0 abstained) to accept the conclusion that none of the MS-DMDs have a significant clinically meaningful therapeutic advantage in terms of safety, effectiveness, or clinical outcomes over the other MS-DMDs.

B. MS-DMD UF Relative Cost Effectiveness: In considering the relative cost effectiveness of pharmaceutical agents in this class, the P&T Committee evaluated the costs of the agents in relation to the safety, effectiveness, and clinical outcomes of the other agents in the class. Information considered by the P&T Committee included but was not limited to sources of information listed in 32 C.F.R. 199.21(e)(2).

Cost-minimization techniques determined that the overall average weighted cost per day of therapy for the MS-DMDs was lowest for Avonex, followed by Copaxone and Betaseron. Rebif was determined to have the highest average weighted cost per treatment day.

Conclusion: Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of the MS-DMDs, and other relevant factors (i.e., relative uniqueness of each agent in patient therapy and the low expectation that patient behavior would be affected by formulary status), the P&T Committee recommended that all MS-DMDs [IFN beta-1a (Avonex), IFN beta-1a (Rebif), IFN beta-1b (Betaseron), and glatiramer acetate (Copaxone)] maintain UF status with the formulary cost share.

COMMITTEE ACTION: The P&T Committee, based upon its collective professional judgment, voted (18 for, 0 opposed, 0 abstained) to recommend formulary status for IFN beta-1b (Betaseron), IFN beta-1a (Avonex), IFN beta-1a (Rebif), and glatiramer (Copaxone) under the UF.

C. MS-DMD UF Medical Necessity Criteria: Since no agents were selected for non-formulary status on the UF, establishment of medical necessity criteria is not applicable.

D. MS-DMD UF Implementation Plan: Since no agents were selected for non-formulary status on the UF, establishment of an implementation plan is not applicable

E. MS-DMD ECF Review and Recommendations: The P&T Committee had previously determined that this class of drugs is more suitable for ECF due to the subspecialty nature of the MS-DMD class. The P&T Committee reviewed the MS-DMDs recommended for inclusion on the UF to select one MS-DMD for inclusion on the ECF. Cost-minimization techniques determined that the overall average weighted cost per day of therapy for the MS-DMDs was lowest for Avonex. PDTS data collected from October 1, 2001 to March 30, 2005 showed that Avonex has maintained the highest percent of MTF market share of all MS-DMDs. Based on the relative clinical and cost effectiveness analyses, the P&T Committee recommended placing Avonex on the ECF.

Conclusion: The P&T Committee concurred with the recommendation to place Avonex on the ECF based on its high MTF utilization and cost effectiveness

COMMITTEE ACTION: The P&T Committee voted (18 for, 0 opposed, 0 abstained) to recommend Avonex as the ECF agent.

11. ADJOURNMENT

The third day of the meeting adjourned at 1100 hours on May 19, 2005. The dates of the next meeting are August 16–18, 2005.

Appendix A – Table 1. Processes and Recommendation/Approval Authorities

Process	Function
Administrative (not part of DoD P&T Committee process, Beneficiary Advisory Panel (BAP) comments not required, Director, TMA, approval not required) Responsible parties include: TRICARE Mail Order Pharmacy and TRICARE Retail Pharmacy Contracting Officer Representatives (TMOP and TRRx CORs), TMA Pharmacy Program, TMA Office of General Counsel, and Pharmacoeconomic Center (PEC) staff	▪ Identification of new FDA-approved medications, formulations, strengths, package sizes, etc. ▪ If situation unclear, determination as to whether a new FDA-approved medication is covered by TRICARE ▪ If situation unclear, determination as to whether a new FDA-approved medication is part of the pharmacy benefit ▪ If situation unclear, determination as to whether a new FDA-approved medication is suitable for dispensing through the TRICARE Mail Order Pharmacy (TMOP) ▪ Calculating and implementing quantity limits if already established through the DoD P&T Committee process for a given medication or class of medications ▪ Making changes to quantity limits as needed based on non-clinical factors such as changes to packaging (e.g., medication previously available in boxes of 5 now only available packaged in boxes of 8) ▪ Establishing adjudication edits (PDTS limitations which are set well above the clinical maximum and are intended to prevent entry errors [e.g., entering a quantity of 17 for a 17-gram inhaler for which the actual unit of measure is 1 inhaler] or are intended to limit diversion) ▪ Implementing prior authorization requirements if already established through the DoD P&T Committee process for a given medication or class of medications ▪ Making minor changes to prior authorization forms NOT involving changes to underlying criteria, such as correcting contact information or rewording clinical questions ▪ Making changes to PA criteria, medical necessity criteria, quantity limits and any associated documents to accommodate new FDA-approved indications or respond to changes in FDA-recommended safety limitations (changes will be reviewed by DoD P&T Committee at next meeting) ▪ Removing medications withdrawn from the U.S. market from Basic Core Formulary (BCF) or Extended Core Formulary (ECF) listings and other documents ▪ Providing clarifications to existing listings on the BCF or ECF to specify specific brands/manufacturers when a joint DoD/VA mandatory source generic contract is awarded for a given product (i.e., clarifying an existing listing for “atenolol” to include the contractual requirement to use a specific manufacturer’s products) ▪ As necessary to accomplish functions above: for example, making changes to PDTS coding for TMOP & TRRx, communicating status of medications as part of the pharmacy or medical benefit to Managed Care Support Contractors (MCSCs), making changes to the TMA Pharmacy website and the TRICARE Formulary Search Tool, and making changes to BCF and ECF listings on the PEC website.
Approval by Director, TMA, required based on DoD P&T Committee recommendations and BAP comments	▪ Classification of a medication as non-formulary on the Uniform Formulary (UF), and implementation plan (including effective date) ▪ Establishment of prior authorization requirement for a medication or class of medications, summary/outline of prior authorization criteria, and implementation plan (including effective date) ▪ Changes to existing prior authorization (e.g., due to the availability of new efficacy or safety data) ▪ Discontinuation of prior authorization requirements
Approval by Director, TMA, required based on DoD P&T Committee recommendations (not required to be submitted to BAP for comments)	▪ Establishment of quantity limits for a medication or class of medications; deletion of existing quantity limits; changes to existing quantity limits based on clinical factors (e.g., new clinical data or dosing regimens) ▪ Establishment and changes of medical necessity criteria for non-formulary agents ▪ Addition, deletion of medications listed on the Basic Core Formulary (BCF) or Extended Core Formulary (ECF)

Appendix B – Table 2. Newly Approved Drugs

Medication & Mechanism of Action	FDA approval date; FDA-approved indications	Committee Recommendation
Pramlintide (Symlin; Amylin Pharm) injection; synthetic version of the neuro-endocrine hormone amylin, which complements the action of insulin by decreasing post-prandial glucose levels and slowing gastric emptying	Mar 05: *Type 1 DM*: as an adjunct treatment in patients who use mealtime insulin therapy and who have failed to achieve desired glucose control despite optimal insulin therapy *Type 2 DM*: as an adjunct treatment in patients who use mealtime insulin therapy and who have failed to achieve desired glucose control despite optimal insulin therapy, with or without a concurrent sulfonylurea agent and/or metformin Should be considered only for patients who have failed to achieve adequate glycemic control despite individualized insulin management and are receiving ongoing care under the guidance of a health care professional skilled in the use of insulin and supported by the services of a diabetes educator. Should NOT be considered for treatment of patients in the following categories: poor compliance with current insulin regimen; poor compliance with prescribed self-blood glucose monitoring; HbA1c >9%; recurrent severe hypoglycemia requiring assistance during the past 6 months; presence of hypoglycemia unawareness; confirmed diagnosis of gastroparesis; requirement for drugs that stimulate gastrointestinal motility; pediatric patients.	Prior authorization recommended due to safety concerns and the existing FDA requirements for risk minimization. Consideration of UF status deferred until drug class is reviewed.
Ibandronate Na (Boniva; Roche/GSK) 150 mg q month tabs; bisphosphonate; inhibits bone resorption	Mar 05: Treatment and prevention of osteoporosis in postmenopausal women	No UF recommendation at this meeting. Consideration of UF status deferred until drug class is reviewed.
Eszopiclone (Lunesta: Sepracor) tabs (control schedule IV); non-benzodiazepine sedative hypnotic	Dec 04: Treatment of insomnia. In controlled outpatient and sleep laboratory studies, Lunesta administered at bedtime decreased sleep latency and improved sleep maintenance	No UF recommendation at this meeting. Consideration of UF status deferred until drug class is reviewed.

Appendix C – DoD P&T Committee Interim Meeting: Topical Antifungal Drug Class Review

The P&T Committee held an interim electronic meeting during the period June 3, 2005 through June 6, 2005, during which it completed the class review that had been initiated during the May meeting of the Committee. A quorum of thirteen Committee voting members participated.

DERMATOLOGICAL TOPICAL ANTIFUNGAL DRUG CLASS REVIEW

A. Topical Antifungal UF Relative Clinical Effectiveness: The P&T Committee evaluated the relative clinical effectiveness of the 11 dermatological topical antifungals marketed in the US by considering information regarding their safety, tolerability, effectiveness, and other factors, including marketed formulations, generic availability, chemical structures, existing MHS utilization patterns, and FDA-approved labeling. The dermatological topical antifungal class was defined as the "azoles" clotrimazole (various generics), econazole (various generics), ketoconazole (various generics), miconazole (various generics), oxiconazole (Oxistat), sertaconazole (Ertaczo), and sulconazole (Exelderm); the "allylamines" butenafine (Mentax) and naftifine (Naftin); the "substituted pyridone" ciclopirox (Loprox); and the "polyene" nystatin. The topical formulation of terbinafine (Lamisil) was specifically excluded from the class, as it is now solely available in a non-prescription product. The clinical review included consideration of pertinent information from a variety of sources determined by the P&T Committee to be relevant and reliable, including but not limited to sources of information listed in 32 C.F.R. 199.21(e)(1). The P&T Committee was advised that there is a statutory presumption that pharmaceutical agents in a therapeutic class are clinically effective and should be included on the UF unless the P&T Committee finds by a majority vote that a pharmaceutical agent does not have a significant, clinically meaningful therapeutic advantage in terms of safety, effectiveness, or clinical outcome over the other pharmaceutical agents included on the UF in that therapeutic class.

1.) *Other Factors: Structure/Mechanism of action:* The Committee agreed that it would be advantageous to include on the UF products that are available in more than one formulation, products that have differing mechanisms of action (e.g., an allylamine and an azole), products that have a wide number of FDA-approved indications, and products that are approved for use in the pediatric population.

2.) *Efficacy for tinea pedis:* A Cochrane systematic review for treatment of tinea pedis infections reported that allylamines were slightly more efficacious than the azoles; however, there was a language bias present, and the overall cure rates were similar (80% cure rates with the allylamines vs. 73% with the azoles). Ciclopirox showed similar efficacy as clotrimazole. There was no difference in cure rates when azoles were compared to azoles, or when allylamines were compared to allylamines. Three topical antifungals were not included in the Cochrane review: ketoconazole, oxiconazole and sertaconazole. The cure rates reported in clinical trials with use of ketoconazole for tinea pedis are similar to those reported with the other azoles. Head-to-head trials comparing ketoconazole shampoo to ciclopirox shampoo for treating seborrheic dermatitis reported no differences in efficacy. Head-to-head trials of oxiconazole to naftifine and terbinafine show similar efficacy. Cure rates reported

with sertaconazole were low (30%) in the clinical trials used to gain FDA approval; however the FDA now has more stringent requirements for definitions of mycological cure than were used previously. Overall, there is no evidence to support that one individual topical antifungal agent is superior to another for treating tinea pedis.

3.) *Efficacy for tinea cruris, tinea corporis, or pityriasis versicolor*: There are no systematic reviews and no head-to-head trials of individual topical antifungal agents for treating tinea cruris, tinea corporis or pityriasis versicolor. There is no evidence that any one topical antifungal agent is superior to another for treating these conditions.

4.) *Efficacy for cutaneous candidiasis*: There are no systematic reviews for the treatment of cutaneous candidiasis. Two head-to-head trials comparing nystatin to miconazole and nystatin to tolnaftate showed similar efficacy. There is no evidence that any one topical antifungal agent is superior to another for treating cutaneous candidiasis.

5.) *Safety/Tolerability*: The topical antifungals are recognized as safe therapeutic agents. Several of the products (clotrimazole, miconazole, butenafine) are available without a prescription in the same concentration and dosage form as the prescription product. Hypersensitivity is the only contraindication listed in the package inserts of the topical antifungals. Adverse reactions reported most commonly with the topical antifungals include itching, burning, and erythema, which are the common symptoms of fungal infections. Adverse event rates listed in the individual agents' product labeling range from 1-3%. Products containing propylene glycol may cause burning, but this varies with the dosage form and type of infection being treated.

Conclusion: The Committee concluded that the topical antifungals have similar safety and tolerability profiles. The individual topical antifungal agents appear to have similar efficacy and clinical outcomes for treating tinea pedis, tinea corporis, tinea cruris, pityriasis versicolor, and cutaneous candidiasis infections. Differences do exist in such factors as existing MHS utilization, available formulations, FDA-approved indications, pediatric labeling and dosing duration.

COMMITTEE ACTION: The Committee voted (12 for, 0 opposed, 1 abstained) to recommend that, for the purposes of the UF, none of the topical antifungals have significant, clinically meaningful therapeutic advantage in terms of safety, effectiveness, or clinical outcome over the other topical antifungals. The UF recommendation can be based on cost, current utilization patterns, available formulations, pediatric indications, and dosing duration. The Committee also recommended having agents with differing mechanisms of action (azoles and allylamines) on the UF. The FDA-approved indications, clinical use, and dosing duration of ciclopirox is more similar to that of the azoles, rather then the allylamines; thus for cost effectiveness determinations, ciclopirox was considered along with the azoles.

B. Topical Antifungal UF Relative Cost Effectiveness: The P&T Committee evaluated the relative cost effectiveness of the agents within the topical antifungal class in relation to safety, tolerability, effectiveness, and clinical outcomes of the other agents in the class. Information considered by the P&T Committee included but was not limited to sources of information listed in 32 C.F.R. 199.21(e)(2). To determine the relative cost effectiveness of the agents within the topical antifungal therapeutic class, two separate

economic analyses were performed: A pharmacoeconomic analysis and budget impact analysis (BIA). From the preceding relative clinical effectiveness evaluation, the P&T Committee agreed that there was no compelling evidence to support clear superiority of one agent over another in terms of safety, effectiveness or clinical outcomes. For the UF, it would be advantageous to include products with differing mechanisms of action (e.g., an allylamine and an azole), those available in multiple dosage formulation, those approved for use in the pediatric setting, and those with existing high utilization in the MHS. The clinical characteristics of the substituted pyridone ciclopirox are more closely related to the azole topical antifungals than the allyalmines. For the purposes of the relative clinical effectiveness evaluation, topical antifungals with the azole and substituted pyridone (ciclopirox) structure were analyzed collectively; those agents with an allylamine structure were also analyzed separately from the azoles/substituted pyridone.

Given this conclusion, two cost-minimization analyses (CMAs) were conducted for each sub-class using two different measures of cost; the weighted average cost per gram and the weighted average annual cost of treatment per unique user. In general, the results of the CMAs revealed that: miconazole was the most cost effective agent in the azole/ substituted pyridone sub-class; naftifine and butenafine were similar in relative cost effectiveness in the allylamine sub-class; and nystatin was the most cost effective agent relative to all topical antifungals. More specifically, within the allylamine sub-class, naftifine was more cost effective than butenafine at the MTF and TMOP point of service (POS), whereas butenafine was more cost effective relative to naftifine at the TRRx POS. Examination of the cost continuum further suggested that a cluster of agents (nystatin, miconazole, clotrimazole, and ketoconazole) were more cost effective relative to the other agents within the therapeutic class (butenafine, ciclopirox, econazole, naftifine, oxiconazole, sertaconazole, and sulconazole). The results of the CMA were subsequently incorporated into a BIA. A BIA accounts for other factors and costs associated with a potential decision to recommend that the status of one or more topical antifungals be changed from formulary to non-formulary such as: market share migration, cost reduction associated with non-formulary cost shares, and medical necessity processing fees. The goal of the BIA was to identify a group of antifungal agents to be included on the UF which best met the majority of the clinical needs of the DoD population at the lowest cost to the MHS, given the DoD P&T Committee's decision to include on the UF at least one-agent from the azole/substituted pyridone sub-class, one agent from the allylamine sub-class, and nystatin. The BIA results revealed that a group of topical antifungals comprising nystatin, miconazole, clotrimazole, ketoconazole, butenafine, and naftifine best achieved this goal when compared to other combination groups of antifungals, and thus this group was determined to be more cost effective relative to other combination groups. The P&T Committee concluded that ciclopirox, econazole, oxiconazole, sertaconazole, and sulconazole were not cost effective relative to the other topical antifungals.

Conclusion: Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of the topical antifungals, the P&T Committee recommended that the status of econazole, sulconazole, ciclopirox, oxiconazole, and sertaconazole be changed from formulary to non-formulary, with

butenafine, clotrimazole, ketoconazole, miconazole, naftifine, and nystatin maintaining formulary status with the formulary cost share.

COMMITTEE ACTION: The P&T Committee agreed (12 for, 0 opposed, 1 abstained) with the relative cost effectiveness analysis of the topical antifungal agents presented. The P&T Committee, based upon its collective professional judgment, voted (11 for, 1 opposed, 1 abstained) to recommend formulary status for nystatin, miconazole, clotrimazole, ketoconazole, butenafine, and naftifine, and non-formulary status for ciclopirox, econazole, oxiconazole, sertaconazole, and sulconazole under the UF.

C. Medical Necessity Criteria: Based on the clinical evaluation of the topical antifungals and the conditions for establishing medical necessity for a non-formulary medication provided for in the UF rule, the following medical necessity criteria were proposed for the non-formulary topical antifungals.

1.) Use of the formulary topical antifungals (clotrimazole, ketoconazole, miconazole, naftifine, butenafine and nystatin) is contraindicated, and the use of the non-formulary topical antifungal is not contraindicated.

2.) The patient has experienced or is likely to experience significant adverse effects from all the formulary topical antifungals (clotrimazole, ketoconazole, miconazole, naftifine, butenafine and nystatin), and the patient is reasonably expected to tolerate the non-formulary topical antifungal.

3) Use of the formulary topical antifungals (clotrimazole, ketoconazole, miconazole, naftifine, butenafine and nystatin) resulted in therapeutic failure following administration for the appropriate duration of therapy (2 weeks for an allylamine and 4 weeks for an azole), and the patient is reasonably expected to respond to the non-formulary topical antifungal.

4.) The criterion that "the patient has previously responded to a non-formulary topical antifungal, and changing to a formulary topical antifungal would incur unacceptable risk" does NOT apply to this class as there are few safety concerns with topical antifungals, treatment is usually well tolerated, and therapy is generally limited to single treatment courses.

5) The criterion that "there are no formulary alternatives" does NOT apply to this class, as six topical antifungals are recommended for inclusion on the UF.

COMMITTEE ACTION: The Committee voted (12 for, 0 opposed, 1 abstained) to recommend the medical necessity criteria for the non-formulary topical antifungals.

D. Implementation Plan: The Committee voted (12 for, 0 opposed, 1 abstained) to recommend an effective date of the first Wednesday after 30 days from the final decision date (the date that DoD P&T Committee minutes are signed by the Director, TMA, approving the Committee's recommendation). A 30-day implementation period is recommended, since the topical antifungal products are used to treat acute (rather than chronic) infections, thus patients are unlikely to require a change in existing therapy.

E. Topical Antifungal BCF Review and Recommendations: The P&T Committee reviewed the topical antifungals recommended for inclusion on the UF to select the BCF topical antifungals. It had previously been decided that at least two, but no more than

three topical antifungals, could be added to the BCF, based on the outcome of relative clinical effectiveness and relative cost effectiveness determinations.

There are currently no topical antifungal products on the BCF. Since no BCF prices were submitted for any of the topical antifungals, the DoD P&T Committee evaluated the relative cost effectiveness for BCF selection based on the cost effectiveness information provided for the UF formulary recommendation. Although the CMA revealed that miconazole (#4 in utilization at the MTF at 2,000 Rxs/month) was more cost effective than clotrimazole, the difference was determined to be negligible. From a clinical and economic standpoint, clotrimazole is a rational selection for the BCF due to its wide number of FDA-approved indications (tinea pedis, tinea cruris, tinea "pityriasis" versicolor, and cutaneous candidiasis), availability in several formulations (cream, lotion, topical solution), pediatric labeling in children older than 2 years of age, and high utilization in the MHS (#1 in utilization at the MTFs at 11,000 Rxs/month). Nystatin is also recommended for BCF selection due to its availability in several formulations (cream, ointment, powder), widespread usage for cutaneous candidiasis, rapid symptomatic relief, popularity of the powder dosage form, and high utilization (#3 in MTFS at 4,500 Rxs/month). Ketoconazole is #2 in MTF utilization, the CMA revealed it to be less cost effective than clotrimazole, and there is no therapeutic rationale to include two azoles on the BCF. Based on the relative clinical and cost effectiveness analyses, the P&T Committee recommended placing clotrimazole and nystatin on the BCF. MTFs can add additional UF topical antifungals to their local formularies if needed to meet the needs of their specific patient populations.

Conclusion: The P&T Committee concurred with the recommendation to place clotrimazole and nystatin on the BCF.

COMMITTEE ACTION: The P&T Committee voted (12 for, 0 opposed, 1 abstained) to recommend clotrimazole and nystatin as the BCF agents.

16 February 2005

DECISION PAPER:

FEBRUARY 2005 DoD PHARMACY AND THERAPEUTICS COMMITTEE RECOMMENDATIONS

1. CONVENING

2. ATTENDANCE

3. REVIEW MINUTES OF LAST MEETING

4. INTERIM DECISIONS/ADMINISTRATIVE ISSUES

5. ITEMS FOR INFORMATION

6. DRUG REVIEW PROCESS

Implementation of the Uniform Formulary (UF) entails a wide variety of actions, with various levels of involvement of the DoD Pharmacy and Therapeutics (P&T) Committee, the Beneficiary Advisory Panel (BAP), and the Director, TRICARE Management Activity (TMA). However, not all of these actions require comment by the BAP, or recommendations or action by the P&T Committee or final decision by the Director, TMA, before they can be implemented. The P&T Committee developed a comprehensive list of the functions associated with formulary management and categorized each into one of three decision process categories, depending on the level of involvement for the P&T Committee, BAP, and/or Director, TMA.

COMMITTEE ACTION: Functions/actions of the Committee were reviewed and categorized according to the following processes: administrative functions (day-to-day maintenance not requiring DoD P&T Committee review), formulary recommendations requiring DoD P&T Committee review and approval by the Director, TMA, and formulary changes requiring DoD P&T Committee review and approval of the Committee's recommendations by the Director, TMA, after considering comments from the BAP. (See paragraph 6 and Table 1 on pages 13-14 of P&T Committee minutes.)

Recommendation: The Committee recommended approval of functions and decision categories as described.

*Director, TMA, Decision***:** □ Approved □ Disapproved

□ Approved, but modified as follows

7. PRIOR AUTHORIZATIONS

The P&T Committee reviewed existing prior authorizations (PAs) and recommended rules for agents that are approved by the Food and Drug Administration (FDA) between Committee meetings that are in therapeutic classes for which PAs already exist.

COMMITTEE ACTION: The Committee discussed how to apply existing drug class PAs to newly FDA-approved drugs in within the class. (See paragraph 7 on pages 14-15 of P&T Committee minutes.)

The Committee recommended the following:

- Phosphodiesterase-5 (PDE-5) inhibitors – Any new PDE-5 inhibitor that may become available for the treatment of erectile dysfunction will be subject to the same PA as the existing agents.

*Director, TMA, Decision***:** □ Approved □ Disapproved

□ Approved, but modified as follows:

- Injectable gonadotropins – Any new injectable gonadotropin that may become available for infertility treatment will be subject to the same PA as the existing agents.

*Director, TMA, Decision***:** □ Approved □ Disapproved

□ Approved, but modified as follows:

- Antifungals for onychomycosis – Any new oral or topical antifungal that may become available for the treatment of onychomycosis will be subject to the same PA as the exiting agents, with course of therapy limits set based on recommended dosing.

*Director, TMA, Decision***:** □ Approved □ Disapproved

□ Approved, but modified as follows:

- Growth hormone agents – Any new growth hormone agent that may become available will be subject to the same PA as the existing agents.

*Director, TMA, Decision***:** □ Approved □ Disapproved

□ Approved, but modified as follows:

8. QUANTITY LIMITS

The P&T Committee reviewed all current quantity limits (QLs) with the intention to recommend any necessary additions, deletions, or changes, and to formulate and recommend rules for those QLs that apply to groups of medications, including new medications or formulations as soon as they become available. The P&T Committee's goal is to ensure a consistent benefit and avoid circumstances under which a newly approved medication, very similar to another medication for which a QL exists, is on the UF for several months of unrestricted use before a QL can be applied. The PEC would report changes to QLs following these general rules at the next scheduled DoD P&T Committee meeting.

A. COMMITTEE ACTION: The P&T Committee recommended the establishment of general QL rules for the following groups of medications (see paragraph 8 on page 15-16 of P&T Committee minutes and Appendix A for the rationale):

- Medications for the treatment of erectile dysfunction (PDE-5 inhibitors and injectable/intraurethral prostaglandins)

*Director, TMA, Decision***:** □ Approved □ Disapproved
□ Approved, but modified as follows:

- 5-HT3 receptor antagonists (antiemetic medications)

*Director, TMA, Decision***:** □ Approved □ Disapproved
□ Approved, but modified as follows:

- 5HT-1 receptor agonists ("triptans") for the treatment of migraine

*Director, TMA, Decision***:** □ Approved □ Disapproved
□ Approved, but modified as follows:

- Dihydroergotamine products for the treatment of migraine

*Director, TMA, Decision***:** □ Approved □ Disapproved
□ Approved, but modified as follows:

- Fertility agents (injectable gonadotropins)

*Director, TMA, Decision***:** □ Approved □ Disapproved
□ Approved, but modified as follows:

- Nasal inhalers for the treatment of allergic and nonallergic rhinitis

*Director, TMA, Decision***:** □ Approved □ Disapproved
□ Approved, but modified as follows:

- Oral inhalers and inhalant solutions for the treatment of asthma, chronic obstructive lung disease, or allergies

*Director, TMA, Decision***:** □ Approved □ Disapproved
□ Approved, but modified as follows:

- Tramadol-containing products

*Director, TMA, Decision***:** □ Approved □ Disapproved
□ Approved, but modified as follows

B. COMMITTEE ACTION*:* The P&T Committee recommended the following specific changes to QLs (see paragraph 8 on page 16 of P&T Committee minutes and Appendix A for the rationale):

- Dihydroergotamine nasal spray (Migranal) – change to 16 amps per 30 days; 48 amps per 90 days)

*Director, TMA, Decision***:** □ Approved □ Disapproved
□ Approved, but modified as follows:

C. COMMITTEE ACTION*:* The Committee recommended the establishment of QLs for newly-approved agents: (See paragraph 8 on page 16 of P&T Committee minutes and Appendix A for the rationale):

- Azelastine nasal spray (Astelin) – 1 bottle per 30 days or 3 bottles per 90 days

*Director, TMA, Decision***:** □ Approved □ Disapproved
□ Approved, but modified as follows:

- Tazarotene (Tazorac) cream – 60 gm (1 large tube) per 30 days; 180 gm per 90 days

*Director, TMA, Decision***:** □ Approved □ Disapproved
□ Approved, but modified as follows

D. COMMITTEE ACTION*:* The P&T Committee recommended the deletion of QLs: (See paragraph 8 on pages 16-17 of P&T Committee minutes and Appendix A for the rationale):

- Azithromycin (Zithromax) 250- and 600-mg tablets

*Director, TMA, Decision***:** □ Approved □ Disapproved
□ Approved, but modified as follows:

- Dornase alpha inhalation solution (Pulmozyme)

*Director, TMA, Decision***:** □ Approved □ Disapproved
□ Approved, but modified as follows

- Fluconazole (Diflucan, generics) 150 mg tablets

*Director, TMA, Decision***:** □ Approved □ Disapproved
□ Approved, but modified as follows:

- Imiquimod cream (Aldara)

*Director, TMA, Decision***:** □ Approved □ Disapproved
□ Approved, but modified as follows

- Testosterone buccal system (Striant)

*Director, TMA, Decision***:** □ Approved □ Disapproved
□ Approved, but modified as follows

9. REVIEW OF RECENTLY-APPROVED DRUGS

The P&T Committee was briefed on agents who had been approved by the FDA and introduced into the U.S. market since the July 2004 meeting. None of the new medications fall into drug classes already reviewed by the P&T Committee; therefore, the P&T Committee deferred UF consideration until the applicable drug class reviews are completed.

COMMITTEE ACTION*:* The Committee recommended quantity limits for the following products (see paragraph 9 on page 17 of P&T Committee minutes and Appendix B for the rationale):

- Erlotinib tabs (Tarceva) – limit of 30 day supply in retail, 45 day supply in TRICARE Mail Order Pharmacy (TMOP) Program, up to 45 day supply in MTFs. No multiple fills for multiple co-pays in retail and TMOP

*Director, TMA, Decision***:** □ Approved □ Disapproved
□ Approved, but modified as follows:

- Gemifloxacin tablets (Factive) – limit of 7 days supply per 30 days in retail, TMOP and MTFs

*Director, TMA, Decision***:** □ Approved □ Disapproved
□ Approved, but modified as follows:

10. BASIC CORE FORMULARY (BCF) ISSUES

The DoD P&T Committee reviewed the relative clinical and cost effectiveness of timolol maleate ophthalmic solutions and gels, which had previously been placed on the BCF. MTFs are advised that the BCF listing for timolol maleate products relates to the product for which DoD has a sole source contract, and does not include the Istalol brand of timolol maleate ophthalmic solution.

11. ANGIOTENSIN RECEPTOR BLOCKER (ARB) DRUG CLASS REVIEW

The P&T Committee evaluated the relative clinical effectiveness of the seven angiotensin receptor blockers (ARBs): losartan (Cozaar), irbesartan (Avapro), valsartan (Diovan), candesartan (Atacand), telmisartan (Micardis), eprosartan (Teveten), olmesartan (Benicar), and included their respective combinations with hydrochlorothiazide. There has been an increase in the use of ARBs over the past five years, and the class is now in the top 10 of Military Health System (MHS) drug class expenditures.

A. COMMITTEE ACTION: The Committee concluded that (1) all seven ARBs have similar relative clinical effectiveness for treating hypertension; (2) that candesartan and valsartan have similar relative clinical effectiveness for treating chronic heart failure; (3) that losartan and irbesartan have similar relative clinical effectiveness for treating Type 2 diabetics with nephropathy; and (4) that all seven ARBs have similar safety and tolerability profiles. Valsartan, candesartan, losartan and irbesartan have higher clinical utility (overall clinical usefulness) relative to the three ARBs that are indicated solely for treating hypertension (telmisartan, eprosartan, and olmesartan). (See paragraph 11 A. on pages 18-19 of P&T Committee minutes.) The P&T Committee concluded that eprosartan was not cost-effective relative to the other ARBs for treating hypertension. Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of the ARBs, and other relevant factors, the P&T Committee voted to recommend formulary status for candesartan, irbesartan, losartan, olmesartan, telmisartan, and valsartan, and non-formulary status for eprosartan under the UF. (See paragraph 11 B. on page 20 of P&T Committee minutes.) Under 32 C.F.R. 199.21(g)(3), no pharmaceutical agent may be designated as non-formulary on the UF unless preceded by such recommendation by the P&T Committee.

*Director, TMA, Decision***:** □ Approved □ Disapproved

□ Approved, but modified as follows:

B. COMMITTEE ACTION: Based on the clinical evaluation of eprosartan, and the conditions for establishing medical necessity for a non-formulary medication provided for in the Uniform Formulary rule, the P&T Committee recommended medical necessity criteria for eprosartan. (See paragraph 11 C. on pages 20-21 of P&T Committee minutes for criteria.)

*Director, TMA, Decision***:** □ Approved □ Disapproved

□ Approved, but modified as follows:

C. COMMITTEE ACTION: Because relatively few patients are receiving eprosartan at any MHS pharmacy point of service (less than 1% of all patients receiving ARBs), the P&T Committee recommended an effective date of 30 days from the final decision date (the date that DoD P&T Committee minutes are signed by the Director, TMA, approving the Committee's recommendation). (See paragraph 11 D. on page 21 of P&T Committee minutes for rationale.)

*Director, TMA, Decision***:** □ Approved □ Disapproved

□ Approved, but modified as follows:

D. COMMITTEE ACTION: Within the MTFs, the majority of ARB usage is for treating hypertension, and not for treating chronic heart failure or Type 2 diabetic nephropathy. Although valsartan, candesartan, irbesartan, and losartan have additional indications, which are of importance in the UF at the MTF setting, selecting one BCF ARB with a sole indication for hypertension is sufficient to meet the needs of the majority of patients. Based on the relative clinical and cost effectiveness analyses, the P&T Committee recommended placing telmisartan on the BCF. MTFs can add additional ARBs to their local formularies if needed to meet the needs of their specific patient populations. (See paragraph 11 E. on pages 21-22 of P&T Committee minutes for rationale.)

*Director, TMA, Decision***:** □ Approved □ Disapproved

□ Approved, but modified as follows:

12. PROTON PUMP INHIBITOR (PPI) DRUG CLASS REVIEW

The P&T Committee evaluated the relative clinical effectiveness of all the FDA-approved proton pump inhibitors (PPIs) available in the US: omeprazole (Prilosec, Zegerid & generics), lansoprazole (Prevacid), rabeprazole (Aciphex), pantoprazole (Protonix) and esomeprazole (Nexium). PPIs are among the top 10 MHS drug class expenditures.

A. COMMITTEE ACTION*:* The P&T Committee concluded that all PPIs have similar relative clinical effectiveness for treating gastroesophageal reflux disease (GERD) and peptic ulcer disease (PUD). All five PPIs have similar safety and tolerability profiles. (See paragraph 12 A. on paged 22-23 of P&T Committee minutes for the rationale). The P&T Committee concluded that esomeprazole was not cost effective relative to the other PPIs. Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of the PPIs and other relevant factors, the P&T Committee voted to recommend non-formulary status for esomeprazole, with rabeprazole, lansoprazole, and pantoprazole maintaining formulary status with a formulary cost share, and omeprazole maintaining formulary status with a generic cost share. (See paragraph 12 B. on page 23 of P&T Committee minutes for the rationale.) Under 32 C.F.R. 199.21(g)(3), no pharmaceutical

agent may be designated as non-formulary on the UF unless preceded by such recommendation by the P&T Committee.

*Director, TMA, Decision***:** □ Approved □ Disapproved

□ Approved, but modified as follows:

B. COMMITTEE ACTION: Based on the clinical evaluation of esomeprazole, and the conditions for establishing medical necessity for a non-formulary medication provided for in the Uniform Formulary rule, the P&T Committee recommended medical necessity criteria for esomeprazole. (See paragraph 12 C. on pages 23-24 of P&T Committee minutes for the criteria.)

*Director, TMA, Decision***:** □ Approved □ Disapproved

□ Approved, but modified as follows:

C. COMMITTEE ACTION: Based on the substantial number of patients currently receiving esomeprazole from one of the three MHS pharmacy points of service (138,739 patients, or 13.4 % of all patients receiving PPIs), the P&T Committee recommended an implementation date of 90 days from the final decision date (the date that DoD P&T Committee minutes are signed by the Director, TMA, approving the Committee's recommendation). (See paragraph 12 D. on page 24 of P&T Committee minutes for the rationale.)

*Director, TMA, Decision***:** □ Approved □ Disapproved

□ Approved, but modified as follows:

D. COMMITTEE ACTION: Based on the relative clinical and cost-effectiveness, the P&T Committee recommended placing omeprazole (generic) and rabeprazole (Aciphex) on the BCF. However, omeprazole suspension (Zegerid) and Prilosec 40 mg were excluded from the BCF, because they were less cost-effective than the generic omeprazole. (See paragraph 12 E. on pages 24-25 of P&T Committee minutes for rationale.)

*Director, TMA, Decision***:** □ Approved □ Disapproved

□ Approved, but modified as follows:

DECISION ON RECOMMENDATIONS

Director, TMA, decisions are as annotated above.

_____

William Winkenwerder, Jr., M.D.
Date:

Department of Defense
Pharmacy and Therapeutics Committee Minutes

16 February 2005

1. CONVENING

The DoD P&T Committee convened at 0800 hours on 15 and 16 February 2005 at the DoD Pharmacoeconomic Center, Fort Sam Houston, Texas.

2. ATTENDANCE

A. Voting Members Present

CAPT Patricia Buss, MC	DoD P& T Committee Chair
CDR Mark Richerson, MSC	DoD P& T Committee Recorder
Col James Young, BSC	Director, DoD Pharmacy Programs, TMA
Capt Michael Proffitt, MC (present Feb 15th only)	Air Force, OB/GYN Physician
Maj Nick Conger, MC	Air Force, Internal Medicine Physician
Maj Charlene Reith, BSC (for Col Phil Samples, BSC)	Air Force, Pharmacy Officer
CDR William Hall, MC	Navy, Internal Medicine Physician
LCDR Suzanne Haney, MC	Navy, Pediatrics Physician
CDR Brian Alexander, MC	Navy, Physician at Large
CDR Ted Briski, MSC (for LT Joseph Lawrence, MSC)	Navy, Pharmacy Officer
COL Doreen Lounsbery, MC	Army, Internal Medicine Physician
MAJ Roger Brockbank, MC	Army, Family Practice Physician
COL Joel Schmidt, MC	Army, Physician at Large
COL Isiah Harper, MS	Army, Pharmacy Officer
CDR Mary Fong (for CDR Patrick Marshall)	Coast Guard, Pharmacy Officer
LTC Donald DeGroff, MS	Contracting Officer Representative, TMOP
CDR Jill Pettit, MSC	Contracting Officer Representative, TRRx
Joe Canzolino	Department of Veterans Affairs

B. Voting Members Absent

Maj Brian Crownover, MC	Air Force, Physician at Large

C. Non-Voting Members Present

Howard Altschwager	Deputy General Counsel, TMA
Martha Taft	Resource Management Directorate, TMA
Capt Peter Trang, BSC	Defense Supply Center Philadelphia

D. Non-Voting Members Absent

COL Kent Maneval, MS	Joint Readiness Clinical Advisory Board

E. Others Present

CAPT Betsy Nolan, MSC	Navy Pharmacy Specialty Leader
CDR Bill Blanche, MSC	Future Navy Pharmacy Specialty Leader
CDR Denise Graham, MSC	DoD Pharmacoeconomic Center
CAPT Don Nichols, MC	DoD Pharmacoeconomic Center
Lt Col Dave Bennett, BSC	DoD Pharmacoeconomic Center
Lt Col Barb Roach, MC	DoD Pharmacoeconomic Center
Maj Wade Tiller, BSC	DoD Pharmacoeconomic Center
CPT Jill Dacus, MC	DoD Pharmacoeconomic Center
Shana Trice	DoD Pharmacoeconomic Center
Dave Bretzke	DoD Pharmacoeconomic Center
Angela Allerman	DoD Pharmacoeconomic Center
Eugene Moore	DoD Pharmacoeconomic Center
Julie Liss	DoD Pharmacoeconomic Center
Elizabeth Hearin	DoD Pharmacoeconomic Center
Dave Flowers	DoD Pharmacoeconomic Center
Col Nancy Misel, BSC	IMA, DoD Pharmacoeconomic Center
Todd Semla	Department of Veterans Affairs

3. REVIEW MINUTES OF LAST MEETING

Dr. William Winkenwerder, Jr., M.D. approved the minutes of the first meeting of the restructured DoD Pharmacy and Therapeutics (P&T) Committee held July 2004 on October 5, 2004.

4. INTERIM DECISIONS/ADMINISTRATIVE ISSUES

None.

5. ITEMS FOR INFORMATION

TRICARE Management Activity (TMA) and DoD Pharmacoeconomic Center (PEC) staff members briefed the P&T Committee on the following:

A. The TRICARE Pharmacy Benefit Program Formulary Management Policy (HA Policy 04-032) was signed by Dr. Winkenwerder on December 22, 2004. This new HA Policy addresses how formulary management in the Military Health System (MHS) is accomplished by the DoD P&T Committee through the Uniform Formulary (UF), the Basic Core Formulary (BCF), and the Extended Core Formulary (ECF). Formulary

management by the Services and individual Military Treatment Facilities (MTFs) is limited to the circumstances described in this policy.

B. Quantity Limits, Prior Authorizations, and Medical Necessity Criteria – 10 U.S.C. § 1074g requires the establishment of an effective, efficient, integrated pharmacy benefit program under chapter 55 of title 10, United States Code, which applies to MTFs as well as to the purchased care system. The DoD P&T Committee makes recommendations to the Director, TMA, not only on formulary/non-formulary status for pharmaceutical agents in a class, but also on prior authorizations, quantity limits, and medical necessity criteria. Therefore, prior authorizations, quantity limits, and medical necessity criteria established by the DoD P&T Committee will apply to all three points of service.

C. Review of Medications for the Uniform Formulary – The Director, TMA, directed the implementation of the UF as a phased-in approach, one class at a time. Operating rules of the UF will only be applicable for those drug classes already evaluated by the DoD P&T Committee. The P&T Committee will meet quarterly to review new and existing drugs and/or drug classes and recommend pharmaceutical agents for inclusion or exclusion on the UF based on their relative clinical and cost effectiveness.

D. Formulary Resources for Beneficiaries – The TRICARE Pharmacy website (www.tricare.osd.mil/pharmacy) was recently restructured to provide additional information to DoD beneficiaries regarding the pharmacy benefit. The site now provides general formulary information, information about eligibility and claims, MTF and retail pharmacy locators, and a Formulary Search Tool.

The Formulary Search Tool enables beneficiaries to determine cost share, availability, prior authorization status, and quantity limits for specific medications at retail network pharmacies and the mail order pharmacy. A particular strength is the fact that the database searched by the tool is not limited to medications available through the pharmacy benefit, allowing a beneficiary to determine, for example, that a particular medication is over-the-counter, not covered by TRICARE, or covered by TRICARE but not considered to be part of the pharmacy benefit. The Formulary Search Tool also designates whether medications are listed on the BCF and provides information on whether generic equivalents are available for specific medications.

E. High Dollar Drugs – The introduction of clinically effective but costly new therapies can have a large, unexpected, negative impact on MTF pharmacy budgets. To complicate the issue, many of these new agents are biotech agents administered in inpatient or office/clinic settings, and therefore covered under the TRICARE medical benefit rather than the pharmacy benefit. Unfortunately, there is no uniform mechanism or policy in place across the services, or even across MTFs within a service, for dealing with this type of budget impact. Shifting use of the product to the network to be covered under the medical benefit will minimize pharmacy budget impact but increase the cost to the facility, since it will be billed for the network care. The P&T Committee concluded that attention needs to be given to formulating a uniform policy for handling high cost medications within the direct care system.

Col Nancy Misel, BSC, USAF, Director of the Air Force High Dollar Drug Program, briefed the P&T Committee on the program used by the Air Force to address this issue. Initiated at Wright-Patterson AFB in 1995, the High Dollar program is a centrally funded air staff program that provides high cost medications, on an individual patient basis, to

Air Force MTFs at no cost to the MTF. The criteria for drugs to be included in the program are predominantly based on cost. Other factors that would place a drug within the scope of the program include drugs with restricted distribution requirements that require administrative actions to procure or dispense (e.g., thalidomide) and drugs with low use and/or narrow therapeutic ranges. The program permits facilities to appropriately manage patient care without cost shifting to another venue or adversely impacting the local budget. It also ensures that funds for these medications do not need to be distributed to multiple locations and that access to medications is not interrupted when patients relocate or deploy.

Approximately 100 medications are being supplied under the current program guidelines, with approximately 75% of those drugs being new to the market since program implementation. The estimated expenditure for FY 05 is $25M. Advantages of the centralized program include 100% inventory control, minimization of MTF inventory requirements, the ability for a MTF to return unused drugs for future use at another MTF, expenditures which are easily attributable to user facilities, and a source for clinical oversight and support, as MTF expertise with these drugs may be limited. In addition, the program utilizes TRICARE quantity limits and prior authorization criteria to ensure an even playing field with the retail network and TRICARE Mail Order Pharmacy (TMOP) Program.

Col Misel noted that the Air Force program could be either the core for an expanded centrally-funded program, or easily exported to the other services, and is one option for dealing with the impact of costly therapies in the direct care system.

6. DRUG REVIEW PROCESS

Under 10 U.S.C. § 1074g and 32 C.F.R. 199.21, the DoD P&T Committee is responsible for developing the UF. Recommendations to the Director, TMA, on formulary status, preauthorizations, and the effective date for a drug's change from formulary to non-formulary status must be reviewed by the Beneficiary Advisory Panel (BAP) before the Director may make a final decision. Additionally, the P&T Committee may make recommendations on quantity limits, medical necessity criteria for non-formulary pharmaceutical agents, and additions, deletions, or clarifications to drugs that are on the BCF and ECF. These recommendations do not require review and comment by the BAP prior to decision by the Director. Finally, there are certain administrative processes required for the day-to-day operation of the UF that do not require recommendations or action by the P&T Committee or final decision by the Director, TMA, before they can be implemented. The P&T Committee developed a comprehensive list of functions associated with formulary management and categorized each in one of these three decision process categories which are outlined in Table 1.

Table 1: Processes and Recommendation/Approval Authorities

Process	Function
Administrative (not part of DoD P&T Committee process, Beneficiary Advisory Panel (BAP) comments not required, Director, TMA, approval not required) Responsible parties include: TRICARE Mail Order Pharmacy and TRICARE Retail Pharmacy Contracting Officer Representatives (TMOP and TRRx CORs), TMA Pharmacy Program, TMA Office of General Counsel, and Pharmacoeconomic Center (PEC) staff	▪ Identification of new FDA-approved medications, formulations, strengths, package sizes, etc. ▪ If situation unclear, determination as to whether a new FDA-approved medication is covered by TRICARE ▪ If situation unclear, determination as to whether a new FDA-approved medication is part of the pharmacy benefit ▪ If situation unclear, determination as to whether a new FDA-approved medication is suitable for dispensing through the TRICARE Mail Order Pharmacy (TMOP) ▪ Calculating and implementing quantity limits if already established through the DoD P&T Committee process for a given medication or class of medications ▪ Making changes to quantity limits as needed based on non-clinical factors such as changes to packaging (e.g., medication previously available in boxes of 5 now only available packaged in boxes of 8) ▪ Establishing adjudication edits (PDTS limitations which are set well above the clinical maximum and are intended to prevent entry errors [e.g., entering a quantity of 17 for a 17-gram inhaler for which the actual unit of measure is 1 inhaler] or are intended to limit diversion) ▪ Implementing prior authorization requirements if already established through the DoD P&T Committee process for a given medication or class of medications ▪ Making minor changes to prior authorization forms NOT involving changes to underlying criteria, such as correcting contact information or rewording clinical questions ▪ Making changes to PA criteria, medical necessity criteria, quantity limits and any associated documents to accommodate new FDA-approved indications or respond to changes in FDA-recommended safety limitations (changes will be reviewed by DoD P&T Committee at next meeting) ▪ Removing medications withdrawn from the U.S. market from Basic Core Formulary (BCF) or Extended Core Formulary (ECF) listings and other documents ▪ Providing clarifications to existing listings on the BCF or ECF to specify specific brands/manufacturers when a joint DoD/VA mandatory source generic contract is awarded for a given product (i.e., clarifying an existing listing for “atenolol” to include the contractual requirement to use a specific manufacturer’s products) ▪ As necessary to accomplish functions above: for example, making changes to PDTS coding for TMOP & TRRx, communicating status of medications as part of the pharmacy or medical benefit to Managed Care Support Contractors (MCSCs), making changes to the TMA Pharmacy website and the TRICARE Formulary Search Tool, and making changes to BCF and ECF listings on the PEC website.
Approval by Director, TMA, required based on DoD P&T Committee recommendations and BAP comments	▪ Classification of a medication as non-formulary on the Uniform Formulary (UF), and implementation plan (including effective date) ▪ Establishment of prior authorization requirement for a medication or class of medications, summary/outline of prior authorization criteria, and implementation plan (including effective date) ▪ Changes to existing prior authorization and medical necessity criteria (e.g., due to the availability of new efficacy or safety data) ▪ Discontinuation of prior authorization requirements
Approval by Director, TMA, required based on DoD P&T Committee recommendations (not required to be submitted to BAP for comments)	▪ Establishment of quantity limits for a medication or class of medications; deletion of existing quantity limits; changes to existing quantity limits based on clinical factors (e.g., new clinical data or dosing regimens) ▪ Establishment of medical necessity criteria for non-formulary agents ▪ Addition, deletion of medications listed on the Basic Core Formulary (BCF) or Extended Core Formulary (ECF)

7. PRIOR AUTHORIZATIONS

The P&T Committee reviewed existing prior authorizations and recommended rules that can be applied immediately to drugs approved by the Food and Drug Administration (FDA) between Committee meetings, when the drug belongs to a drug class for which prior

authorizations already exist. The recommended rules would provide a consistent benefit and avoid circumstances under which a newly approved medication, very similar to another medication for which a prior authorization exists, is on the UF for several months of unrestricted use before a prior authorization can be applied. The PEC would report changes to prior authorizations following these general rules at the next scheduled DoD P&T Committee meeting.

COMMITTEE ACTION: The P&T Committee made the following recommendations regarding rules that can be applied immediately to drugs approved by the FDA between P&T Committee meetings:

- *Phosphodiesterase-5* (*PDE-5) inhibitors* – Any new PDE-5 inhibitor that may become available for the treatment of erectile dysfunction will be subject to the same prior authorization as the existing agents – 14 for, 0 opposed, 1 abstention, 3 absent.
- *Injectable gonadotropins* – Any new injectable gonadotropin that may become available for infertility treatment will be subject to the same prior authorization as the existing agents – 15 for, 0 opposed, 1 abstention, 2 absent.
- *Antifungals for onychomycosis* - Any new oral or topical antifungal that may become available for the treatment of onychomycosis will be subject to the same prior authorization as the existing agents, with course of therapy limits set based on recommended dosing – 15 for, 0 opposed, 1 abstain, 2 absent.
- *Growth hormone agents* - Any new growth hormone agent that may become available will be subject to the same prior authorization as the existing agents – 15 for, 0 opposed, 1 abstention, 2 absent.

8. REVIEW OF QUANTITY LIMITS

The P&T Committee reviewed all current quantity limits with two goals: 1) to recommend any necessary additions, deletions, or changes; and 2) to formulate and recommend rules for those quantity limits that apply to groups of medications (e.g., oral inhalers, “triptans,” PDE-5 inhibitors), including new medications or formulations as soon as they become available.

The quantity limits rules formulated by the P&T Committee for groups of medications include a number of factors which must be considered: the maximum quantity typically required by patients (usually based on product labeling); FDA-recommended safety recommendations in product labeling or other safety concerns; commercial package sizes available, and whether a given package size is typically dispensed to patients as a unit; and the operational requirement that 90-day limits should be three times the 30-day limits whenever possible. It should be noted that quantity limits have several operational safeguards in place to accommodate individual patient needs, including an exception process for patients with a valid clinical need for greater quantities than provided for by the quantity limits, and provisions to allow for dose changes, vacation supplies, and deployment supplies.

The P&T Committee noted that quantity limits apply to MTFs, as well as to the TMOP, and the retail pharmacy network. Network retail pharmacies typically dispense up to a 30-day supply of medications, although patients may obtain up to a 90-day supply of most medications by paying the appropriate multiple cost shares. The TMOP dispenses up to a 90-day supply. MTFs make local decisions as to days supply dispensed, but typically dispense a 90-day supply of chronic medications. Accordingly, quantity limits are listed in these

minutes as amounts per 30 or 90 days whenever possible. It is anticipated that MTFs will most often utilize the quantity limits that apply to the TMOP.

A. Quantity Limit Rules: The P&T Committee recommended the establishment of quantity limit rules that apply to groups of medications, including new medications or formulations as soon as they become available. This will provide a consistent benefit and avoid circumstances under which quantity limits exist for very similar medications, but which are applied to newly-approved medications of the same type only after several months of unrestricted use. The PEC would report changes in quantity limits following these general rules at the next scheduled DoD P&T Committee meeting.

COMMITTEE ACTION: The P&T Committee recommended the establishment of quantity limit rules for the following groups of medications. Details may be found in Appendix A.

- Medications for the treatment of erectile dysfunction (PDE-5 inhibitors and injectable/intraurethral prostaglandins) – 16 for, 1 opposed, 1 abstention
- 5-hydroxytryptamine (serotonin) receptor 3 (5-HT3) antagonists (antiemetic medications) – 17 for, 0 opposed, 1 abstention
- 5-hydroxytryptamine-1 (5HT-1) receptor agonists ("triptans") for the treatment of migraine- 17 for, 0 opposed, 1 abstention
- Dihydroergotamine products for the treatment of migraine – 17 for, 0 opposed, 1 abstention
- Fertility agents (injectable gonadotropins) – 17 for, 0 opposed, 1 abstention
- Nasal inhalers for the treatment of allergic and nonallergic rhinitis – 17 for, 0 opposed, 1 abstention
- Oral inhalers and inhalant solutions for the treatment of asthma, chronic obstructive lung disease, or allergies – 17 for, 0 opposed, 1 abstention
- Tramadol-containing products – 17 for, 0 opposed, 1 abstention

B. Quantity Limit Changes: The P&T Committee recommended specific changes to QLs for one product.

COMMITTEE ACTION: The P&T Committee recommended a reduction in QLs for this product. Details may be found in Appendix A.

- Dihydroergotamine nasal spray (Migranal) – change to 16 amps per 30 days; 48 amps per 90 days – 17 for, 0 opposed, 1 abstention

C. Quantity Limit Establishment: The P&T Committee recommended establishment of QLs for several drugs.

COMMITTEE ACTION: The P&T Committee recommended establishment of QLs for two drugs, both of which are very similar to medications which already have QLs. Details may be found in Appendix A.

- Azelastine nasal spray (Astelin) – 1 bottle per 30 days or 3 bottles per 90 days – 17 for, 0 opposed, 1 abstention
- Tazarotene (Tazorac) cream – 60 gm (1 large tube) per 30 days; 180 gm per 90 days – 17 for, 0 opposed, 1 abstention

D. Quantity Limit Deletion: The P&T Committee recommended deletion of QLs for several drugs.

COMMITTEE ACTION: The P&T Committee recommended deletion of QLs for five drugs. Details may be found in Appendix A.

- Azithromycin (Zithromax) 250- and 600-mg tablets – 17 for, 0 opposed, 1 abstention
- Dornase alpha inhalation solution (Pulmozyme) – 17 for, 0 opposed, 1 abstention
- Fluconazole (Diflucan, generics) 150 mg tablets – 17 for, 0 opposed, 1 abstention
- Imiquimod cream (Aldara) – 13 for, 4 opposed, 1 abstention
- Testosterone buccal system (Striant) – 17 for, 0 opposed, 1 abstention

9. REVIEW OF RECENTLY-APPROVED AGENTS

The PEC presented clinical information on 13 new medications approved by the FDA and introduced to the U.S. market since the July 2004 meeting (see Appendix A). Since none of the new medications fall into drug classes already reviewed by the P&T Committee, UF consideration was deferred until drug class reviews are completed. The P&T Committee did not recommend prior authorization requirements for any of the new drugs.

The PEC also informed the P&T Committee of two newly approved medications that do not fall under the outpatient pharmacy benefit, but may substantially impact MTF pharmacy budgets. These medications are natalizumab (Tysabri), an intravenous infusion for the treatment of multiple sclerosis, and pegaptanib (Macugen), an intravitreous injection for the treatment of neovascular (wet) age-related macular degeneration. [Note: as of February 28, 2005, distribution of natalizumab was suspended by the manufacturer due to two serious adverse events, including one fatal case and one possible case of progressive multifocal leukoencephalopathy.]

COMMITTEE ACTION

The P&T Committee recommended quantity limits for the following recently approved products:

- Erlotinib tabs (Tarceva) – limit of 30 day supply in retail, 45 day supply in TMOP, up to 45 day supply in MTFs. No multiple fills for multiple cost shares in retail and TMOP – 16 for, 0 opposed, 1 abstention, 1 absent at time of vote.
- Gemifloxacin tablets (Factive) – limit of 7 days supply per 30 days in retail, TMOP, and MTFs - 16 for, 0 opposed, 1 abstention, 1 absent at time of vote.

10. BASIC CORE FORMULARY (BCF) ISSUES

The BCF is a subset of the UF and is a mandatory component of all MTF pharmacy formularies. The DoD P&T Committee previously placed timolol maleate ophthalmic solution and gel on the BCF. Timolol maleate ophthalmic solution 0.25% and 0.5%, administered twice daily, are available with a contract price of $1.52 per 5 ml. Timolol maleate ophthalmic gel 0.25% and 0.5%, administered once daily, are available at the contract price of $10.57 and $12.81 per 5 ml for the 0.25% and 0.5%, respectively.

Timolol maleate 0.5% ophthalmic solution (Istalol) was approved by the FDA in June 2004, and became available on the market in January 2005. Istalol contains potassium sorbate, which is stated to enhance the bioavailability of the drug in solution, allowing for once daily administration. Istalol has similar efficacy, safety, and tolerability compared to timolol maleate products currently on the BCF, but costs much more, with a FSS price of $24.33 per 5 ml. The FDA has given Istalol a Therapeutic Equivalent Code of BT, meaning that it is a topical product that has acceptable clinical performance, but is not bioequivalent to other pharmaceutically equivalent products or lacks sufficient evidence of bioequivalence.

MTFs are advised that the BCF listing for timolol maleate products relates to the product for which DoD has a sole source contract, and does not include the Istalol brand of timolol maleate ophthalmic solution.

11. ANGIOTENSIN RECEPTOR BLOCKERS (ARBs) DRUG CLASS REVIEW

A. ARB Uniform Formulary Relative Clinical Effectiveness: The P&T Committee evaluated the relative clinical effectiveness of the seven ARBs marketed in the U.S. by considering information regarding their safety, effectiveness, and clinical outcome. The ARB therapeutic class was defined as losartan (Cozaar), irbesartan (Avapro), valsartan (Diovan), candesartan (Atacand), telmisartan (Micardis), eprosartan (Teveten), olmesartan (Benicar) and their respective combinations with hydrochlorothiazide. The clinical review included consideration of pertinent information from a variety of sources determined by the P&T Committee to be relevant and reliable, including but not limited to sources of information listed in 32 C.F.R. 199.21(e)(1). The P&T Committee was advised that there is a statutory presumption that pharmaceutical agents in a therapeutic class are clinically effective and should be included on the Uniform Formulary unless the P&T Committee finds by a majority vote that a pharmaceutical agent does not have a significant, clinically meaningful therapeutic advantage in terms of safety, effectiveness, or clinical outcome over the other pharmaceutical agents included on the UF in that therapeutic class.

There has been an increase in the use of ARBs over the past five years, and the class is now in the top 10 of MHS drug class expenditures. The P&T Committee agreed that in the MHS, ARBs are not recommended as first-line agents for treating hypertension due to their higher cost and fewer trials supporting a mortality reduction, compared to diuretics or angiotensin converting enzyme (ACE) inhibitors. The ACE inhibitors and ARBs have similar safety concerns regarding hyperkalemia, elevations of serum creatinine, angioedema, and pregnancy category labeling. The ARBs have an incidence of cough similar to placebo. An ARB is an appropriate agent for hypertension if a patient cannot tolerate an ACE inhibitor.

1.) Efficacy for Hypertension: All seven ARBs are approved by the FDA for treating hypertension. In clinical trials, ARBs lowered systolic blood pressure by 7.5-10 mm Hg and diastolic blood pressure by 4.5 to 6.5 mm Hg, compared to placebo. The P&T Committee agreed that there is no evidence that any one ARB is more efficacious than the others for lowering blood pressure.

2). Efficacy for Chronic Heart Failure: When evaluating the ARBs for treatment of chronic heart failure, the P&T Committee agreed that evidence of a favorable effect on clinical outcomes (i.e., irreversible outcomes such as hospitalization for heart failure or death) is more important than evidence of favorable effects on physiologic outcomes (i.e., reversible outcomes that are surrogate markers of disease, such as changes in pulmonary capillary wedge pressure).

Two ARBs have clinical evidence from large, well-conducted, randomized controlled trials showing a reduction in the risk of hospitalization due to chronic heart failure, a clinically relevant outcome. Based on the results of the Val-HeFT trial, the FDA approved valsartan for use in patients with heart failure who are intolerant of ACE inhibitors. The CHARM trials with candesartan support its use in chronic heart failure, although at the time of the meeting the FDA had not yet approved candesartan for this indication. (Note: Candesartan was approved for heart failure on February

22, 2005, following the DoD P&T committee meeting). The P&T Committee agreed that there was no evidence that either valsartan or candesartan were preferable relative to the other for the treatment of chronic heart failure. Since none of the other ARBs have outcome studies showing a reduction in clinically relevant outcomes related to chronic heart failure, the P&T Committee agreed that valsartan and candesartan were preferable to the other five ARBs for the treatment of heart failure.

3.) *Efficacy for Type 2 Diabetic Nephropathy*: When evaluating the ARBs for treatment of type 2 diabetics with nephropathy, the P&T Committee agreed that evidence of a favorable effect on clinical outcomes (i.e., irreversible outcomes such as development of end stage renal disease, the need for dialysis or renal transplantation, or death) is more important than evidence of favorable effects on physiologic outcomes (i.e., reversible outcomes that are surrogate markers of disease, such as changes in the urinary albumin to creatinine ratio, urinary albumin excretion rate, or glomerular filtration rate).

Based on the results of the RENAAL and IDNT trials, the FDA has approved two ARBs, losartan and irbesartan, respectively, for treatment of diabetics who have an elevated serum creatinine and proteinuria. The P&T Committee agreed that there was no evidence that either losartan or irbesartan were preferable relative to the other for the treatment of renal nephropathy in type 2 diabetics. Since none of the other ARBs have outcome studies showing a reduction in clinically relevant outcomes related to Type 2 diabetic nephropathy, the P&T Committee agreed that losartan and irbesartan were preferable to the other five ARBs for the treatment of Type 2 diabetic nephropathy.

4.) *Safety/Tolerability:* The P&T Committee agreed that there is no evidence that any one ARB is preferable to the others with respect to safety or tolerability. These medications are generally well-tolerated, with adverse event rates for all the ARBs similar to placebo in controlled trials. The likelihood of potentially serious adverse events, including hyperkalemia, elevations of serum creatinine, and angioedema, do not appear to differ among agents. Drug interaction profiles are similar. All ARBs are pregnancy category C during the first trimester, and pregnancy category D during the second and third trimesters, based on the occurrence of fetal abnormalities with ACE inhibitors.

Conclusion: The P&T Committee concluded that (1) all seven ARBs have similar relative clinical effectiveness for treating hypertension; (2) that candesartan and valsartan have similar relative clinical effectiveness for treating chronic heart failure; (3) that losartan and irbesartan have similar relative clinical effectiveness for treating Type 2 diabetics with nephropathy; and (4) that all seven ARBs have similar safety and tolerability profiles. Valsartan, candesartan, losartan, and irbesartan have higher clinical utility (overall clinical usefulness) relative to the three ARBs that are indicated solely for treating hypertension (telmisartan, eprosartan, and olmesartan).

COMMITTEE ACTION: The P&T Committee, based upon its collective professional judgment, voted (17 for, 0 opposed, 1 abstention) to accept the conclusion that valsartan, candesartan, losartan, and irbesartan have increased clinical utility (due to their evidence for uses in addition to hypertension) relative to the three ARBs that are only indicated for treating hypertension (telmisartan, olmesartan, and eprosartan), and concluded that there is no evidence that any one ARB is more efficacious than the others for lowering blood pressure.

B. ARB Uniform Formulary Relative Cost Effectiveness: In considering the relative cost effectiveness of pharmaceutical agents in this class, the P&T Committee evaluated the costs of the agents in relation to the safety, effectiveness, and clinical outcomes of the other agents in the class. Information considered by the P&T Committee included but was not limited to sources of information listed in 32 C.F.R. 199.21(e)(2). To determine the relative cost-effectiveness of the agents within the ARB therapeutic class, two separate economic analyses were performed, a pharmacoeconomic analysis and budget impact analysis (BIA). The preceding conclusion from the P&T Committee that all seven ARBs showed similar relative clinical effectiveness for treating hypertension; that candesartan and valsartan showed similar relative clinical effectiveness for treating chronic heart failure, and that losartan and irbesartan showed similar relative clinical effectiveness for treating Type 2 diabetic nephropathy was incorporated into the models. Given the results of the clinical analysis, a series of cost-minimization analyses (CMA) were conducted which revealed: that: candesartan was more cost-effective relative to valsartan for the treatment of heart failure; irbesartan was more cost-effective relative to losartan for treatment of Type 2 diabetic nephropathy; and irbesartan was more cost-effective relative to the other ARBs for the treatment of hypertension. Moreover, it was determined that eprosartan was not cost-effective relative to the other hypertension-only ARBs (telmisartan and olmesartan).

The results of the CMA were subsequently incorporated into a BIA, which accounts for other factors and costs associated with a potential decision to recommend one or more ARBs status be changed from formulary to non-formulary such as: market share migration, cost reduction associated with non-formulary cost shares, medical necessity processing fees, and costs incurred while switching patients from non-formulary agents to formulary agents. The results of the budget impact analyses further confirmed the results from the cost minimization analyses. Eprosartan was found not to be cost-effective relative to the other hypertension ARBs.

Conclusion: The P&T Committee concluded that eprosartan was not cost-effective relative to the other ARBs for treating hypertension. Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of the ARBs, and other relevant factors, the P&T Committee recommended that eprosartan's status be changed from formulary to non-formulary, with candesartan, irbesartan, losartan, olmesartan, telmisartan, and valsartan maintaining formulary status with the formulary cost share.

COMMITTEE ACTION: The P&T Committee, based upon its collective professional judgment, voted (9 for, 7 opposed, 1 abstention, 1 absent) to recommend formulary status for candesartan, irbesartan, losartan, olmesartan, telmisartan, and valsartan, and non-formulary status for eprosartan under the UF.

C. ARB Uniform Formulary Medical Necessity Criteria: Based on the clinical evaluation of eprosartan and the conditions for establishing medical necessity for a non-formulary medication provided for in the Uniform Formulary rule, the following medical necessity criteria were proposed for eprosartan.

1.) Use of all the formulary ARBs (losartan, irbesartan, valsartan, candesartan, telmisartan, and olmesartan), is contraindicated, and the use of eprosartan is not contraindicated.

2.) The patient has experienced or is likely to experience significant adverse effects from all the formulary ARBs (losartan, irbesartan, valsartan, candesartan, telmisartan, and olmesartan) and the patient is reasonably expected to tolerate eprosartan.

3.) Use of the formulary ARBs (losartan, irbesartan, valsartan, candesartan, telmisartan, and olmesartan) resulted in therapeutic failure, and the patient is reasonably expected to respond to eprosartan.

4.) The patient has previously responded to eprosartan, and changing to a formulary ARB would incur unacceptable risk.

COMMITTEE ACTION: The P&T Committee voted (15 for, 0 opposed, 1 abstention, 2 absent) to recommend the medical necessity criteria for eprosartan listed above.

D. ARB Uniform Formulary Implementation Plan: Because relatively few patients are receiving eprosartan at any MHS pharmacy point of service (less than 1% of all patients receiving ARBs), the P&T Committee proposed a 30-day transition period for implementation of a decision by the Director, TMA, to classify eprosartan as non-formulary on the UF. Prior to the P&T Committee meeting, the Government had solicited a request for blanket purchase agreement (BPA) price quotes from manufacturers. One manufacturer subsequently filed a protest concerning this class with the Government Accountability Office (GAO). Any decision by the Director, TMA, concerning this class, including an implementation plan, may proceed; however, no award of a BPA, based on these quotes will occur until after the GAO has issued a ruling on the protest. The TMA and PEC web sites will notify all interested parties when GAO has ruled on the protest, and what subsequent decisions have been made.

MTFs are not allowed to have non-formulary pharmaceutical agents on their local formularies. MTFs will be able to fill non-formulary requests for non-formulary agents only if both of the following conditions are met: 1) the prescription is written by a MTF provider, and 2) the beneficiary and/or his or her provider has established medical necessity for the agent. MTFs may (but are not required to) fill a non-formulary prescription written by a non-MTF provider to whom the patient was referred as long as medical necessity has been established.

COMMITTEE ACTION: The P&T Committee voted (14 for, 1 opposed, 1 abstention, 2 absent) to recommend an effective date of 30 days from the final decision date if the Director, TMA, approves the P&T Committee's recommendation.

E. ARB Basic Core Formulary (BCF) Review and Recommendations: The P&T Committee reviewed the ARBs recommended for inclusion on the UF to select a BCF ARB. It had previously been decided that at least one, but no more than three ARBs, could be added to the BCF, based on the outcome of relative clinical effectiveness and relative cost effectiveness determinations.

Within the MTFs, the majority of ARB usage is for treating hypertension, and not for treating chronic heart failure or Type 2 diabetic nephropathy. Although valsartan, candesartan, irbesartan, and losartan have additional indications, which are of importance in the UF at the MTF setting, selecting one BCF ARB with a sole indication for hypertension is sufficient to meet the needs of the majority of patients. The relative clinical effectiveness review demonstrated that all seven ARBs have similar efficacy, safety, and tolerability for treating hypertension. The six remaining UF ARBs were reviewed for placement on the BCF for the treatment of hypertension. The same process used for the UF relative cost-effectiveness decision, i.e., a cost-minimization analysis

(CMA) followed by a budget impact analysis (BIA), was employed for the BCF decision. The CMA revealed, and the BIA confirmed, that telmisartan was the most cost-effective ARB for the MTF point of service. Based on the relative clinical and cost effectiveness analyses, the P&T Committee recommended placing telmisartan on the BCF. MTFs can add additional ARBs to their local formularies if needed to meet the needs of their specific patient populations.

Conclusion: The P&T Committee concurred with the recommendation to place telmisartan as the sole ARB on the BCF.

COMMITTEE ACTION: The P&T Committee voted (15 for, none opposed, 2 abstentions, 1 absent) to recommend telmisartan as the BCF agent.

12. PROTON PUMP INHIBITORS (PPIs) DRUG CLASS REVIEW

A. PPI Relative Clinical Effectiveness: The P&T Committee evaluated the relative clinical effectiveness of all the FDA-approved proton pump inhibitors available in the U.S. The PPI therapeutic class was defined as omeprazole (Prilosec, Zegerid & generics), lansoprazole (Prevacid), rabeprazole (Aciphex), pantoprazole (Protonix) and esomeprazole (Nexium). The clinical review included consideration of pertinent information from a variety of sources determined by the P&T Committee to be relevant and reliable, including but not limited to sources of information listed in 32 C.F.R. 199.21(e)(1). The P&T Committee was advised that there is a statutory presumption that pharmaceutical agents in a therapeutic class are clinically effective and should be included on the UF unless the P&T Committee finds by a majority vote that a pharmaceutical agent does not have a significant, clinically meaningful therapeutic advantage in terms of safety, effectiveness, or clinical outcome over the other pharmaceutical agents included on the UF in that therapeutic class.

PPIs are among the top 10 MHS drug class expenditures. The P&T Committee agreed that in the MHS, PPIs are not recommended as first-line agents for treating gastroesophageal reflux disease (GERD), and they are not intended for the immediate relief of infrequent GERD symptoms. For GERD symptom relief, PPIs are best used after lifestyle modification, antacid, and histamine-2 (H2) blocker therapies have failed. PPIs are first-line therapy for peptic ulcer disease (PUD), whether non-steroidal anti-inflammatory drug (NSAID)-induced, associated with *Helicobacter pylori* infection, or due to a hypersecretory condition.

1.) Efficacy: Although FDA indications differ slightly amongst the PPIs, the vast majority of studies found no significant difference in efficacy in treating GERD and PUD. Minor differences in clinical utility, such as pediatric indication, possible need for dosage adjustment in hepatic failure, and availability of alternative dosage forms were noted. After a review of head-to-head trials and meta-analyses, the P&T Committee concluded that all of the PPIs show similar efficacy when equivalent doses are used.

2.) Safety/Tolerability: The P&T Committee found that PPIs were not significantly different with respect to major contraindications, drug interactions, and adverse drug events. The dropout rates in clinical trials due to adverse events were comparable amongst the five PPIs. All PPIs are pregnancy category B, except omeprazole, which is category C.

Conclusion: The P&T Committee concluded that all PPIs have similar relative clinical effectiveness for treating GERD and PUD. All five PPIs have similar safety and tolerability profiles.

COMMITTEE ACTION*:* The P&T Committee, based upon its collective professional judgment, concluded that all five PPIs demonstrate similar relative clinical effectiveness. (16 for, 0 opposed, 1 abstained, 1 absent).

B. PPI Uniform Formulary Relative Cost Effectiveness: In considering the relative cost effectiveness of pharmaceutical agents in this class, the P&T Committee evaluated the costs of the agents in relation to the safety, effectiveness, and clinical outcomes of the other agents in the class. Information considered by the P&T Committee included but was not limited to sources of information listed in 32 C.F.R. 199.21(e)(2). Two analyses were used to determine the relative cost-effectiveness of agents within the PPI therapeutic class; a pharmacoeconomic analysis using cost-minimization techniques, and a budget impact analysis (BIA). Cost-minimization (CMA) was chosen for the pharmacoeconomic analysis because the clinical analysis, determined the outcomes of interest (effectiveness, safety, and tolerability) to be similar among all the PPIs.

Results of the CMA showed omeprazole to be the most cost-effective PPI across all points of service (MTF, Retail, Mail), followed by rabeprazole, lansoprazole, and pantoprazole. It was determined that esomeprazole was not cost effective relative to the other PPIs

The results of the CMA were then incorporated into a BIA, which accounts for other factors and costs associated with a potential decision regarding formulary status of PPIs within the UF. These factors included: market share migration, cost reduction associated with non-formulary cost shares, medical necessity processing fees, and switch costs. The results of the budget impact analysis further confirmed the results of the CMA. Esomeprazole was found not to be cost effective relative to the other PPIs.

Conclusion: The P&T Committee concluded that esomeprazole was not cost effective relative to the other PPIs. Taking into consideration the conclusions from the relative clinical effectiveness and relative cost effectiveness determinations of the PPIs and other relevant factors, the P&T Committee recommended that esomeprazole's status be changed from formulary to non-formulary, with rabeprazole, lansoprazole, and pantoprazole maintaining formulary status with the formulary cost share, and omeprazole maintaining formulary status with a generic cost share.

COMMITTEE ACTION: The P&T Committee, based upon its collective professional judgment, voted (14 for, 2 opposed, 1 abstained, 1 absent) to recommend non-formulary status for esomeprazole, with rabeprazole, lansoprazole, and pantoprazole maintaining formulary status at the formulary cost share, and omeprazole maintaining formulary status at the generic cost share.

C. PPI Uniform Formulary Medical Necessity Criteria: Based on the clinical evaluation of esomeprazole, and the conditions for establishing medical necessity for a non-formulary medication provided for in the Uniform Formulary rule, the P&T Committee recommended the following medical necessity criteria for esomeprazole.

1.) Use of all formulary PPIs (omeprazole, rabeprazole, lansoprazole, and pantoprazole) is contraindicated, and the use of esomeprazole is not contraindicated.

2.) The patient has experienced or is likely to experience significant adverse effects from all the formulary PPIs (omeprazole, rabeprazole, lansoprazole, and pantoprazole), and the patient is reasonably expected to tolerate esomeprazole.

3.) Use of the formulary PPIs (omeprazole, rabeprazole, lansoprazole, and pantoprazole) resulted in therapeutic failure, and the patient is reasonably expected to respond to esomeprazole.

4.) The patient has previously responded to the non-formulary esomeprazole, and changing to a formulary PPIs (omeprazole, rabeprazole, lansoprazole, and pantoprazole) would incur unacceptable risk.

COMMITTEE ACTION: The P&T Committee voted (16 for, 0 opposed, 1 abstention, 1 absent) to approve the medical necessity criteria.

D. PPI Uniform Formulary Implementation Plan: Because a substantial number of patients are currently receiving esomeprazole from one of the three MHS pharmacy points of service (138,739 patients, 13.4 % of all patients receiving PPIs) the P&T Committee proposed a 90-day transition period for implementation of the decision to change esomeprazole to a non-formulary drug on the UF. Patients wishing to fill prescriptions for esomeprazole at retail network pharmacies or the TMOP would then have to pay the non-formulary cost share unless medical necessity for esomeprazole is established by the beneficiary and/or his or her provider.

Prior to the implementation of the UF, the former DoD P&T Committee had made a decision that prescriptions for esomeprazole could not be filled through the TMOP, unless medical necessity was validated. If the Director, TMA, concurs in the P&T Committee's recommendation, prescriptions for esomeprazole may be filled through the TMOP, but will require payment of the non-formulary cost share of $22. Beneficiaries who already have a medical necessity validation on file at the TMOP are required to re-establish medical necessity for esomeprazole under the medical necessity criteria approved by the Director, TMA, in order to receive esomeprazole at the formulary cost share.

MTFs will not be allowed to have esomeprazole on their local formularies. MTFs will be able to fill non-formulary requests for esomeprazole only if both of the following conditions are met: 1) the prescription must be written by a MTF provider, and 2) the beneficiary and/or his or her provider must establish medical necessity for esomeprazole. MTFs may (but are not required to) fill an esomeprazole prescription written by a non-MTF provider to whom the patient was referred, as long as medical necessity has been established.

COMMITTEE ACTION: The P&T Committee voted (16 for, 0 opposed, 1 abstention, 1 absent) to recommend an effective date of 90 days from the final decision date (the date that DoD P&T Committee minutes are signed by the Director, TMA, approving the P&T Committee's recommendation).

***E. PPI BCF Review and Recommendations*:** The P&T Committee reviewed the PPIs recommended for inclusion on the UF to select a BCF PPI. It had previously been decided that at least one but no more than two PPIs could be added to the BCF, based on the outcome of the relative clinical effectiveness and relative cost effectiveness determinations.

The same process for the UF decision was used for the BCF decision, which consisted of evaluating the relative cost-effectiveness with a cost-minimization analysis (CMA),

followed by a budget impact analysis (BIA). The CMA revealed, and the BIA confirmed, that omeprazole (generic) and rabeprazole (Aciphex) were the most cost-effective PPIs for the MTF point of service. Based on the relative clinical and cost-effectiveness, the P&T Committee recommended placing omeprazole (generic) and rabeprazole (Aciphex) on the BCF. However, omeprazole suspension (Zegerid) and Prilosec 40 mg were not included on the BCF, because they were less cost-effective than the generic omeprazole.

Conclusion: Omeprazole and rabeprazole were recommended for inclusion on the BCF. Omeprazole suspension (Zegerid) and Prilosec 40 mg were not included on the BCF, because they were less cost-effective than the generic omeprazole.

COMMITTEE ACTION: The P&T Committee voted (16 for, 0 opposed, 1 abstained, 1 absent) to recommend that omeprazole and rabeprazole be on the BCF.

14. ADJOURNMENT

The second day of the meeting adjourned at 1730 hours on February 16, 2005. The dates of the next meeting are May 16–19, 2005.

Chairperson

List of Appendices

Appendix A: Recommended Changes to Quantity Limits

Medications	Committee Recommendation	Comments
General Quantity Limit Rules		
Medications for the treatment of erectile dysfunction (ED) Phosphodiesterase-5 (PDE-5) inhibitors [sildenafil (Viagra), tadalafil (Cialis), and vardenafil (Levitra)] Injectable / intraurethral prostaglandins [alprostadil] injection (Caverject, Edex); alprostadil intraurethral pellet (Muse)]	Quantity limits will apply to all injectable/intraurethral prostaglandins and PDE-5 inhibitors for the treatment of ED, including new FDA-approved medications and new formulations of existing medications as soon as they become available, and will be adjusted as necessary to accommodate changes in recommended dosing regimens and commercial package sizes available. Quantity limits will be based on the following: 6 tablets, injections, or intraurethral pellets per 30-day supply or 18 per 90-day supply, consistent with current quantity limits for PDE-5 inhibitors and injectable/intraurethral prostaglandins. This quantity limit will apply collectively to all strengths and formulations of all injectable/intraurethral prostaglandins and PDE-5 inhibitors for the treatment of ED.	The rule would represent a change from quantity limits currently in place for the PDE-5 inhibitors and the injectable / intraurethral prostaglandins (as listed on the TMA Pharmacy website at www.tricare.osd.mil/pharmacy/quant_limits.cfm#ED) in that it provides for a collective quantity limit for this entire group of medications. Currently, collective quantity limits are in place for PDE-5 inhibitors and for injectable / intraurethral prostaglandins, but they do not apply across the entire group of medications.
5-HT3 receptor antagonists (antiemetic medications) Dolasetron (Anzemet) Granisetron (Kytril) Ondansetron (Zofran)].	Quantity limits will apply to all 5-HT3 receptor antagonists, including new FDA-approved medications and new formulations of existing medications as soon as they become available, and will be adjusted as necessary to accommodate changes in recommended dosing regimens and commercial package sizes available. Quantity limits for these medications will be set based on the following factors: quantities sufficient to allow for chemotherapy prophylaxis and post-operative use based on recommended dosing regimens, taking into account FDA safety recommendations in product labeling and other safety concerns; commercial package sizes; and operational requirements.	Quantity limits are currently in place for the three available 5-HT3 receptor antagonists, as listed on the TMA Pharmacy website at www.tricare.osd.mil/pharmacy/quant_limits.cfm#Antiemetics.
5HT-1 receptor agonists ("triptans) for the treatment of migraine Almotriptan (Axert) Eletriptan (Relpax) Frovatriptan (Frova) Naratriptan (Amerge) Rizatriptan (Maxalt) Sumatriptan (Imitrex) Zolmitriptan (Zomig)	Quantity limits will apply to all 5HT1 receptor agonists ("triptans") for the treatment of migraine, including new FDA-approved medications and new formulations of existing medications as soon as they become available, and will be adjusted as necessary to accommodate changes in recommended dosing regimens and commercial package sizes available. Quantity limits for these medications will be set based on the following factors: sufficient quantities to allow for recommended dosing regimens for the treatment of migraine, not to exceed the treatment of an average of more than 4 migraine attacks in a 30-day period based on FDA safety recommendations in product labeling; other safety concerns; commercial package sizes; and operational requirements.	Quantity limits are currently in place for the seven available 5HT-1 receptor agonists ("triptans") for the treatment of migraine, as listed on the TMA Pharmacy website at www.tricare.osd.mil/pharmacy/quant_limits.cfm#Antimigraine.

Medications	Committee Recommendation	Comments
Dihydroergotamine products for the treatment of migraine Dihydroergotamine nasal spray (Migranal) Dihydroergotamine injection (DHE-45, generics)	Quantity limits will apply to all dihydroergotamine products for the treatment of migraine, including new FDA-approved medications and new formulations of existing medications as soon as they become available, and will be adjusted as necessary to accommodate changes in recommended dosing regimens and commercial package sizes available. Quantity limits for these medications will be set based on the following factors: sufficient quantities to allow for recommended dosing regimens for the treatment of migraine, not to exceed more than 4 mg of the nasal spray or more than 6 mL of the injectable product per week, based on FDA safety recommendations in product labeling; other safety concerns; commercial package sizes; and operational requirements.	Quantity limits are currently in place for these medications, as listed on the TRICARE Management Activity Pharmacy website at www.tricare.osd.mil/pharmacy/quant_limits.cfm#Antimigraine.
Fertility agents (injectable gonadotropins) Follitropin alpha Follitropin beta Menotropins Urofollitropin	Quantity limits will apply for all injectable gonadotropins for the treatment of infertility, including new FDA-approved medications and new formulations of existing medications as soon as they become available, and will be adjusted as necessary to accommodate changes in recommended dosing regimens and commercial package sizes available. Quantity limits will be based on the following: 3600 IU (or equivalent) per 30 day supply, no refills, in all pharmacy points of service, consistent with current quantity limits for injectable prostaglandins. This quantity limit will apply collectively to all injectable gonadotropins (no more than 3600 IU of any combination of products per 30 days in any pharmacy point of service, no refills).	This would represent a change from quantity limits currently in place for the injectable gonadotropins (as listed on the TMA Pharmacy website at www.tricare.osd.mil/pharmacy/quant_limits.cfm#Fertility) in that it provides for a collective quantity limit for this group of medications. Currently, quantity limits are in place for injectable gonadotropins but they do not apply across the entire class of medications. A collective quantity limit is desirable to prevent patients from accumulating excessive quantities of injectable gonadotropins by submitting prescriptions for two or more different injectable gonadotropins during the same time period.
Nasal inhalers for the treatment of allergic and nonallergic rhinitis Multiple products, including nasal corticosteroids, ipratropium, and antihistamines	Quantity limits will apply to all nasal inhalers for the treatment of allergic and nonallergic rhinitis, including new FDA-approved medications and new formulations of existing medications as soon as they become available, and will be adjusted as necessary to accommodate changes in recommended dosing regimens and commercial package sizes available. Quantity limits for these medications will be set based on the following factors: sufficient quantities to allow for recommended dosing regimens for the treatment of allergic and nonallergic rhinitis, taking into account FDA safety recommendations in product labeling, and other safety concerns; commercial package sizes; and operational requirements.	Quantity limits are currently in place for the medications in this category, as listed on the TRICARE Management Activity Pharmacy website at www.tricare.osd.mil/pharmacy/quant_limits.cfm#Nasal.

Medications	Committee Recommendation	Comments
Oral inhalers and inhalant solutions for the treatment of asthma, chronic obstructive lung disease, or allergies Multiple products, including oral inhaled corticosteroids, bronchodilators, mast cell stabilizers, and combination products	Quantity limits will apply to all oral inhalers and inhalant solutions for the treatment of asthma, chronic obstructive lung disease, or allergies, including new FDA-approved medications and new formulations of existing medications as soon as they become available, and will be adjusted as necessary to accommodate changes in recommended dosing regimens and commercial package sizes available. Quantity limits for these medications will be set based on the following factors: sufficient quantities to allow for recommended dosing regimens, taking into account FDA safety recommendations in product labeling and other safety concerns; sufficient quantities to allow for an extra inhaler at school or place of business for those inhalers (multi-dose inhalers or dry powder inhalers) commonly given as needed for acute treatment of bronchospasm; commercial package sizes; and operational requirements.	Quantity limits are currently in place for the medications in this category, as listed on the TRICARE Management Activity Pharmacy website at www.tricare.osd.mil/pharmacy/quant_limits.cfm#Oral. The rule would represent a change from current quantity limits by allowing an extra inhaler for "rescue" medications for acute treatment of bronchospasm (e.g., albuterol).
Tramadol-containing products Tramadol (Ultram, generics) Tramadol/acetaminophen (Ultracet)	Quantity limits will apply to tramadol-containing products, including new FDA-approved medications and new formulations of existing medications as soon as they become available, and will be adjusted as necessary to accommodate changes in recommended dosing regimens and commercial package sizes available. Quantity limits for these medications will be set based on the following factors: sufficient quantities to allow for recommended dosing regimens, taking into account FDA safety recommendations in product labeling and other safety concerns; commercial package sizes; and operational requirements. These quantity limits would apply collectively to all tramadol-containing products, unless a newly approved product required a more stringent limitation for safety reasons.	A collective quantity limit is currently in place for tramadol (Ultram, generics) and tramadol / acetaminophen (Ultracet) (as listed on the TRICARE Management Activity Pharmacy website at www.tricare.osd.mil/pharmacy/quant_limits.cfm#Miscellaneous), based on FDA safety recommendations in product labeling (maximum of no more than 8 tablets per 24 hour period).
Specific Changes to Quantity Limits		
Dihydroergotamine nasal spray (Migranal)	Change in quantity limits to 16 amps per 30 days; 48 amps per 90 days	Dihydroergotamine nasal spray (Migranal) is used for the treatment of migraine. It comes in a kit with 4 ampules. Each 1 mL ampule contains 4 mg. A dose is 2 (0.5 mg per spray, 1 mg total). The weekly max per FDA safety recommendations is 4 mg; however, a patient may use up to 3 mg in a 24 hour period. A patient may potentially use as many as 4 ampules per week if he or she only uses one dose per ampule. The P&T Committee agreed that the current quantity limits for this medications (30 amps per 30 days; 90 amps per 90 days) are too high, and recommended changing them to 16 amps per 30 days; 48 amps per 90 days.

Medications	Committee Recommendation	Comments
Azelastine nasal spray (Astelin)	Establishment of quantity limits: 1 bottle per 30 days or 3 bottles per 90 days	Azelastine (Astelin) is an antihistamine indicated for the treatment of seasonal allergic rhinitis and vasomotor rhinitis. It is packaged in bottles containing approximately 200 sprays (about 1 months supply). Based on the precedent for quantity limits for other nasal inhalers for the treatment of allergic and nonallergic rhinitis, the P&T Committee recommended a quantity limit of 1 bottle per 30 days; 3 bottles per 90 days.
Tazarotene 0.05% and 0.1% cream (Tazorac)	Establishment of quantity limits: 60 gm (1 large tube) per 30 days or 180 gm (3 large tubes) per 90 days	Currently, quantity limits exist for tazarotene (Tazorac) gel, but not for tazarotene (Tazorac) cream. Both formulations are used for the treatment of acne and psoriasis. The P&T Committee agreed that tazarotene (Tazorac) cream should have a quantity limit consistent with that currently in place for tazarotene gel, which equates to 1 large tube per 30 days, 3 large tubes per 90 days. The P&T Committee noted that tazarotene cream is also available by the brand name Avage, which is not a covered benefit under TRICARE, since the sole FDA-approved indication is for wrinkling, hypopigmentation, and lentigines (age spots).
Azithromycin (Zithromax) 250- and 600-mg tablets	Deletion of quantity limits	The P&T Committee agreed that while azithromycin 250 mg is a costly, widely used antibiotic that has a high potential for inappropriate use, most of that inappropriate use is for the treatment of viral infections. The existence of a quantity limit is unlikely to influence such use. The P&T Committee also did not see the need for a quantity limit for the 600-mg strength of azithromycin, which is less commonly used and unlikely to be inappropriately prescribed, particularly since the quantity limit currently in place is not adequate for the treatment of disseminated Mycobacterium avium complex (MAC) disease.
Dornase alpha inhalation solution (Pulmozyme)	Deletion of quantity limit	This product is given by nebulization once to twice daily for the treatment of cystic fibrosis. Based on previous DoD P&T Committee minutes, the current quantity limits were set to allow for an alternative dosing regimen (4 ampules twice daily, two weeks on, two weeks off). It is not clear that this regimen is currently in clinical use. Since the quantity limits are probably set too high to influence use and since the potential for inappropriate use is unclear for this specialized indication, the P&T Committee recommended deleting the quantity limit for dornase alpha.

Medications	Committee Recommendation	Comments
Fluconazole (Diflucan, generics) 150 mg tablets	Deletion of quantity limit	Historically, the 150 mg tablet of fluconazole was far more costly than other strengths since it was intended and specially packaged for single-dose use for the treatment of vaginal candidiasis. Since fluconazole is available as 50-, 100-, and 200-mg tablets, there was no justification for using the 150-mg tablets for other indications, which typically require daily dosing. Fluconazole 150 mg tablets are now generically available and available at a much lower cost ($6.63 per tablet in 2001 for brand name Diflucan vs. $0.18 in Feb 05 for the generic equivalent, based on FSS prices). Although there is still little reason to use the 150 mg strength of fluconazole for other indications, the P&T Committee agreed that the cost differential between the strengths no longer warrants the existence of a specific quantity limit.
Imiquimod cream (Aldara)	Deletion of quantity limit	Imiquimod has a long-standing FDA indication for genital/perianal warts (3 times per week for maximum of 16 weeks) and two new indications, for actinic keratoses (2 times per week for 16 weeks) and superficial basal cell carcinoma (5 times per week for 6 weeks). Labeling for superficial basal cell carcinoma recommends dispensing no more than 3 boxes (36 individual packets) per 6-week treatment period. The current quantity limit for imiquimod is for 12 packets per 30 days or 36 packets per 90 days, which is not adequate for superficial basal cell carcinoma based on approved dosing. Imiquimod is a costly medication and the potential for wastage appears relatively high. Given the new indication, however, the P&T Committee recommended deleting the quantity limit for imiquimod. They requested that the PEC monitor imiquimod utilization for excessive use.
Testosterone buccal system (Striant)	Deletion of quantity limit	This product is the only testosterone replacement product for which a specific quantity limit is listed. This dosage form does not appear to be any more likely to be used inappropriately than other testosterone replacement products.

Appendix B – Newly Approved Drugs

Medication & Mechanism of Action	FDA approval date; FDA-approved indications	Committee Recommendation
Acamprosate (Campral) tabs; Forest; glutamate receptor modulator (alcohol deterrent)	Jul 04: Maintenance of abstinence from alcohol in patients with alcohol dependence who are abstinent at treatment initiation. Treatment with Campral should be part of a comprehensive management program that includes psychosocial support.	No Uniform Formulary recommendation at this meeting. Consideration of Uniform Formulary status deferred until drug class is reviewed.
Apomorphine (Apokyn) SQ injection; Bertek ; dopamine agonist	April 04: Acute, intermittent treatment of hypomobility, "off" episodes ("end-of-dose wearing off" and unpredictable "on/off" episodes) associated with advanced Parkinson's Disease. Has been studied as an adjunct to other medications. Note: Not available at TMOP due to controlled distribution requirements.	No Uniform Formulary recommendation at this meeting. Consideration of Uniform Formulary status deferred until drug class is reviewed.
Duloxetine (Cymbalta) capsules; Eli Lilly; serotonin norepinephrine reuptake inhibitor (SNRI)	Aug 04: Treatment of major depressive disorder (MDD). Also indicated for management of neuropathic pain associated with diabetic peripheral neuropathy.	No Uniform Formulary recommendation at this meeting. Consideration of Uniform Formulary status deferred until drug class is reviewed.
Erlotinib (Tarceva) tabs; Genentech / OSI; human epidermal growth factor receptor type 1 (HER1/EGFR1) tyrosine kinase inhibitor	Nov 04: Treatment of patients with locally advanced or metastatic non-small cell lung cancer after failure of at least one prior chemotherapy regimen.	Quantity limits recommended due to precedent set by the other HER1/EGFR1, gefitinib (Iressa); potential for wastage; and high cost: Limit of 30 day supply in retail, 45 day supply in TMOP, up to 45 day supply in MTFs. No multiple fills for multiple cost shares in retail and TMOP. Consideration of Uniform Formulary status deferred until drug class is reviewed.
Ezetimibe / simvastatin (Vytorin) tabs; Merck Schering Plough; cholesterol absorption inhibitor plus statin	Aug 04: Primary Hypercholesterolemia: Indicated as adjunctive therapy to diet for the reduction of elevated total-C. LDL-C, Apo B, TG and non-HDL-C, and to increase HDL-C in patients with primary (heterozygous familial and non-familial) hypercholesterolemia or mixed hyperlipidemia. Homozygous Familial Hypercholesterolemia: Indicated for the reduction in elevated total-C and LDL-C in patients with homozygous familial hypercholesterolemia, as an adjunct to other lipid-lowering treatments (e.g., LDL apheresis) or if such treatments are unavailable.	No Uniform Formulary recommendation at this meeting. Consideration of Uniform Formulary status deferred until drug class is reviewed.

Medication & Mechanism of Action	FDA approval date; FDA-approved indications	Committee Recommendation
Gemifloxacin (Factive) tabs; Oscient; fluoroquinolone antibiotic	April 03: Community-acquired pneumonia (includes multi-drug resistant strains of *Strep. pneumoniae);* and acute exacerbations of chronic bronchitis	No Uniform Formulary recommendation at this meeting. Consideration of Uniform Formulary status deferred until drug class is reviewed. Quantity limits recommended based on the maximum 7-day course of therapy and FDA safety recommendations noting a much higher incidence of rash—which can be severe—if treated for more than 10 days. The product is packaged only in 5s and 7s. Recommendation: Limit of 7 days supply (one course of therapy) per 30 days in retail, TMOP, and MTFs.
Lanthanum carbonate (Fosrenol) chewable tabs; Shire Phosphate binder (rare earth metal; trivalent cation)	Oct 04: Indicated to reduce serum phosphate in patients with End Stage Renal Disease (ESRD)	No Uniform Formulary recommendation at this meeting. Consideration of Uniform Formulary status deferred until drug class is reviewed.
Overactive Bladder Medications		
Darifenacin (Enablex) sustained release tabs; Novartis; muscarinic antagonist	Dec 04: Treatment of overactive bladder with symptoms of urge urinary incontinence, urgency and frequency	No Uniform Formulary recommendation at this meeting. Consideration of Uniform Formulary status deferred until drug class is reviewed.
Solifenacin (Vesicare) tabs; GSK/Yamanouchi; muscarinic antagonist	Nov 04: Treatment of overactive bladder with symptoms of urge urinary incontinence, urgency and frequency	
Trospium (Sanctura) tabs; Indevus; muscarinic antagonist	May 04: Treatment of overactive bladder with symptoms of urge urinary incontinence, urgency and frequency	
Rifaximin (Xifaxan) tabs; Salix; rifampin derivative antibiotic (nonabsorbed)	May 04: Treatment of patients $\geq$12 years of age with traveler's diarrhea caused by non-invasive strains of *Escherichia coli.* Rifaximin should not be used in patients where *Campylobacter jejuni, Shigella* spp, or S*almonella* spp are suspected as causative pathogens. Rifaximin should not be used for diarrhea complicated by fever of bloody stools. (Orphan status for hepatic encephalopathy)	No Uniform Formulary recommendation at this meeting. Consideration of Uniform Formulary status deferred until drug class is reviewed.

Medication & Mechanism of Action	FDA approval date; FDA-approved indications	Committee Recommendation
Telithromycin (Ketek) tabs; Sanofi-Aventis; ketolide / macrolide antibiotic	April 04: Treatment of patients 18 years and older with the following conditions: community-acquired pneumonia due to *Streptococcus pneumoniae* (includes multi-drug resistant isolates [MDRSP]), *Haemophilus influenzae, Moraxella catarrhalis, Chlamydophila pneumoniae*, or *Mycoplasma pneumoniea***;** acute exacerbations of chronic bronchitis (AECB) due to *Streptococcus pneumoniae, Haemophilus influenzae*, or *Moraxella catarrhalis***;** sinusitis due to *Streptococcus pneumoniae, Haemophilus influenzae*, or *Moraxella catarrhalis* or *Staphylococcus aureus.*	No Uniform Formulary recommendation at this meeting. Consideration of Uniform Formulary status deferred until drug class is reviewed.
Tinidazole (Tindamax) tabs; Presutti Labs; anti-protozoal antibiotic	May 04: Treatment of trichomoniasis in post-pubertal female and male patients caused by *T. vaginalis*; giardiasis caused by *G. duodenalis* (also termed *G. lamblia*) in both adults and pediatric patients**;** intestinal amebiasis (amebic dysentery) and amebic liver abscess caused by *E. histolytica* in both adults and pediatric patients older than 3 years of age.	No Uniform Formulary recommendation at this meeting. Consideration of Uniform Formulary status deferred until drug class is reviewed.

14 July 2004

DECISION PAPER:
JULY 2004 PHARMACY AND THERAPEUTICS COMMITTEE RECOMMENDATIONS

7. BASIC CORE FORMULARY (BCF) CHANGES

A. Estrogen Replacement Therapy Patches (Esclim):

The Committee recommended removing Esclim from the BCF because the price increased from $5.20 per cycle to $27.50 per cycle. (See paragraph 7. A. on page 4 of P&T Committee minutes)

TMA Director Decision: ■ Approved □ Disapproved
□ Approved, but modified as follows:

The Committee recommended changing the BCF listing to "estradiol patch" with no specific brand listed. (See paragraph 7. A. on page 4 of P&T Committee minutes)

TMA Director Decision: ■ Approved □ Disapproved
□ Approved, but modified as follows:

B. Ciprofloxacin (Cipro, generics):

The Committee recommended adding ciprofloxacin to the BCF because it is a cost-effective alternative to other fluoroquinolones for treating susceptible infections. (See paragraph 7. B. on pages 4 and 5 of P&T Committee minutes)

TMA Director Decision: ■ Approved □ Disapproved
□ Approved, but modified as follows:

C. Lamivudine/Zidovudine (Combivir):

The Committee recommended not adding Combivir to the BCF. (See paragraph 7. C. on page 5 of P&T Committee minutes)

TMA Director Decision: ■ Approved □ Disapproved
□ Approved, but modified as follows:

D. Erythromycin/Sulfisoxazole (Pediazole):

The Committee recommended removing erythromycin ethylsuccinate / sulfisoxazole from the BCF due to increasing microbial resistance, the absence of erythromycin ethylsuccinate / sulfisoxazole from current guidelines for acute otitis media, and low utilization at MTFs. (See paragraph 7. D. on page 5 of the P&T Committee minutes).

TMA Director Decision: ■ Approved □ Disapproved
□ Approved, but modified as follows:

E. Ramipril (Altace):

The Committee recommended removing ramipril from the BCF because it is now significantly less cost effective than the other ACE inhibitors on the BCF. (See paragraph 7. E. on page 5 of the P&T Committee minutes)

TMA Director Decision: ■ Approved □ Disapproved
□ Approved, but modified as follows:

12. PRIOR AUTHORIZATIONS

A. ***COMMITTEE ACTION****:* The Committee recommended retaining existing prior authorizations criteria for the following drugs (See paragraph 12. A. on page 7 of P&T Committee minutes and Appendix A for the rationale):

- Adalimumab (Humira®)

TMA Director Decision: ■ Approved □ Disapproved
□ Approved, but modified as follows:

- Anakinra (Kineret®)

TMA Director Decision: ■ Approved □ Disapproved
□ Approved, but modified as follows:

- Efalizumab (Raptiva®)

TMA Director Decision: ■ Approved □ Disapproved
□ Approved, but modified as follows:

- Ciclopirox (Penlac)

*TMA Director Decision***:** ■ Approved □ Disapproved
□ Approved, but modified as follows:

- Itraconazole (Sporanox)

*TMA Director Decision***:** ■ Approved □ Disapproved
□ Approved, but modified as follows:

- Terbinafine (Lamisil)

*TMA Director Decision***:** ■ Approved □ Disapproved
□ Approved, but modified as follows:

- Human growth hormone (somatropin, somatrem)

*TMA Director Decision***:** ■ Approved □ Disapproved
□ Approved, but modified as follows:

- Injectable gonadotropins

*TMA Director Decision***:** ■ Approved □ Disapproved
□ Approved, but modified as follows:

B. ***COMMITTEE ACTION****:* The Committee recommended continuation of the requirement for prior authorization of etanercept (Enbrel), with the addition of a criterion that covers the new FDA-approved indication for the treatment of adult patients (≥18 years of age) with chronic moderate to severe plaque psoriasis who are candidates for systemic therapy or phototherapy. (See paragraph 12. A. on page 7 and Appendix A of P&T Committee minutes for rationale)

*TMA Director Decision***:** ■ Approved □ Disapproved
□ Approved, but modified as follows:

C. ***COMMITTEE ACTION:*** The Committee recommended continuation of prior authorization of PDE-5 inhibitors, but with modifications designed to improve the efficiency of the prior authorization process. Contingent upon the ASD(HA) rescinding HA Policy 98-040, Practice Guidelines for the Evaluation of Patients Requesting Sildenafil (Viagra) for the Treatment of Male Impotence, the Committee recommended:

- Allowing male patients 50 years of age or older to receive PDE-5 inhibitors without going through the PA process, and
- Eliminating the drug interaction with nitrates from the PA criteria.

Note: The cumulative quantity limit of 6 tablets per 30 days in the retail network or 18 tablets per 90 days in the TMOP remain in effect. (See paragraph 12 B. on page 8 and Appendix A of P&T Committee minutes for rationale)

*TMA Director Decision***:** ■ Approved □ Disapproved

□ Approved, but modified as follows:

DECISION ON RECOMMENDATIONS

TMA Director decisions are as annotated above.

William Winkenwerder, Jr., M.D.
Date:
OCT 5 2004

Department of Defense
Pharmacy and Therapeutics Committee Minutes

14 July 2004

1. CONVENING

The DoD P&T Committee convened at 0800 hours on 13 and 14 July 2004 at the DoD Pharmacoeconomic Center (PEC), Fort Sam Houston, Texas.

2. VOTING MEMBERS PRESENT

CAPT Patricia Buss, MC	DoD P& T Committee Chair
COL Daniel Remund, MS	DoD P& T Committee Recorder
Col James Young, BSC (Representing COL William Davies)	Deputy Director, DoD Pharmacy Programs, TMA (Representing Director, DoD Pharmacy Programs, TMA)
Lt Col Gordon Wright Bates, Jr., MC	Air Force, OB/GYN Physician
Maj Nick Conger, MC	Air Force, Physician at Large
Col Phil Samples, BSC	Air Force, Pharmacy Officer
CDR William Hall, MC	Navy, Internal Medicine Physician
LCDR Suzanne Haney, MC (via VTC)	Navy, Pediatrics Physician
CDR Brian Alexander, MC	Navy, Physician at Large
LT Joseph Lawrence, MSC	Navy, Pharmacy Officer
COL Doreen Lounsbery, MC	Army, Internal Medicine Physician
MAJ Franklin H. Hauger, MC	Army, Family Practice Physician
COL Joel Schmidt, MC	Army, Physician at Large
COL Kent Maneval, MS (Representing MAJ Travis Watson, MS)	Joint Readiness Clinical Advisory Board (Representing Army, Pharmacy Officer)
CDR Patrick Marshall	Coast Guard, Pharmacy Officer
LTC Donald DeGroff, MS	Contracting Officer Representative, TMOP
CDR Jill Pettit, MSC	Contracting Officer Representative, TRRx
Joe Canzolino	Department of Veterans Affairs

VOTING MEMBERS ABSENT

COL Greg Wickern, MC (deployed)	Air Force, Internal Medicine Physician

NON-VOTING MEMBERS PRESENT

Howard Altschwager	Deputy General Counsel, TMA
Martha Taft	Resource Management Directorate, TMA
MAJ John Howe, MS	Defense Supply Center Philadelphia

NON-VOTING MEMBERS ABSENT

None	

OTHERS PRESENT

COL William Davies, MS	DoD Pharmacy Program Director, TMA
CDR Mary Fong	Coast Guard, Pharmacy Officer Alternate
COL Mike Heath, MS, USA (Via VTC July 13th only)	Army Pharmacy Consultant, Chairman Pharmacy Board of Directors
CAPT Betsy Nolan, MSC (Via VTC July 13th only)	Navy Pharmacy Specialty Leader
CDR Denise Graham, MSC	DoD Pharmacoeconomic Center
CDR Ted Briski, MSC	DoD Pharmacoeconomic Center
CAPT Don Nichols, MC	DoD Pharmacoeconomic Center
Lt Col Dave Bennett, BSC	DoD Pharmacoeconomic Center
Lt Col Barb Roach, MC	DoD Pharmacoeconomic Center
CPT Jill Dacus, MC	DoD Pharmacoeconomic Center
Shana Trice	DoD Pharmacoeconomic Center
Dave Bretzke	DoD Pharmacoeconomic Center
Angela Allerman	DoD Pharmacoeconomic Center
Eugene Moore	DoD Pharmacoeconomic Center
Julie Liss	DoD Pharmacoeconomic Center
Elizabeth Hearin	DoD Pharmacoeconomic Center
Janet Daily	Department of Veterans Affairs
Paul Vasquez	Defense Supply Center Philadelphia
Lynn Burleson	Assistant General Counsel, TMA
CDR Mark Richerson, MSC	Future PEC Director

3. REVIEW MINUTES OF LAST MEETING

This is the first meeting of the restructured DoD Pharmacy and Therapeutics (P&T) Committee under the new charter established under the authority of 10 U.S.C. 1074g and 32 C.F.R. 199.21. The P&T Committee approved the minutes of the last meeting of the previous Committee with a correction to page 7 Section 6A of the Executive Council minutes regarding prices for salmeterol and formoterol: Based on current FSS prices and recommended dosing regimens, salmeterol costs $44.57 per month compared to $32.63 per month for formoterol.

4. INTERIM DECISIONS/ADMINISTRATIVE ISSUES

None.

5. ORIENTATION/EDUCATION OF THE DOD P&T COMMITTEE

TMA and PEC staff members briefed the Committee on the following:

- Overview of the DoD pharmacy benefit
- Overview of the Uniform Formulary and Basic Core Formulary
- DoD P&T Committee processes under the new charter
- Beneficiary Advisory Panel
- Ethical issues
- Drug class review process
- New drug review process

TMA, PEC, and DSC-P staff are working to revise certain provisions in existing pharmaceutical contracts are in conflict with provisions of the 32 C.F.R 199.21. Additionally, procedures are being developed for DoD to receive price information from pharmaceutical companies for consideration in Uniform Formulary decisions.

6. NATIONAL PHARMACEUTICAL CONTRACTS AND BLANKET PURCHASE AGREEMENTS (BPAS)

A. *New Contracts Awarded* – midazolam HCL 1 mg/mL and 5 mg/mL.

B. *Changes to Existing Contracts*—The next option year was exercised for contracts on the following drugs: ticlopidine, naproxen, propofol, ethinyl estradiol 35 mcg/ethynodiol diacetate 1 mg, ethinyl estradiol 35 mcg/norethindrone 1 mg, norethindrone 35 mcg, ondansetron, digoxin, simvastatin, acyclovir, valproic acid, nicotine patches, glyburide, benztropine, fluphenazine, chlorhexidine, indomethacin, ketoconazole cream, adsorbase ointment, paclitaxel, carbidopa/levodopa, and zolmitriptan.

C. *Contracts Pending Award* – amantadine, enalapril, salsalate, fluocinonide topical, nortriptyline, verapamil SA and insulin.

D. The Committee reviewed utilization and cost data for drug classes where national contracts or blanket purchase agreements currently exist: statins, triptans, fluoroquinolones, leutinizing hormone releasing hormone (LHRH) agonists, ophthalmic prostaglandins, thiazolidinediones (TZDs) and 2nd generation antihistamines. More information about DoD and DoD/VA national pharmaceutical contracts may be found on the Defense Supply Center Philadelphia (DSCP) DMM-Online website at http://dmmonline.dscp.dla.mil/pharm/contractlist.asp. Contract guidance for the oral fluoroquinolones, statins, leutinizing hormone releasing hormone (LHRH) agonists, and triptans are available on the PEC website at www.pec.ha.osd.mil/national_contracts.htm.

7. BASIC CORE FORMULARY (BCF) CHANGES AND CLARIFICATIONS

The committee voted (17 for, 0 opposed, 1 abstained) to require that any requests for BCF additions or deletions from individual providers must be approved by and forwarded through the MTF Pharmacy and Therapeutics Committee before being considered by this committee.

A. *Estrogen Replacement Therapy Patches (Esclim):* Esclim was added to the BCF in May 2003 on the basis of a BPA price of $5.20 per cycle (8 patches = 28 days supply) for all

strengths. Women's First Healthcare, the U.S. distributor of Esclim, filed for Chapter 11 reorganization on May 29, 2004. The FSS contract for Esclim was terminated subsequent to the filing for reorganization. The absence of the FSS contract has caused Esclim's price to increase to $27.50 per month, a 5-fold increase. Women's First Healthcare is in the process of selling their marketing rights to Esclim, but it will likely be one to three months before another FSS contract is in place. Prices for estradiol patches are displayed in Table 1 below.

Table 1. July 2004 FSS Prices per Cycle for Estradiol Patches

Brand	Manufacturer	Dosing Schedule	0.025 mg	0.0375 mg	0.05 mg	0.06 mg	0.075 mg	0.1 mg
Esclim	WFH	Twice weekly	$26.60 (formerly $5.20)	$26.86 (formerly $5.20)	$27.38 (formerly $5.20)		$27.89 (formerly $5.20)	$27.89 (formerly $5.20)
Estraderm	Novartis	Twice weekly			$17.94			$19.36
Climara	Berlex	Once weekly	$7.74	$17.85	$7.74	$18.45	$7.74	$7.74
Vivelle	Novartis	Twice weekly	$19.04	$19.59	$20.86		$20.76	$21.74
Vivelle Dot	Novartis	Twice weekly	$18.07	$16.35	$17.42		$17.21	$18.37
Alora	Watson	Twice weekly	$19.04		$18.22		$21.85	$18.89
Generic	Mylan	Once weekly			$11.18			$11.65

COMMITTEE ACTION: The Committee recommended (17 for, 0 opposed, 1 abstained) to remove Esclim from the BCF and change the BCF listing to "estradiol patch" with no specific brand listed. MTFs can decide if they want to switch to a different estradiol patch or continue to use Esclim with the anticipation that the price of Esclim will be reduced in the near future. The DoD P&T Committee will reconsider the class for BCF and/or Uniform Formulary selections once the pricing issue has resolved.

B. *Ciprofloxacin (Cipro, generics):* Ciprofloxacin prices have decreased significantly due to the availability of generic equivalents for Cipro. As shown in Table 2, ciprofloxacin now costs much less than other fluoroquinolones.

Table 2. July 2004 MTF Fluoroquinolone Prices

Gatifloxacin	Moxifloxacin	Levofloxacin	Ciprofloxacin (Bayer)*	Ciprofloxacin (PAR)	Ciprofloxacin (Ivax)
$1.35/tab (all strengths)	$1.55/tablet (all strengths)	$4.39/250 mg $5.06/500 mg $5.50/750 mg	$0.19/tab (all strengths) $0.40/tab XR	$0.28/250 mg $0.34/500 mg $0.40/750 mg	$0.06/250 mg $0.095/500 mg $0.12/750 mg

*NOTE: Bayer's Cipro prices are only available through direct purchase, not from Prime Vendors (PVs). Prices for Cipro similar to the direct prices from Bayer will be available at PVs in the near future**.** Ciprofloxacin (PAR) prices are based on commercial pricing. Ciprofloxacin (Ivax) are July 2004 FSS prices. Prices for gatifloxacin, moxifloxacin and levofloxacin are based on the most current contract, incentive agreement, and FSS prices, respectively, effective as of July 2004.

Ciprofloxacin lacks good gram-positive coverage, so gatifloxacin is still the preferred fluoroquinolone for the treatment of community acquired pneumonia (CAP) and sinusitis. The gatifloxacin contract allows ciprofloxacin to be on formularies for the treatment of conditions other than CAP or sinusitis. Ciprofloxacin is a cost effective alternative to other fluoroquinolones for treating susceptible infections.

***COMMITTEE ACTION**:* The Committee recommended (17 for, 0 opposed, 1 abstained) addition of ciprofloxacin to the BCF, because it is a cost-effective alternative to other fluoroquinolones for treating susceptible infections.

C. *Lamivudine/Zidovudine (Combivir)*: An MTF provider requested the addition of Combivir (300mg zidovudine plus 150mg lamivudine given BID) to the BCF for HIV post-exposure prophylaxis (PEP). There is currently no medication on the BCF to fulfill the OSHA requirement for PEP. U.S. Public Health Service guidelines for PEP are available on the CDC website at www.cdc.gov/mmwr/preview/mmwrhtml/rr5011a1.htm. Lamivudine and zidovudine are identified in the U.S. Public Health Service guidelines as an option for initial PEP prophylaxis. Some committee members expressed the opinion that this issue was already covered by the OSHA requirement and that medications for PEP prophylaxis should not be specified on the BCF, because they are not a primary care issue.

***COMMITTEE ACTION**:* The Committee recommended (15 for, 1 opposed, 1 abstained, 1 absent from the room) to not add Combivir to the BCF. The Committee reminds MTFs of the requirement to have medications for PEP readily available for their facility healthcare workers in the event of blood borne exposure.

D. *Erythromycin/Sulfisoxazole (Pediazole):* An MTF provider requested removal of erythromycin ethylsuccinate / sulfisoxazole oral suspension (Pediazole) from the BCF. Erythromycin ethylsuccinate / sulfisoxazole is indicated for the treatment of acute otitis media caused by susceptible strains of *Haemophilus influenzae* in children.

The May 2004 guideline from the Subcommittee on Management of Acute Otitis Media (sponsored by the American Academy of Pediatrics and the American Academy of Family Physicians) does not include erythromycin ethylsuccinate / sulfisoxazole. MTF utilization of erythromycin ethylsuccinate / sulfisoxazole is extremely low, about 400 prescriptions per month. Provider responses support the removal of erythromycin ethylsuccinate / sulfisoxazole from the BCF.

***COMMITTEE ACTION**:* The Committee recommended (16 for, 0 opposed, 1 abstained, 1 absent from the room) to remove erythromycin ethylsuccinate / sulfisoxazole from the BCF, due to increasing microbial resistance, absence of erythromycin ethylsuccinate / sulfisoxazole from current guidelines for acute otitis media, and low utilization at MTFs.

E. *Ramipril (Altace):* Ramipril (Altace) has been priced at $0.12 per capsule for the past few years under a voluntary price reduction from Monarch. Monarch recently renegotiated the FSS price for ramipril and discontinued the voluntary price reduction. The FSS price for ramipril is now $0.52-$0.65 / capsule. The two other ACE inhibitors on the BCF are lisinopril ($0.04 to $0.18 per dose) and captopril ($0.01 to $0.05 per dose).

***COMMITTEE ACTION**:* The Committee recommended (16 for, 0 opposed, 1 abstained, 1 absent from the room) to remove ramipril from the BCF because it is now significantly less cost effective than the other ACE inhibitors on the BCF.

8. ANGIOTENSIN RECEPTOR BLOCKERS (ARBs)

Merck submitted a "pre-award" GAO protest of the blanket purchase agreement (BPA) request for price quotes that the Defense Supply Center Philadelphia (DSCP) issued to companies that market ARBs. DSCP decided to cancel the BPA request for price quotes. The Committee intends to evaluate the relative clinical effectiveness and relative cost effectiveness of the ARBs to make recommendations for the Uniform Formulary and BCF at a future meeting.

9. PROTON PUMP INHIBITORS (PPIs)

The Committee reviewed clinical information, and concluded that one or more proton pump inhibitors (PPIs) could potentially be classified as non-formulary on the Uniform Formulary if there are differences in the relative cost effectiveness of the PPIs. The committee intends to evaluate the relative clinical effectiveness and relative cost effectiveness of the PPIs to make recommendations for the Uniform Formulary and BCF at a future meeting.

10. NEW DRUGS

A. *Cinacalcet tablets (Sensipar)* were approved by the FDA in March 2004. Cinacalcet is a calcimimetic and is approved for treating secondary hyperparathyroidism (PTH) in dialysis patients with chronic kidney disease. It is also designated as an orphan drug for treating hypercalcemia associated with parathyroid carcinoma. Cinacalcet increases sensitivity of the calcium-sensing receptor on the PTH gland to extracellular calcium, directly reducing PTH levels, and accordingly reducing serum calcium levels. Serum concentrations of ionized PTH, calcium, phosphorus, and calcium/phosphorus double product normalized in 40% of dialysis patients receiving cinacalcet vs. 5% with placebo ($p = 0.001$). Patients must be monitored for development of hypocalcemia and resultant increased seizure risk.

   COMMITTEE ACTION: The Committee voted (17 for, 0 opposed, 1 abstained) to add cinacalcet to the TMOP formulary without requirements for prior authorization or quantity limits, but not to add it to the BCF.

B. *Sertaconazole 2% cream (Ertaczo)* is a topical antifungal of the azole class, similar to clotrimazole and miconazole. Sertaconazole was approved in December 2003 for treating interdigital tinea pedis in immunocompetent patients older than 12 years of age. Other topical antifungals have additional indications to include tinea cruris, tinea corporis, cutaneous candidiasis, and tinea versicolor. The two clinical trials used for FDA approval compared sertaconazole with a vehicle control, and showed significant improvements in complete cure rates (13.1% vs. 3.3% in study one and 27.3% vs. 4.9% in study two).

   COMMITTEE ACTION: The Committee voted (17 for, 0 opposed, 1 abstained) to add sertaconazole to the TMOP formulary without requirements for prior authorization or quantity limits, but not to add it to the BCF. Since 13 topical antifungals are available in the U.S., the Committee intends to evaluate topical antifungals to make recommendations for the Uniform Formulary and BCF at a future meeting.

11. ENFUVIRTIDE (FUZEON) INJECTION

Enfuvirtide (Fuzeon) is an injectable medication indicated in combination with other antiretroviral agents to treat HIV-1 infection in treatment-experienced patients with evidence of HIV-1 replication despite ongoing antiretroviral therapy. The injections are given subcutaneously twice daily and may be self-administered, although the first injection should be performed under the supervision of a qualified healthcare provider. As of April 26, 2004, enfuvirtide was removed from the restricted distribution program that had previously precluded it from being dispensed by the TMOP.

COMMITTEE ACTION*:* The Committee voted (16 for, 1 opposed, 1 abstained) to add enfuvirtide to the TMOP Covered Injectables List with quantity limit of 1 kit (30-days supply) in the retail network and 2 kits (60-day supply) in the TMOP. The quantity limits are intended to minimize potential wastage of a medication that has a current FSS price of $1,259.38/kit.

12. PRIOR AUTHORIZATIONS

A. *Current Prior Authorizations*: Prior authorizations (PAs) are currently performed in the TMOP and TRRx network pharmacies for:

- Phosphodiesterase-5 (PDE-5) inhibitors (sildenafil, tadalafil, vardenafil)
- Biologic agents for rheumatoid arthritis, psoriasis, or related conditions (etanercept, adalimumab, anakinra, efalizumab)
- Antifungals for onychomycosis (ciclopirox topical solution, itraconazole capsules, terbinafine tablets)
- Fertility agents (injectable gonadotropins)
  - Human growth hormone (somatropin, somatrem)

The Committee reviewed the background, rationale, and criteria for the prior authorizations, which are provided in Appendix A.

COMMITTEE ACTION*:* The Committee chose to make no recommendation (16 for, 0 opposed, 1 abstained, 1 absent from the room) to change prior authorizations with the existing criteria for the following:

- Adalimumab (Humira®)
- Anakinra (Kineret®)
- Efalizumab (Raptiva®)
  - Antifungals for onychomycosis
  - Growth hormone
  - Injectable gonadotropins

COMMITTEE ACTION*:* The Committee chose to make no recommendation (16 for, 0 against, 1 abstained, 1 absent from the room) to change the prior authorization of etanercept, except for adding an additional criterion that covers a new FDA-approved indication for the treatment of adult patients (≥18 years of age) with chronic moderate to severe plaque psoriasis who are candidates for systemic therapy or phototherapy. The Committee decided not to include an age limitation in the PA criteria for etanercept since the medication has clinical trial evidence supporting safety in pediatric patients and an

FDA-approved indication in this age group (for juvenile rheumatoid arthritis). The previous criteria and the revised criteria are included in Appendix A.

B. *PDE-5 Inhibitor PA*: Health Affairs Policy 98-040, Practice Guidelines for the Evaluation of Patients Requesting Sildenafil (Viagra) for the Treatment of Male Impotence, which applies to all PDE-5 inhibitors, imposes prior authorization criteria on PDE-5 inhibitors. TRICARE covers the treatment of erectile dysfunction of organic etiology but not erectile dysfunction that is solely due to psychogenic causes. The PA for PDE-5 inhibitors is primarily based on this coverage issue. As males age, erectile dysfunction is increasingly likely to be at least partially due to organic causes. The efficiency of the PA for PDE-5 inhibitors could be improved by targeting the prior authorization process at the subset of patients who are most likely to have erectile dysfunction of psychogenic etiology (i.e., patients under the age of 50). The existing PDE-5 inhibitor PA criteria also deny coverage to patients who are also receiving nitrates, a well-known, potentially severe drug interaction. The Committee noted that since the policy was first issued, the Pharmacy Data Transaction Service (PDTS) now provides real-time, point-of-care alerts concerning drug interactions between PDE-5 inhibitors and nitrates, therefore, it would not be necessary to include this drug interaction in the PA criteria.

COMMITTEE ACTION: The Committee agreed to have the Chair of the Committee prepare a recommendation to the ASD(HA) to modify or rescind the policy and approve a prior authorization recommended by the Committee instead. If the ASD(HA) concurs in the recommendation to modify or rescind the Health Affairs Policy, the Committee recommended (16 for, 0 against, 1 abstained, 1 absent from the room) to continue prior authorization of PDE-5 inhibitors with modifications designed to improve the efficiency of the prior authorization process:

- Allowing male patients 50 years of age or older to receive PDE-5 inhibitors without going through the PA process, and
- Eliminating the drug interaction with nitrates from the PA criteria.

Since at least 85% of patients obtaining PDE-5 inhibitors through the retail network or mail order are ≥ 50 years of age, this would greatly decrease the administrative costs of performing the PA, while reducing the paperwork required on the part of beneficiaries and providers. The established quantity limits would continue to apply (no more than 6 per 30 days of any combination of PDE-5 inhibitors at retail network pharmacies or 18 per 90 days of any combination of PDE-5 inhibitors at mail order).

13. QUANTITY LIMITS

A. *Etanercept Quantity Limits*: The FDA approval of etanercept for the treatment of psoriasis necessitates a change in the quantity limits, because the recommended adult dosing of etanercept for psoriasis is higher than for other indications for the first 3 months of therapy.

COMMITTEE ACTION: The Committee voted (16 for, 0 opposed, 1 abstained, 1 absent from the room) to set the etanercept quantity limit at a six-week supply in mail order and a four-week supply in retail network pharmacies, with the number of vials dispensed based on the instructions for use on the prescription. The maximum days supply

dispensed at any one time in retail network pharmacies would continue to be limited to four weeks.

B. *Current Quantity Limits*: The Committee reviewed the existing quantity limits.

COMMITTEE ACTION: The Committee reviewed the quantity limits currently in place and voted (16 for, 0 opposed, 1 abstained, 1 absent from the room) that they be continued without change. The Committee members plan to review the list of quantity limits in greater detail and will bring comments to a future meeting. A list of quantity limits is available in Appendix B.

14. ADJOURNMENT

The meeting adjourned at 1730 hours. The date of the next meeting has not been determined.

Appendix A – Prior Authorization Criteria in the TRICARE Mail Order Pharmacy and TRICARE Retail Pharmacy Programs

Background

Prior authorizations (PAs) have been a part of the mail order program since 1999. In the retail network, Managed Care Support Contractors (MCSCs) have generally used the same PAs and criteria approved by the DoD P&T Committee for the TMOP. Under 32 CFR 199.21(k), prior authorizations now apply across all points of service. PA Forms and criteria may be found at: www.pec.ha.osd.mil/PA_Criteria_and_forms.htm

Prior Authorization Medications

Phosphodiesterase-5 (PDE-5) Inhibitors – sildenafil (Viagra®), tadalafil (Cialis®), vardenafil (Levitra®)

A PA and quantity limit for sildenafil was put into place in mail order in Aug 1999, based on Health Affairs Policy 98-040, Practice Guidelines for the Evaluation of Patients Requesting Sildenafil (Viagra™) for the Treatment of Male Impotence, released 6 Aug 1998. Vardenafil was included in the PA program in Nov 2003 and tadalafil in Feb 2004. TMA has determined that provisions of the sildenafil policy apply to these new PDE-5 inhibitors.

Among other provisions, the policy requires that

- PDE-5 inhibitors will not be a formulary item for Military Treatment Facilities (MTFs), National Mail Order Pharmacy (NMOP, the previous mail order program), and for Managed Care Support Contractor retail networks (now the TRICARE Retail Pharmacy program).
- Physicians treating patients with erectile dysfunction may special order PDE-5 inhibitors when the results of their evaluation indicate the medication as the most optimal regimen for the patient. MTFs will not fill special orders from non-network civilian providers unless there is proof of compliance with the prescribing guidance contained in the Health Affairs Policy 98-040.
- Only 6 tablets may be dispensed per month. "Lost", "stolen", or "destroyed" tablets will not be replaced. Prescriptions filled through Standard CHAMPUS will be reimbursed for only 6 tablets per month and must be accompanied by proof of compliance with clinical guidelines.

The accompanying prescribing guidelines include establishing that the erectile dysfunction is organic in origin.

The PDE-5 inhibitors are currently non-formulary at TMOP, but available if PA criteria are met. The quantity limit of 6 per 30 days has been implemented across the class – that is, a patient may obtain only 6 tablets of any combination of these medications per 30 days in the retail network, and only 18 tablets of any combination of these medications per 90 days in mail order.

Existing PA Criteria for PDE-5 Inhibitors for the Treatment of Erectile Dysfunction

- Coverage not provided for female sexual dysfunction, males under 18 years of age, patients receiving any form of nitrate therapy, or psychogenic erectile dysfunction.
- Coverage provided for organic erectile dysfunction, erectile dysfunction with an organic component, or drug-induced erectile dysfunction where the causative drug cannot be altered or discontinued. Approval is good for 12 months.
- *Note:* PDE-5 inhibitors are subject to a cumulative quantity limit of 6 tablets per 30 days in the retail network or 18 tablets per 90 days in the TMOP.

Revised PA Criteria for PDE-5 Inhibitors for the Treatment of Erectile Dysfunction if the ASD(HA) concurs in the modification or rescission of HA Policy 98-040

- Coverage not provided for female sexual dysfunction, males under 18 years of age, or psychogenic erectile dysfunction.
- Coverage provided for organic erectile dysfunction, erectile dysfunction with an organic component, or drug-induced erectile dysfunction where the causative drug cannot be altered or discontinued. Approval is good for 12 months.
- *Note:* Prior authorization is required for coverage of PDE-5 inhibitors for erectile dysfunction for male patients 18 to 49 years of age. Prior authorization is not required for male patients 50 years of age and older.
- *Note:* PDE-5 inhibitors are subject to a cumulative quantity limit of 6 tablets per 30 days in the retail network or 18 tablets per 90 days in the TMOP.

Etanercept (Enbrel®)

The PA for etanercept was approved by the DoD P&T Committee in May 1999 and implemented in Aug 1999. The rationale for the PA was high cost and potential for inappropriate use.

A quantity limit of 8 vials (a 4-week supply) was initially set for the mail order program, then changed to a 6-week supply (12 vials) in Aug 1999 to allow time for refills to be ordered and received by patients. A quantity limit of 8 vials (a four-week supply) was established in retail.

Existing PA Criteria for Etanercept

- Coverage provided for the treatment of
    - Moderately to severely active rheumatoid arthritis
    - Active psoriatic arthritis
    - Active ankylosing spondylitis
    - Juvenile rheumatoid arthritis when the patient has an inadequate response to at least one disease-modifying antirheumatic drug (DMARD).
- Coverage NOT provided for concomitant use with adalimumab (Humira), anakinra (Kineret), or infliximab (Remicade).
- *Note:* Etanercept is subject to a quantity limit of 8 vials (four-week supply) in retail and 12 vials (six-week supply) in mail order.

Note: Criteria for etanercept and the other biologics have primarily been based on the FDA indications, which closely follow the available clinical evidence for these medications.

Revised PA Criteria for Etanercept

- Coverage provided for the treatment of:
    - Moderately to severely active rheumatoid arthritis
    - Active psoriatic arthritis
    - Active ankylosing spondylitis
    - Juvenile rheumatoid arthritis when the patient has an inadequate response to at least one DMARD
    - Chronic moderate to severe plaque psoriasis when the patient has tried and failed traditional therapy, such as phototherapy (e.g., UVB, PUVA) or systemic therapy (e.g., methotrexate, acitretin or cyclosporine) OR is not a candidate for phototherapy or systemic therapy
- Coverage NOT provided for concomitant use with adalimumab (Humira), anakinra (Kineret), or infliximab (Remicade).
- *Note:* Etanercept is subject to a quantity limit of a four-week supply in retail and a six-week supply in mail order (based on instructions for use on the prescription).

Adalimumab (Humira®)

A PA for adalimumab was implemented in mail order in March 2003. The rationale for the PA was high cost, potential for inappropriate use, and the existence of a PA for similar agents.

PA Criteria for Adalimumab

- Coverage provided for the treatment of moderately to severely active rheumatoid arthritis in patients 18 years of age or older when the patient has had an inadequate response to at least one disease-modifying antirheumatic drug (DMARD).
- Coverage NOT provided for concomitant use with anakinra (Kineret), etanercept (Enbrel), or infliximab (Remicade).
- *Note:* Adalimumab is subject to a quantity limit of a 4-week supply in retail and a 6-week supply in mail order.

Anakinra (Kineret®)

History – A PA for anakinra was implemented in mail order in Feb 2002. The rationale for the PA was high cost, potential for inappropriate use, and the existence of a PA for a similar agent.

A quantity limit of a 6-week supply (6 packages of 7 syringes) at mail order was changed to a 8-week supply (2 packages of 28 syringes) at the April 2004 DoD P&T Committee meeting because of a packaging change by the manufacturer. The quantity limit is 28 syringes (1 package) in retail.

PA Criteria for Anakinra

- Coverage provided for the treatment of moderately to severely active rheumatoid arthritis in patients 18 years of age or older when the patient has had an inadequate response to at least one disease-modifying antirheumatic drug (DMARD).
- Coverage NOT provided for concomitant use with adalimumab (Humira), etanercept (Enbrel) or infliximab (Remicade).
- *Note:* Anakinra is subject to a quantity limit of 28 syringes (4-week supply) in retail and 56 syringes (8-week supply) in mail order.

Efalizumab (Raptiva®)

A PA for efalizumab was implemented in mail order in Feb 2004. The rationale for the PA was high cost, potential for inappropriate use, and the existence of a PA for similar agents.

PA Criteria for Efalizumab

- Coverage provided for adults (age ≥ 18 years) who meet all the following criteria:
    - Chronic moderate to severe plaque psoriasis, defined as a minimum body surface area involvement of 10% or a body surface area involvement of less than 10%, but in critical areas (e.g., palms, soles, or face) and interfering with day-to-day activities;

    AND

    - Have tried and failed traditional therapy, such as phototherapy (e.g., UVB, PUVA) or systemic therapy (e.g., methotrexate, acitretin, or cyclosporine), OR are not candidates for phototherapy or systemic therapy;

    AND

    - A dermatologist recommends treatment with efalizumab.
- Coverage NOT provided for immunocompromised patients or those receiving immunosuppressive agents, children (age < 18 years), or patients with psoriatic arthritis without plaque psoriasis.
- *Note:* No special quantity limits

Injectable gonadotropins (fertility agents)- follitropin alfa, follitropin beta, menotropins, urofollitropin (Brand names include: Gonal-F®, Follistim®, Humegon®, Pergonal®, Repronex®, Fertinex®, Bravelle®)

The Code of Federal Regulations (CFR) excludes coverage by TRICARE of services and supplies used in conjunction with noncoital reproductive technologies (e.g., *in vitro* fertilization). Compliance with the CFR in regard to fertility agents dispensed by the National Mail Order Pharmacy (NMOP) program was discussed by the DoD P&T Committee as early as Feb 1999, although at that time the NMOP contract did not provide for a prior authorization mechanism. Managed Care Support Contractors were responsible for implementing this policy in their networks, but the NMOP lacked any mechanism to ascertain whether the medications were being used for coital or noncoital reproduction. In Feb 2000, the Committee concluded that a prior authorization should be established in order to comply with TRICARE policy.

PA Criteria for Injectable Gonadotropins

- Coverage is NOT provided if the fertility agent is being prescribed for use in conjunction with a noncoital reproductive technology, including but not limited to artificial insemination, in vitro fertilization, or gamete intrafallopian transfer.
- *Note*: the PA form makes allowances for male patients being treated with injectable gonadotropins (e.g., for induction of spermatogenesis).
- *Note:* Quantity limits (3600 IU per 30 days, with no refills) are also in effect for all the injectable gonadotropins. The "no refills" provision means that patients must submit a new prescription for each cycle of therapy, although the prior authorization is good for a year.

Antifungals for onychomycosis – ciclopirox topical solution (Penlac Nail Lacquer®), terbinafine tablets (Lamisil®), and itraconazole capsules (Sporanox®)

The PA was implemented in mail order in July 2000 for terbinafine and itraconazole, with ciclopirox topical solution added in May 2001.

Rationale for PA

Because of the potential side effects, cost, and requirements for liver function testing associated with systemic antifungal therapy for onychomycosis, verifying the presence of a fungal infection prior to treatment is good clinical practice. A study published in CUTIS (1999;64:407-10) showed that as many as 35% of patients empirically diagnosed with onychomycosis did not have a fungal infection. The FDA recommends 1) definitive diagnosis of a fungal infection, 2) pretreatment lab tests, and 3) avoidance of these drugs in patients with acute or chronic liver disease. Although ciclopirox is applied topically, the prolonged course of therapy (up to 48 weeks) supports verification of an active fungal infection prior to beginning treatment.

Because it takes time for the nail to grow out following a course of systemic treatment for onychomycosis, re-treatment with systemic agents prior to 6 months is typically not necessary. *Each course of treatment with terbinafine, itraconazole, or ciclopirox for the treatment of onychomycosis requires confirmation of an active fungal infection and a separate prior authorization form.*

Criteria for Antifungals for Onychomycosis

- Coverage NOT provided for treatment of onychomycosis not confirmed by a microbiological or histological test [KOH preparation, periodic acid Schiff stain (PAS stain), or culture].
- Coverage IS provided for treatment of onychomycosis confirmed by a microbiological or histological test [KOH preparation, periodic acid Schiff stain (PAS stain), or culture].
- For terbinafine and itraconazole, coverage is approved for 6 weeks for treatment of fingernail onychomycosis and 12 weeks for treatment of toenail onychomycosis. For ciclopirox, coverage is approved for up to 48 weeks for both fingernail and toenail onychomycosis.

- Each course of treatment for onychomycosis requires confirmation of an active fungal infection and a separate prior authorization form.
- For treatment of fungal infection other than onychomycosis, coverage is approved for 12 months.
- *Note:* the PA does not apply to other formulations of ciclopirox (e.g., cream, gel, topical suspension, or shampoo) or itraconazole (e.g., injection or oral solution), since these formulations are not typically used for the treatment of onychomycosis.

Growth hormone (somatropin & somatrem)
(Brand names include: Humatrope®, Genotropin®, Norditropin®, Norditropin Depot®, Saizen®, Serostim®, Protropin®, Tev-Tropin®, Nutropin®, Nutropin AQ®, and Zorbtive®)

The DoD P&T Committee evaluated a PA for growth hormone in Feb 2004, prompted by FDA approval of a growth hormone product (Humatrope) for the treatment of non-growth hormone dependent short stature, also known as idiopathic short stature (ISS). Treatment of ISS is not considered medically necessary, and thus is not covered by TRICARE. In April 2004, the Committee approved PA criteria (developed with the assistance of a panel of MTF pediatric and adult endocrinologists) for the use of growth hormone in adults and in children. The rationale for the PA was potential for inappropriate use, TRICARE coverage rules.

A PA for growth hormone products was implemented in mail order and the retail network as of 1 June 2004, with the implementation of the TRRx program. Some or all MCSCs may already have PAs in place for growth hormone. The growth hormone PA is currently in place for new patient starts only (patients presenting a new growth hormone prescription at a retail network pharmacy or the TMOP for whom there was no prescription fill for growth hormone in the preceding 180 days). The DoD P&T Committee recommended that patients who are currently receiving growth hormone in the TMOP and retail network (based on use within the last 180 days) should be required to fulfill PA requirements within 180 days after being notified about the existence of the PA.

PA Criteria for Growth Hormone

Coverage provided for:

- Growth hormone deficiency in children and adults as a result of pituitary disease, hypothalamic disease, surgery or radiation therapy
- Chronic renal insufficiency before renal transplantation with associated short stature
- Other known renal indications: autorecessive polycystic kidney disease, cystinosis and hypophosphatemic rickets in the pediatric population
- Short stature in patients with Turner Syndrome or Prader-Willi syndrome
- Infants born small for gestational age that have not reached age appropriate height by 24 months of age
- Human immunodeficiency virus-associated wasting in adults

Coverage NOT provided for:

- Idiopathic short stature
- Depression
- Aging
- Obesity

Appendix B - Quantity Limits in the TRICARE Mail Order Pharmacy and TRICARE Retail Pharmacy Programs

The Department of Defense Pharmacy and Therapeutics (P&T) Committee has implemented quantity limits on specific medications in the TRICARE Mail Order Pharmacy (TMOP) as well as the retail network pharmacies, based on Food and Drug Administration (FDA) recommendations for dosing. Quantity limits are a common practice in commercial health plans to help ensure beneficiaries receive the proper dose and recommended duration of therapy for their disease state to achieve the optimal outcome of their treated condition, while minimizing potential for adverse events, inappropriate therapy, and wastage.

Special Note about the TRICARE Retail Pharmacy (TRRx) Program: As of June 1, 2004, responsibility for DoD's TRICARE retail pharmacy network passed to a single contractor, Express-Scripts, Inc. (ESI), consolidating all of DoD's regional retail pharmacy contracts into a single national contract. The retail pharmacy quantity limits listed on this page continue to apply under the new contract.

Days Supply of Medication

The TMOP generally dispenses no more than a 90-day supply of medication.

Retail pharmacies generally dispense no more than a 30-day supply of medication. If a patient desires to obtain more than a 30-day supply at a retail pharmacy, he/she must pay an additional cost share for each additional 30-day supply increment, up to a 90-day supply (3 cost shares).

Quantity Limits

The quantity of medication dispensed to a patient is limited to **the lesser of**: (1) the amount of medication expected to be used in a 90-day period (TMOP) or a 30-day period (retail pharmacy network) based on the directions for use on the prescription, or (2) the quantity limit identified in the table below. The amount of medication obtained by a patient from other Military Health System pharmacy points of service will be taken into account in the application of these quantity limits.

Refills

If the amount dispensed is reduced because of an established quantity limit, refills will be authorized unless the item is designated “no refills allowed” in the table below. For example, the TMOP quantity limit for adalimumab (Humira) is six 40-mg prefilled syringes per six-week period. Therefore, if the TMOP receives a prescription written for 18 prefilled syringes of 40 mg adalimumab (Humira) injection with no refills, the prescription will be filled with 6 syringes, the patient will be charged the applicable cost share, and two refills (of 6 syringes each) will be authorized. The patient will be authorized to obtain a refill (for another 6 syringes) 6 weeks after the original prescription was filled, and will be charged the applicable cost share.

Note: Drugs are listed by generic name. Brand name(s) are supplied in parentheses for convenience only. Quantity limits apply to both brand name and generic versions of listed medications.

Quantity limits developed by the DoD P&T Committee may be superceded by applicable federal and/or state laws.

Drug	TMOP Limits	Retail Pharmacy Limits
Antibiotics		
Azithromycin (Zithromax) 250mg tablets	10 tablets per 30 days	10 tablets per 30 days
Azithromycin (Zithromax) 600mg tablets	24 tablets per 90 days	8 tablets per 30 days
Antiemetics		
Aprepitant (Emend) capsules in convenience packs (one 125 mg capsule and two 80 mg capsules)	6 packs per 90 days	2 packs per 30 days
Aprepitant (Emend) 80 mg capsules	12 capsules per 90 days	4 capsules per 30 days
Aprepitant (Emend) 125 mg capsules	6 capsules per 90 days	2 capsules per 30 days
Granisetron (Kytril) 1mg tablets	24 tablets per 90 days	8 tablets per 30 days
Ondansetron (Zofran) (Zofran; Zofran ODT) 4 and 8 mg tablets and orally disintegrating tablets	45 tablets per 90 days	15 tablets per 30 days
Dolasetron (Anzemet) 50 and 100 mg tablets	15 tablets per 90 days	5 tablets per 30 days
Antifungals		
Fluconazole (Diflucan) 150 mg oral tablets	3 tablets per 90 days	1 Tablet per 30 days
Antimigraine Drugs		
Almotriptan (Axert) 6.25 and 12.5 mg tablets	36 tablets per 90 days	12 tablets per 30 days
Dihydroergotamine (Migranal) 1 mL ampules for nasal spray	90 ampules per 90 days	30 ampules per 30 days
Dihydroergotamine 1 mg/ml injection	90 ampules per 90 days (9 boxes of 10 ampules)	30 ampules per 30 days (3 boxes)
Eletriptan (Relpax)	36 tablets per 90 days	12 tablets per 30 days
Frovatriptan (Frova) 2.5 mg tablets	27 tablets per 90 days	9 tablets per 30 days
Naratriptan (Amerge) 1 and 2.5 mg tablets	27 tablets per 90 days	9 tablets per 30 days
Rizatriptan (Maxalt; Maxalt MLT) 5 and 10 mg tablets and orally-disintegrating tablets	36 tablets per 90 days	12 tablets per 30 days
Sumatriptan (Imitrex) 25, 50 mg tablets	54 tablets per 90 days	18 tablets per 30 days
Sumatriptan (Imitrex) 100 mg tablets	27 tablets per 90 days	9 tablets per 30 days
Sumatriptan (Imitrex) injection 6mg/0.5mL autoinjector (syringes)	24 syringes per 90 days	8 syringes per 30 days
Sumatriptan (Imitrex) injection 6mg/0.5mL vials	24 vials per 90 days	8 vials per 30 days
Sumatriptan (Imitrex) 5mg/100 µL and 20 mg/100 µL nasal spray	18 unit dose nasal sprays per 90 days	6 unit dose nasal sprays per 30 days
Zolmitriptan nasal spray 5 mg/100 µL nasal spray	36 unit dose nasal sprays per 90 days	12 unit dose nasal sprays per 30 days
Zolmitriptan (Zomig; Zomig-ZMT) 2.5 and 5 mg tablets and orally-disintegrating tablets	24 tablets per 90 days	8 tablets per 30 days

Drug	TMOP Limits	Retail Pharmacy Limits
Controlled Substances		
Schedule II drugs	NO refills per federal law; state law may impose additional restrictions	
Schedule III and IV drugs	Per federal law, prescriptions may not be filled or refilled for more than 6 months after the date of the prescription or refilled more than 5 times. State law may impose additional restrictions.	
Testosterone buccal system mucoadhesive (Striant)	180 systems per 90 days (3 cartons of 60 systems)	60 systems per 30 days (1 carton of 60 systems)
Fertility Agents		
Follitroprin alpha for injection (Gonal-F) 37.5 IU ampules	96 ampules (3,600 IU) per 30 days - no refills	96 ampules (3,600 IU) per 30 days - no refills
Follitroprin alpha for injection (Gonal-F) 75 IU ampules	48 ampules (3,600 IU) per 30 days - no refills	48 ampules (3,600 IU) per 30 days - no refills
Follitroprin alpha for injection (Gonal-F) 150 IU ampules	24 ampules (3,600 IU) per 30 days - no refills	24 ampules (3,600 IU) per 30 days - no refills
Follitroprin alpha for injection (Gonal-F) 600 IU/mL kit	6 kits (3,600 IU) per 30 days - no refills	6 kits (3,600 IU) per 30 days - no refills
Follitroprin beta for injection (Follistim) 75 IU vials	48 vials (3,600) IU per 30 days - no refills	48 vials (3,600 IU) per 30 days - no refills
Follitropin beta for injection (Follistim AQ) 300 IU vials	12 cartridges (3,600 IU) per 30 days - no refills	12 cartridges (3,600 IU) per 30 days - no refills
Follitropin beta for injection (Follistim AQ) 600 IU vials	6 cartridges (3,600 IU) per 30 days - no refills	6 cartridges (3,600 IU) per 30 days - no refills
Menotropins for injection (Humegon) 75 IU ampules	48 ampules (3,600 IU) per 30 days - no refills	48 ampules (3,600 IU) per 30 days - no refills
Menotropins for injection (Humegon) 150 IU ampules	24 ampules (3,600 IU) per 30 days - no refills	24 ampules (3,600 IU) per 30 days - no refills
Menotropins for injection (Pergonal) 75 IU ampules	48 ampules (3,600 IU) per 30 days - no refills	48 ampules (3,600 IU) per 30 days - no refills
Menotropins for injection (Pergonal) 150 IU ampules	24 ampules (3,600 IU) per 30 days - no refills	24 ampules (3,600 IU) per 30 days - no refills
Menotropins for injection (Repronex) 75 IU vials	48 vials (3,600) IU per 30 days - no refills	48 vials (3,600 IU) per 30 days - no refills
Urofollitropin for injection (Fertinex) 75 IU ampules	48 ampules (3,600 IU) per 30 days - no refills	48 ampules (3,600 IU) per 30 days - no refills
Urofollitropin for injection (Fertinex) 150 IU ampules	24 ampules (3,600 IU) per 30 days - no refills	24 ampules (3,600 IU) per 30 days - no refills
Urofollitropin for injection (Bravelle) 75 IU ampules	48 ampules (3,600 IU) per 30 days - no refills	48 ampules (3,600 IU) per 30 days - no refills
Impotence Agents		
Drug	TMOP Limits	Retail Pharmacy Limits
Alprostadil injection (Caverject, Edex) 5, 10, 20, and 40 mcg syringes (kits) and vials	18 syringes or vials per 90 days	6 syringes or vials per 30 days
Alprostadil intraurethral pellet (Muse) 125, 250, 500, and 1000 mcg pellets	18 pellets per 90 days	6 pellets per 30 days

Drug	TMOP Limits	Retail Pharmacy Limits
Oral phosphodiesterase-5 (PDE-5) inhibitors Sildenafil (Viagra) 25-, 50-, and 100-mg tablets Tadalafil (Cialis) 5-, 10-, and 20-mg tablets Vardenafil (Levitra) 2.5-, 5-, 10-, and 20-mg tablets	18 tablets per 90 days Quantity limit applies collectively to all strengths of sildenafil, tadalafil, and vardenafil. No more than 18 tablets of any combination of these medications per 90-day supply will be dispensed in the TMOP.	6 tablets per 30 days Quantity limit applies collectively to all strengths of sildenafil, tadalafil, and vardenafil.No more than 6 tablets per 30-day supply of any combination of these medications will be dispensed in the retail network
Miscellaneous		
All syringes & needles	600 syringes and/or needles per 90 days	200 syringes and/or needles per 30 days
Adalimumab (Humira) 40 mg prefilled syringes	6 syringes per 42 days (6 weeks) (3 packages of 2 syringes)	4 syringes per 28 days (4 weeks) (2 packages of 6 syringes)
Anakinra (Kineret) 100 mg/0.67 mL single use prefilled syringes	56 syringes per 56 days (8 weeks) (2 packages of 28 syringes)	28 syringes per 28 days (4 weeks) (1 package of 28 syringes)
Glucose test strips (includes blood and urine test strips)	600 strips per 90 days	200 strips per 30 days
Butorphanol (Stadol) metered dose nasal spray 2.5 mL bottles	15mL per 45 days (6 bottles)	10mL per 30 days (4 bottles)
Dornase alpha (Pulmozyme) inhalant solution 2.5 mL ampule	900 mL per 90 days (360 ampules)	300mL per 30 days (120 ampules)
Enfuvirtide (Fuzeon) injection kit	2 kits (60-day supply)	1 kit (30-day supply)
Etanercept (Enbrel) injection 25mg vial	6 weeks supply based on instructions for use on the prescription	4 weeks supply based on instructions for use on the prescription
Fluoxetine 90 mg capsule (Prozac Weekly)	12 capsules per 90 days (3 blister packs)	4 capsules per 30 days (1 blister pack)
Gefitinib tablets (Iressa)	45 tablets per 45 days	30 tablets per 30 days
Imitinab capsules (Gleevec)	45 days supply	general rule applies (30 days supply)
Ketorolac (Toradol) 10mg tablets	20 tablets (5 day supply) per 30 days	20 tablets (5 day supply) per 30 days
Ketorolac (Toradol) injection IV or IM 15mg/mL - 1mL TUBEX® or vial	Not available at TMOP	40 TUBEX® units or vials per 30 days (600 mg - 5 day supply)
Ketorolac (Toradol) injection IV or IM 30mg/mL 1mL TUBEX® or vial	Not available at TMOP	20 TUBEX® units or vials per 30 days (600 mg - 5 day supply)
Ketorolac (Toradol) injection IM 30mg/mL 2 mL (60 mg) TUBEX® or vial	Not available at TMOP	10 TUBEX® units or vials per 30 days (600 mg - 5 day supply)
PEG-filgrastim (Neulasta) 6 mg/0.6 mL injection	1.2 mL per 45 days (2 syringes)	0.6 mL per 21 days (1 syringe)
Tramadol (Ultram) 50 mg tablets; tramadol / acetaminophen (Ultracet) 37.5/325 mg tablets	720 tablets per 90 days	240 tablets per 30 days
Nasal Inhalers		
Beclomethasone (Beconase, Vancenase) 42 mcg nasal inhaler	100.8 gm per 90 days (15 6.7-gm inhalers or 6 16.8-gm inhalers)	33.5 gm per 30 days (5 6.7-gm inhalers or 2 16.8-gm inhalers)

Drug	TMOP Limits	Retail Pharmacy Limits
Beclomethasone AQ (Beconase AQ, Vancenase AQ) nasal inhaler 42 mcg	150 gm per 90 days (6 25-gm inhalers)	50 gm per 30 days (2 25-gm inhalers)
Beclomethasone AQ (Vancenase AQ) nasal inhaler 84 mcg	57 gm per 90 days (3 19-gm inhalers)	19 gm per 30 days (1 19-gm inhaler)
Budesonide (Rhinocort) 32mcg nasal inhaler	42 gm per 90 days (6 7-gm inhalers)	14 gm per 30 days (2 7-gm inhalers)
Budesonide AQ (Rhinocort AQ) 32mcg nasal spray	30 mL per 90 days (3 10-mL inhalers)	10 mL per 30 days (1 10-mL inhaler)
Flunisolide (Nasalide) nasal solution 0.025%	225 mL per 90 days (9 25-mL inhalers)	75 mL per 30 days (3 25-mL inhalers)
Fluticasone (Flonase) 0.05% nasal spray	48 gm per 90 days (3 16-gm inhalers)	16 gm per 30 days (1 16-gm inhaler)
Ipratropium bromide (Atrovent) 0.03% and 0.06% nasal spray	90 mL per 90 days (3 30-mL inhalers or 6 15-mL inhalers)	30 mL per 30 days (1 30-mL inhaler or 2 15-mL inhalers)
Mometasone (Nasonex) nasal inhaler 50mcg	51 gm per 90 days (3 17-gm inhalers)	17 gm per 30 days (1 17-gm inhaler)
Triamcinolone AQ (Nasacort AQ) 55mcg nasal spray	99 gm per 90 days (6 16.5-gm inhalers)	33 gm per 30 days (2 16.5-gm inhalers)
Triamcinolone (Nasacort) 55mcg nasal spray	90 gm per 90 days (9 10-gm inhalers)	30 gm per 30 days (3 10-gm inhalers)
Triamcinolone (Tri-nasal) 50 mcg nasal spray	90 mL per 90 days (6 15-mL inhalers)	30 mL per 30 days (2 15-mL inhalers)
Oral Inhalers and Inhalant Solutions		
Albuterol (AccuNeb) inhalant solution 0.63mg/3mL and 1.25mg/3mL	1650mL per 90 days (22 boxes of 25 = 550 nebules)	600 mL per 30 days (8 boxes of 25 = 200 nebules)
Albuterol (Proventil) 0.083% inhalant solution 3 mL	1650 mL per 90 days (22 boxes of 25 = 550 nebules)	600 mL per 30 days (8 boxes of 25 = 200 nebules)
Albuterol (Proventil) 0.5% inhalant solution 20 mL	180 mL (9 bottles) per 90 days	60 mL (3 bottles) per 30 days
Albuterol (Proventil) 90mcg metered dose inhaler	102 gm per 90 days (6 17-gm inhalers)	34 gm per 30 days (2 17-gm inhalers)
Albuterol HFA (Proventil HFA, Ventolin HFA) 90 mcg	108 gm per 90 days (6 18-gm inhalers or 16 6.7-gm inhalers)	36 gm per 30 days (2 18-gm inhalers or 5 6.7-gm inhalers)
Albuterol sulfate 3 mg / ipratropium bromide 0.5 mg per 3 mL inhalent solution (DuoNeb)	1620 mL per 90 days (540 vials)	540 mL per 30 days (180 vials)
Beclomethasone 42 mcg (Beclovent) oral inhaler	160.8 gm per 90 days (24 6.7-gm inhalers or 9 16.8-gm inhalers)	53.6 gm per 30 days (8 6.7-gm inhalers or 3 16.8-gm inhalers)
Beclomethasone 84 mcg (Vanceril DS) oral inhaler	129.6 gm per 90 days (24 5.4-gm inhalers or 9 12.2-gm inhalers)	43.2 gm per 30 days (8 5.4-gm inhalers or 3 12.2-gm inhalers)
Beclomethasone dipropionate HFA 40 mcg inhalation aerosol (QVar)	87.6 gm per 90 days (12 inhalers)	29.2 gm per 30 days (4 inhalers)

Drug	TMOP Limits	Retail Pharmacy Limits
Beclomethasone dipropionate HFA 80 mcg inhalation aerosol (QVar)	43.8 gm per 90 days (6 inhalers)	33.6 gm per 30 days (2 inhalers)
Bitolterol (Tornalate) 0.8% oral inhaler	90 mL per 90 days (6 inhalers)	30 mL per 30 days (2 inhalers)
Bitolterol (Tornalate) inhalant solution 0.2%	720 mL per 90 days (24 30-mL bottles or 12 60-mL bottles)	240 mL per 30 days (8 30-mL bottles or 4 60-mL bottles)
Budesonide (Pulmicort) oral inhaler	6 inhalers per 90 days	2 inhalers per 30 days
Budesonide 0.25 mg Inhalation Suspension (Pulmicort Respules®)	720 mL per 90 days (12 boxes of 30 Respules®)	240 mL per 30 days (4 boxes of 30 Respules®)
Budesonide 0.5 mg Inhalation Suspension (Pulmicort Respules®)	360 mL per 90 days (6 boxes of 30 Respules®)	120 mL per 30 days (2 boxes of 30 Respules®)
Cromolyn sodium (Intal) oral inhaler 800mcg	85.2 gm per 90 days (9 8.1-gm inhalers or 6 14.2 gm inhalers)	28.4 gm per 30 days (3 8.1-gm inhalers or 2 14.2-gm inhalers)
Cromolyn sodium (Intal) nebulizing solution 20 mg/ 2 mL unit dose ampules	1080 mL per 90 days (9 boxes = 540 ampules)	360 mL per 30 days (3 boxes = 180 ampules)
Flunisolide (Aerobid; Aerobid-M) oral inhaler 250 mcg	63 gm per 90 days (9 inhalers)	21 gm per 30 days (3 inhalers)
Fluticasone (Flovent) 44-, 110-, and 200-mcg oral inhalers	94.8 gm per 90 days (12 7.9-gm inhalers or 6 13-gm inhalers)	31.6 gm per 30 days (4 7.9-gm inhalers or 2 13-gm inhalers)
Fluticasone (Flovent) 50-, 100-, and 250 -mcg Rotadisks®	720 doses per 90 days (12 boxes of 60 Rotadisks®)	240 doses per 30 days (4 boxes of 60 Rotadisks®)
Fluticasone / salmeterol (Advair) powder for inhalation 100 mcg/50 mcg; 250 mcg/50 mcg; and 500 mcg/50 mcg	180 doses per 90 days (3 inhalers)	60 doses per 30 days (1 inhaler)
Formoterol fumarate (Foradil) powder for inhalation 12 mcg	180 doses per 90 days (3 inhalers)	60 doses per 30 days (1 inhaler)
Ipratropium (Atrovent) 0.02% inhalant solution (2.5mL unit dose ampules)	1350 mL per 90 days (21 boxes of 25 ampules [525 ampules] or 18 boxes of 30 ampules [540 ampules] or 9 boxes of 60 ampules [540 ampules])	450 mL per 30 days (7 boxes of 25 ampules [175 ampules] or 6 boxes of 30 ampules [180 ampules] or 3 boxes of 60 ampules [180 ampules]
Ipratropium (Atrovent) oral inhaler 18 mcg	89 gm per 90 days (6 14.7-gm inhalers)	30 gm per 30 days (2 14.7-gm inhalers)
Levalbuterol (Xopenex) inhalant solution 0.63/3 mL or 1.25 mg/3mL ampules	1080 mL per 90 days (15 boxes of 24 ampules [360 ampules] or 4 boxes of 96 ampules [384 ampules])	360 mL per 30 days (5 boxes of 24 ampules [120 ampules] or 2 boxes of 96 ampules [192 ampules])
Metaproterenol (Alupent) inhalant solution 0.4% or 0.6% 2.5mL unit dose ampules	1250 mL per 90 days (18 boxes of 25 ampules [450 ampules] or 5 boxes of 100 ampules [500 ampules])	500 mL per 30 days (6 boxes of 25 ampules [150 ampules] or 2 boxes of 100 ampules [200 ampules])
Metaproterenol (Alupent) inhalant solution 5% 10mL	180 mL per 90 days (18 10-mL bottles or 6 30-mL bottles)	60 mL per 30 days (6 10-mL bottles or 2 30-mL bottles)

Drug	TMOP Limits	Retail Pharmacy Limits
Metaproterenol (Alupent) oral inhaler 650mcg	84 gm per 90 days (12 7-gm inhalers or 6 14-gm inhalers)	28 gm per 30 days (4 7-gm inhalers or 2 14-gm inhalers)
Nedocromil (Tilade) oral inhaler	145.8 gm per 90 days (9 16.2-gm inhalers)	48.6 gm per 30 days (3 16.2-gm inhalers)
Pirbuterol (Maxair) oral Autohaler®	42 gm per 90 days (3 14-gm inhalers or 15 2.8-gm inhalers)	14 gm per 30 days (1 14-gm inhaler or 5 2.8-gm inhalers)
Pirbuterol (Maxair) oral inhaler	153.6 gm per 90 days (6 25.6-gm inhalers)	51.2 gm per 30 days (2 25.6-gm inhalers)
Salmeterol (Serevent DISKUS®) 50mcg oral inhalation powder Please note: production of salmeterol metered dose oral inhalers has been discontinued. The salmeterol dry powder inhaler (Serevent Diskus) is now the only formulation available. Click here for additional information.	180 doses (blister packs) per 90 days (3 boxes of 60 blister packs)	60 doses (blister packs) per 30 days (1 box of 60 blister packs)
Tiotropium bromide (Spiriva HandiHaler) inhalation powder	90 capsules for inhalation per 90 days (3 packages of 30 caps)	30 capsules for inhalation per 30 days (1 package of 30 caps)
Triamcinolone (Azmacort) oral inhaler 20gm	120 gm per 90 days (6 20-gm inhalers)	40 gm per 30 days (2 20-gm inhalers)
Topicals		
Imiquimod (Aldara) 5% cream	36 single use packets per 90 days (3 boxes of 12 packets)	12 single use packets per 30 days (1 box of 12 packets)
Calcipotriene (Dovonex) 0.005% cream or ointment (30-, 60-, or 100-gm Tubes)	900 gm per 90 days	300 gm per 30 days
Calcipotriene (Dovonex) 0.005% solution	900 mL per 90 days (15 60-mL bottles)	300 mL per 30 days (5 60-mL bottles)
Alitretinoin (Panretin) 0.1% gel	180 gm per 90 days (3 60-gm tubes)	60 gm per 30 days (1 60-gm tube)
Becaplermin (Regranex) 0.01% gel (2-, 7.5- or 15-gm tubes)	45 gm per 90 days	15 gm per 30 days
Tazarotene (Tazorac) 0.05% or 0.1% gel (30- or 100-gm tubes)	300 gm per 90 days	100 gm per 30 days

Correction - The next meetings of the DoD P&T Committee have been changed to Tuesday 13 July and Wednesday 14 July, 2004.

Department of Defense Pharmacoeconomic Center

2421 Dickman Rd., Bldg. 1001, Rm. 310
Fort Sam Houston, TX 78234-5081

MCCS-GPE **20 APRIL 2004**

MEMORANDUM FOR: Executive Director, TRICARE Management Activity (TMA)

SUBJECT: Minutes of the Department of Defense (DoD) Pharmacy and Therapeutics (P&T) Committee Meeting

1. A meeting of the DoD P&T Committee convened at 0800 hours on 20 April 2004 at the DoD Pharmacoeconomic Center, Fort Sam Houston, Texas.

2. VOTING MEMBERS PRESENT

COL Daniel D. Remund, MS	DoD P& T Committee Co-chair
CAPT Terrance Egland, MC (via VTC)	DoD P& T Committee Co-chair
COL Mike Heath, MS (For MAJ Travis Watson)	Army
COL Joel Schmidt, MC	Army
COL Doreen Lounsbery, MC	Army
LtCol Gordon Wright Bates, Jr, MC	Air Force
Col Phil Samples, BSC	Air Force
CAPT Matt Nutaitis, MC	Navy
CDR Mark Richerson, MSC	Navy
CDR Patrick Marshall	Coast Guard
Rance Hutchings, Pharm.D. (For Dr. Trevor Rabie)	Uniformed Services Family Health Plans (USFHP)
Joe Canzolino	Department of Veterans Affairs

VOTING MEMBERS ABSENT

Col James E. Cox, Jr. MC	Air Force

OTHERS PRESENT

COL William Davies, MS, USA	DoD Pharmacy Program Director, TMA
CAPT Patricia Buss, MC, USN	Chief Medical Officer Representative, TMA
COL James Young, BSC, USAF	DoD Pharmacy Program Assistant Director, TMA
COL Kent Maneval, MS, USA	Joint Readiness Clinical Advisory Board
CDR Denise Graham, MSC, USN	DoD Pharmacoeconomic Center
CDR Ted Briski, MSC, USN (via TC)	DoD Pharmacoeconomic Center
CDR Don Nichols, MC, USN	DoD Pharmacoeconomic Center
LtCol Dave Bennett, BSC, USAF	DoD Pharmacoeconomic Center
LtCol Barb Roach, MC, USAF	DoD Pharmacoeconomic Center
CPT Jill Dacus, MC, USA	DoD Pharmacoeconomic Center
Dave Bretzke	DoD Pharmacoeconomic Center
Shana Trice	DoD Pharmacoeconomic Center
Eugene Moore	DoD Pharmacoeconomic Center
Angela Allerman	DoD Pharmacoeconomic Center
Elizabeth Hearin	DoD Pharmacoeconomic Center
Lisa LeGette	Express Scripts
Elaine Furmaga	Department of Veterans Affairs
Four pharmacists	Iraq Ministry of Health

3. **REVIEW MINUTES OF LAST MEETING** – The minutes from the last meeting were accepted as written.

4. **INTERIM/ADMINISTRATIVE DECISIONS** – None

5. **UNIFORM FORMULARY (UF) PROPOSED RULE** – COL William Davies, DoD Pharmacy Program Director, TMA, updated the Committee on the current status of the Uniform Formulary. The final Uniform Formulary Rule was published 1 Apr 2004. It is available at: http://a257.g.akamaitech.net/7/257/2422/14mar20010800/edocket.access.gpo.gov/2004/04-7129.htm.

6. **TRICARE RETAIL PHARMACY (TRRx) UPDATE –** Libby Hearin (PEC) updated the Committee on the status of the TRICARE Retail Pharmacy (TRRx) Program implementation. TRRx establishes a retail pharmacy network that will provide outpatient prescription services to TRICARE beneficiaries throughout the United States, Guam, Puerto Rico, and the U.S. Virgin Islands. Express-Scripts, Inc (ESI) is the contractor for TRRx. ESI is also the contractor for the TRICARE Mail Order Pharmacy (TMOP).

   Beneficiary and provider information concerning TRRx is currently available on the TRICARE Pharmacy site (www.tricare.osd.mil/pharmacy) and on ESI's site at www.express-scripts.com. ESI marketing materials include benefit guides, pharmacy information cards, and introductory letters with a list of network pharmacies closest to beneficiaries. Mail-outs to beneficiary households, TRICARE Service Centers, and placement on the TRICARE SMART site (www.tricare.osd.mil/smart) for MTFs begin 22 Apr 2004.

7. **BCF AND TRICARE MAIL ORDER PHARMACY (TMOP) FORMULARY ISSUES** – The Committee determined the TMOP formulary status, TMOP or retail network formulary restrictions (quantity limits or prior authorization), and Basic Core Formulary (BCF) status for two new drugs and one new combination product. The Committee also confirmed the status of two new formulations of existing products (see Appendix A).

7. **ENFUVIRTIDE (FUZEON)** – The manufacturer of enfuvirtide (Fuzeon) has discontinued the controlled distribution program for this product. Under the controlled distribution program, enfuvirtide was previously available in the retail network only through a specialty pharmacy (Chronimed) and was not available in the TMOP. MTFs could purchase enfuvirtide through a special arrangement with Chronimed, but were not able to use the prime vendor system to obtain the product.

   The manufacturer reports that shipping to wholesalers started 14 Apr 2004. The product is expected to be available through U.S. retail and specialty pharmacies staring 26 Apr 2004. MTFs should be able to order Fuzeon from wholesalers as of 26 Apr 2004. Additional information is available at www.pec.ha.osd.mil/Controlled_Distribution_Drugs.htm or from the manufacturer's website (www.fuzeon.com) or help line (1-877-438-9366).

   Enfuvirtide is approved for use in combination with other antiretroviral agents for the treatment of HIV-1 infection in treatment-experienced patients with evidence of HIV-1 replication despite ongoing antiretroviral therapy. It is given via subcutaneous injection twice daily and may be self-administered by the patient. The Committee will consider Fuzeon for addition to the TMOP Covered Injectables List as soon as it is clear that supplies of enfuvirtide are adequate and that the TMOP will have no difficulty obtaining the product.

9. **SERMORELIN (GEREF, SERONO)** – The Geref brand of sermorelin (growth hormone releasing hormone) has been withdrawn from the market. The diagnostic product (Geref Diagnostic) is still available. Since the therapeutic product is no longer available, the Committee removed sermorelin from the TMOP Covered Injectables List.

10. **KETOROLAC ORAL** – Currently, ketorolac (Toradol) tablets are available from the TMOP with a quantity limit of 5 days supply per 30 days. Express-Scripts does not typically make ketorolac tablets available through mail order plans, so they requested that the Committee consider discontinuing availability of ketorolac tablets at the TMOP. In the 6-month period from Oct 2003 to Mar 2004, the TMOP filled 41 prescriptions for ketorolac tablets, none of which exceeded 20 tablets (a 5-day supply at maximum recommended dosing). The Committee decided that since some patients do fill prescriptions for ketorolac tablets through the TMOP and since there is no indication that patients are receiving excessive quantities of ketorolac, ketorolac tablets will remain on the TMOP Formulary with the current quantity limits.

11. **QUININE** – Quinine has historically been used for nocturnal leg cramps, but this has never been an FDA-approved indication. In 1994-1995, the FDA halted the sale and distribution of OTC quinine sulfate for leg cramps due to its serious risks (Federal Register, 22 Aug 1994). In 1995, the FDA sent letters to manufacturers ordering a halt to the promotion of prescription quinine for leg cramps (FDA Consumer, 1995). In 1998, the FDA halted the sale and distribution of OTC quinine for malaria (Federal Register, 20 Mar 1998). In Feb 1999, the DoD P&T Committee excluded quinine from the National Mail Order Pharmacy (the

previous mail order program), based on the FDA's actions. Since a formulary does not exist in the retail network, the Committee could not take similar action in regard to the availability of quinine in the retail network. Quinine continues to be available in the retail network.

The only FDA-approved indication for quinine is as a prescription drug for the second-line treatment of malaria, but the vast majority of quinine prescriptions are most likely for treatment of leg cramps. Quinine is also available in food products and dietary supplements.

The Committee agreed that drugs available in the TMOP and the retail network should be consistent whenever reasonable and possible. The Committee considered three options:

- Make quinine available without formulary restriction in both TMOP & the retail network (TRRx).
- Subject quinine to formulary restrictions in both TMOP and TRRx.
- Maintain the status quo.

Background

Nocturnal leg cramps are a common problem in elderly patients. Nonpharmacological treatments (e.g., stretching, heat, correction of dehydration or electrolyte imbalances) are considered first-line therapies. Besides quinine, medications that have been used to treat nocturnal leg cramps include gabapentin, verapamil, muscle relaxants, vitamin E, magnesium, and B-complex vitamins.

Efficacy

Two systematic reviews of quinine for leg cramps support its efficacy for this condition:

- In 1995, Man-Son-Hing M et al (BMJ 1995; 310:13-7) reviewed six placebo-controlled cross-over trials including 107 patients, mostly elderly. Patients received 200-300mg quinine sulfate/day over 2- 4 weeks. Compared to placebo, quinine resulted in 8.83 fewer cramps over 4 weeks (95% CI 4.16 , 13.49) based on 5 trials in 82 pts, a relative risk reduction of 43% (95% CI 21%, 65%). There was a 27.5% reduction (95% CI 30.6%, 24.4%) in the number of nights with cramps, based on 2 trials in 51 pts. There was no statistically significant change in the severity or duration of cramps.
- In 1998, Man-Son-Hing M & Wells G, (J Gen Intern Med 1998; 13:600-6) published an updated meta-analysis including pooled individual patient data (combined n=659) from 8 randomized, double-blind, placebo-controlled trials (7 cross-over trials), 4 of which were unpublished. Patients taking quinine had 3.6 (95% CI 2.15 , 5.05) fewer leg cramps over 4 weeks compared to placebo, a relative risk reduction of 21% (95% CI 12% , 30%). Investigators concluded that while publication bias was present (almost all published studies reported higher efficacy than unpublished studies), quinine still appeared to be more effective than placebo in reducing the frequency of nocturnal leg cramps.

Safety/Tolerability

- The FDA's 1994-1995 regulatory actions were based on 157 reports of quinine-associated adverse drug reactions (1969 through mid-1992), 105 of which involved dosing within recommendations. The reports included 16 deaths and 40 hospitalizations.
- Adverse effects at doses used for leg cramps include dizziness, fever, nausea and vomiting, diarrhea, visual or auditory disturbances, and thrombocytopenia (rare but

potentially fatal). Quinine should NOT be used in pregnancy (Category X), should be used with caution in patients with renal failure, and should be avoided in patients with hepatic failure. Patients with a history of immune mediated thrombocytopenia or G-6-PD deficiency should not receive quinine.

- Brinker & Beitz (Am J Hematol 2002; 70:313-7) reported on a case series of thrombocytopenia associated with quinine. Of 397 adverse drug reactions for quinine reported to the FDA from 1974 – 2000, there were 141 reports of apparently isolated thrombocytopenia. After eliminating cases confounded by disease or drug therapy, investigators focused on 64 reports. The typical presentation of thrombocytopenia appeared to be rapid (median time-to-onset 7 days) and severe (hospitalization in 57 cases). Investigators suggested that clinicians evaluating patients with new-onset thrombocytopenia watch for quinine use, including food and dietary supplements.
- Kojouri et al (Ann Intern Med 2001;135:1047-51) reported that 11% of 132 consecutive cases of thrombotic thrombocytopenic purpura-hemolytic uremic syndrome (TTP-HUS) were associated with quinine. They commented that the toxicity appeared immune-mediated, with a sudden onset. Women may be more susceptible than men.
- Quinine has a long half-life, is protein-bound, and is metabolized by CYP450. It has several potentially dangerous drug-drug interactions, including elevation of digoxin levels and increased effect of anticoagulants.

Other Factors

Various criteria, guidelines, and recommendations from published reviews conclude that while quinine should not be used first-line, cautious use may be justified in patients with severe symptoms who have failed other treatments.

- The VA's nonformulary criteria for use (available at www.vapbm.org) recommend reserving use of quinine for nocturnal leg cramps for patients who have failed other modalities and who have severe symptoms requiring treatment. Patients should be advised of the potential for adverse drug reactions.
- Similar advice is provided by the UK National Health System's PRODIGY guidance, (http://www.prodigy.nhs.uk/guidance.asp?gt=Leg%20cramps) which recommends non-drug treatment first-line, with drug treatment only in people with regular cramps significantly affecting quality of life. The guidance suggests that clinicians monitor the risk-benefit ratio with quinine due to the potentially toxic effects.
- The April 2004 Pharmacist's Letter succinctly summarizes the dilemma, suggesting that pharmacists "help people understand pros and cons and decide for themselves…"

Quinine Utilization

- A total of 28,655 DoD beneficiaries received at least one prescription for quinine at MTFs or retail pharmacies in the six months from Oct 2003 to Mar 2004. Of these, 20,557 received quinine prescriptions in retail pharmacies, 8,369 at MTF pharmacies (does not add to 28,655 because some beneficiaries used both points of services).
- Utilization of quinine is increasing, most likely due to the increased numbers of patients 65 years of age and older using the retail network.

The Committee agreed that the non-availability of quinine in the TMOP probably did not decrease the use of quinine for nocturnal leg cramps, since patients could readily fill these prescriptions at retail network pharmacies. The Committee voted to add quinine to the TMOP Formulary. Quinine will be available from the TMOP and retail network without a prior authorization or other formulary restriction. Considerations included:

- Clinical evidence of efficacy of quinine in the treatment of nocturnal leg cramps and the existence of criteria, guidelines, and reviews supporting cautious use in patients for whom the benefits outweigh the considerable risks.
- The absence of an FDA-mandated special distribution process or special monitoring requirements for quinine.
- The incongruence of denying prescriptions for quinine in the TMOP while filling prescriptions for quinine in retail pharmacies.

The Committee noted that the TMOP provides a patient information insert with all medications, including quinine. Patients using the TMOP have access to a toll-free number for pharmacist consultation. Individual providers and pharmacists should assess the patient-specific benefits and risks of this medication and educate patients accordingly.

12. QUANTITY LIMITS

A. *Follitropin beta (Follistim AQ)* – All injectable gonadotropins, including follitropin, currently have a quantity limit of 3600 IU per 30 days (no refills) in both TMOP and the retail network. These products are also subject to prior authorization. Follistim AQ is a new formulation of follitropin beta in a pre-filled, pre-mixed cartridge for use with the "Follistim Pen." It is supplied in a box containing 4 needles and 1 prefilled cartridge containing either 300 or 600 IU of follitropin beta. The Committee established quantity limits for this new formulation consistent with existing products. These quantity limits apply to both TMOP and retail:

   - 300 IU cartridge: 12 cartridges (3600 IU) per 30 days, no refills
   - 600 IU cartridge: 6 cartridges (3600 IU) per 30 days, no refills

B. *Anakinra (Kineret)*- As of 23 Feb 2004, Amgen stopped selling 7-syringe packs of anakinra. Anakinra is now available only as 28-syringe packs (4 weeks supply). The current quantity limit for anakinra in the TMOP is a 6-week supply (6 packages of 7 syringes). The Committee voted to change the quantity limits for anakinra to the following:

   - TMOP: 56 syringes = 2 packages of 28 syringes per 56 days (8 weeks supply);
   - Retail: 28 syringes = 1 package of 28 syringes per 28 days (4 weeks supply)

   The Committee decided to assess the impact of the increased quantity limit on utilization of anakinra before considering any changes to the current 6-week quantity limits for etanercept (Enbrel) and adalimumab (Humira), which are similar injectable agents also used for the treatment of rheumatoid arthritis and available from the TMOP.

13. PRIOR AUTHORIZATIONS (PAS)

A. *Implementation of the Growth Hormone PA* – The Committee recommended implementation of the PA in both TMOP and the retail network as of 1 Jun 2004 for new patients only (i.e., patients presenting a new growth hormone prescription at a retail

network pharmacy or the TMOP for whom there was no prescription fill for growth hormone in the preceding 180 days).

The Committee recommended that patients who are currently receiving growth hormone in the TMOP and retail network (based on use within the last 180 days) should be required to fulfill PA requirements within 180 days after being notified about the existence of the PA. A method to notify patients who are currently receiving growth hormone from the TMOP or a retail network pharmacy has not been finalized.

A total of 1147 DoD beneficiaries received at least one prescription for growth hormone during the six-month period from Oct 2003 to Mar 2004. Of these, 220 received growth hormone prescriptions in retail pharmacies, 443 at MTF pharmacies, and 506 in the TMOP (does not add to 1147 because some beneficiaries used more than one point of service).

14. ADJOURNMENT – The meeting adjourned at 1130 hours. The next meeting is scheduled for 29 and 30 June at the PEC. All agenda items should be submitted to the co-chairs no later than 4 June 2004.

APPENDIX A: DOD P&T COMMITTEE FORMULARY DECISIONS REGARDING NEWLY APPROVED DRUGS

Generic name (Trade name; manufacturer)	**FDA approval date, drug class, FDA-approved indication**	**TMOP Formulary status**	**TMOP and/or retail network formulary restrictions**	**BCF status**
Amlodipine besylate / atorvastatin tablets (Caduet; Pfizer)	2 Feb 2004. Combination tablet approved for patients for whom treatment with both amlodipine and atorvastatin is appropriate; i.e., hyperlipidemia AND hypertension, chronic stable angina, or vasospastic angina Launch date is 27 Apr 2004.	Not added to the TMOP Formulary Atorvastatin is not on the TMOP Formulary due to provisions of the statin contract; amlodipine is available from the TMOP	**Quantity Limits** General rule applies **Prior Authorization** None	Not added to the BCF **Similar BCF agents:** Nifedipine sustained release, simvastatin (contract statin)
Epinastine HCl 0.05% ophthalmic solution (Elestat; Allergan)	12 Oct 2003 (not launched until Jan 2004). Topically active antihistamine with mast cell stabilizing properties, indicated for the prevention of itching associated with allergic conjunctivitis.	Added to the TMOP Formulary	**Quantity Limits** General rule applies **Prior Authorization** None	Not added to the BCF **Similar BCF agents:** There are no ophthalmic antihistamine products on the BCF.
Tiotropium bromide inhalation powder (Spiriva HandiHaler; Boehringer / Pfizer)	30 Apr 2004 (Launch date is not expected until 11 Jun 2004). Tiotropium bromide is an anticholinergic with specificity for muscarinic receptors. It is indicated for the long-term, once daily, maintenance treatment of bronchospasm associated with chronic obstructive pulmonary disease (COPD), including chronic bronchitis and emphysema. It is not indicated to relieve dyspnea associated with COPD. The product consists of a capsule containing a dry powder formulation of tiotropium bromide, intended for use with the HandiHaler oral inhalation device.	Added to the TMOP Formulary	**Quantity Limits** TMOP: 90 caps per 90 days (3 packages of 30 caps for inhalation) Retail: 30 caps per 30 days (1 package of 30 caps for inhalation) **Prior Authorization** None	Not added to the BCF **Similar BCF agents**: Albuterol MDI; Ipratropium MDI (Atrovent); albuterol /ipratropium MDI (Combivent); salmeterol / fluticasone (Advair Diskus) and salmeterol DPI (Serevent Diskus)
Mycophenolic acid delayed-release tablets (Myfortic; Novartis)	Immunosuppressant approved for the prophylaxis of organ rejection in patients receiving renal transplants. It is administered in combination with cyclosporine and corticosteroids. This product is a new formulation of mycophenolate mofetil (Cellcept).	Added to the TMOP Formulary as a line extension	**Quantity Limits** General rule applies **Prior Authorization** None	Not added to the BCF **Similar BCF agents:** none
Clozapine orally disintegrating tablets (Fazaclo; Alamo Pharmaceuticals)	Clozapine is an atypical antipsychotic agent approved for schizophrenia. This product is formulated as an orally disintegrating tablet.	Not added to the TMOP Formulary. Clozapine is excluded from the TMOP due to monitoring requirements and dispensing restrictions mandated by the FDA.	**Quantity Limits** General rule applies **Prior Authorization** None	Not added to the BCF **Similar BCF agents**: Quetiapine (Seroquel) and risperidone (Risperidal)

APPENDIX B: COMBINED SUMMARY OF FORMULARY CHANGES FROM THE APRIL 2004 DOD P&T EXECUTIVE COUNCIL & DOD P&T COMMITTEE MEETINGS

1. **BCF CHANGES**
   A. *Additions to the BCF - None*
   B. *Deletions, changes, clarifications or exclusions from the BCF*
      1) Fexofenadine (Allegra) was removed from the BCF. There is no longer a second generation antihistamine on the BCF. The BCF now states that MTFs must have at least one second generation antihistamine on their formularies. The Council strongly encourages all MTFs to include loratadine on their formularies.
2. **TMOP FORMULARY CHANGES**
   A. *Additions to the TMOP Formulary*
      1) Epinastine HCl 0.05% ophthalmic solution (Elestat; Allergan)
      2) Tiotropium bromide inhalation powder (Spiriva HandiHaler; Boehringer/Pfizer) – has quantity limits (see Section 3 below)
      3) Mycophenolic acid delayed-release tablets (Myfortic; Novartis)
      4) Quinine
   B. *Exclusions from the TMOP Formulary*
      1) Amlodipine/atorvastatin (Caduet; Pfizer) (combination tablets) – excluded from the TMOP Formulary due to current statin contract
      2) Clozapine orally disintegrating tablets (Fazaclo; Alamo Pharmaceuticals) – excluded from the TMOP Formulary due to monitoring requirements and dispensing restrictions mandated by the FDA
      3) Sermorelin (Geref, Serono) – removed from the TMOP Covered Injectables list
3. **QUANTITY LIMIT CHANGES (RETAIL NETWORK AND TMOP)**
   A. Quantity limits for follitropin beta injection (Follistim AQ) for both TMOP and retail:
      - 300 IU cartridge: 12 cartridges (3600 IU) per 30 days, no refills
      - 600 IU cartridge: 6 cartridges (3600 IU) per 30 days, no refills
   B. TMOP quantity limits for Anakinra (Kineret) were changed to an 8-week rather than a 6-week supply, to accommodate discontinuation of the 7-syringe pack. Anakinra is now available in 28-syringe packs only. Quantity limits in the retail network remain unchanged.
      - TMOP: 56 syringes = 2 packages of 28 syringes per 56 days (8 weeks supply);
      - Retail: 28 syringes = 1 package of 28 syringes per 28 days (4 weeks supply)
   C. Quantity limits for tiotropium bromide inhalation powder (Spiriva)
      - TMOP: 90 caps per 90 days (3 packages of 30 caps for inhalation)
      - Retail: 30 caps per 30 days (1 package of 30 caps for inhalation)
4. **CHANGES TO THE TMOP PRIOR AUTHORIZATION (PA) PROGRAM**
   A. *Growth Hormone* – The Committee recommended implementation of the PA in both TMOP and the retail network as of 1 Jun 2004 for new patients only (i.e., patients presenting a new growth hormone prescription at a retail network pharmacy or the TMOP for whom there was no prescription fill for growth hormone in the preceding 180 days). A method to notify patients who are currently receiving growth hormone from the TMOP or a retail network pharmacy about the existence of the PA has not been finalized.

Corrections - Page 7 amended to correct prices for formoterol and salmeterol, following initial dissemination of these minutes on 13 May 2004

The next meetings of the DoD P&T Committee have been changed to Tuesday 13 July and Wednesday 14 July, 2004.

Department of Defense Pharmacoeconomic Center

2421 Dickman Rd., Bldg. 1001, Rm. 310
Fort Sam Houston, TX 78234-5081

MCCS-GPE **20 April 2004**

MEMORANDUM FOR: Executive Director, TRICARE Management Activity (TMA)

SUBJECT: Minutes of the Department of Defense (DoD) Pharmacy and Therapeutics (P&T) Executive Council Meeting

1. The DoD P&T Executive Council convened at 1300 hours on 20 April 2004 at the DoD Pharmacoeconomic Center, Fort Sam Houston, Texas.

2. VOTING MEMBERS PRESENT

COL Daniel D. Remund, MS	DoD P& T Committee Co-chair
CDR Terrance Egland, MC (Via VTC)	DoD P& T Committee Co-chair
COL Joel Schmidt, MC	Army
COL Doreen Lounsbery, MC	Army

Elizabeth Hearin	DoD Pharmacoeconomic Center
Elaine Furmaga	Department of Veterans Affairs
Four pharmacists	Iraq Ministry of Health

3. REVIEW MINUTES OF LAST MEETING

The minutes from the last meeting were accepted as written.

4. INTERIM DECISIONS/ADMINISTRATIVE ISSUES

None.

5. NATIONAL PHARMACEUTICAL CONTRACTS AND BLANKET PURCHASE AGREEMENT (BPA) AWARDS, RENEWALS AND TERMINATIONS

A. *New Contracts Awarded* – tramadol (Caraco) and ranitidine (Golden State Medical). The Council encourages MTF pharmacies to order these products from the contracted companies.

B. *Changes to Existing Contracts*

1) The next option year was exercised for contracts on the following drugs: 35 mcg ethinyl estradiol/1 mg ethynodiol diacetate (Pharmacia/Pfizer), zolmitriptan (AstraZeneca), etodolac (Taro), hydrochlorothiazide (Ivax), and glyburide (Pharmacia/Pfizer).

2) Additional NDCs were added to existing contracts for metoprolol 50 mg (Caraco), NDC# 57664-0477-08, and tramadol 50 mg (Caraco), NDC# 57664-0377-13.

3) Contracts for insulin syringes (BD), isosorbide mononitrate (Schwarz), and capsaicin cream (Qualitest) were extended.

4) The contracts for levobunolol, timolol, prazosin, verapamil and nortriptyline have no more options years left. They will be reevaluated for resolicitation.

C. *Contracts Pending Award* – amantadine, enalapril, salsalate, and insulin

D. More information about DoD and DoD/VA national pharmaceutical contracts may be found on the Defense Supply Center Philadelphia (DSCP) DMM-Online website at http://dmmonline.dscp.dla.mil/pharm/contractlist.asp. Contract guidance for the oral fluoroquinolones, statins, leutinizing hormone releasing hormone (LHRH) agonists, and triptans are available on the PEC website at www.pec.ha.osd.mil/national_contracts.htm.

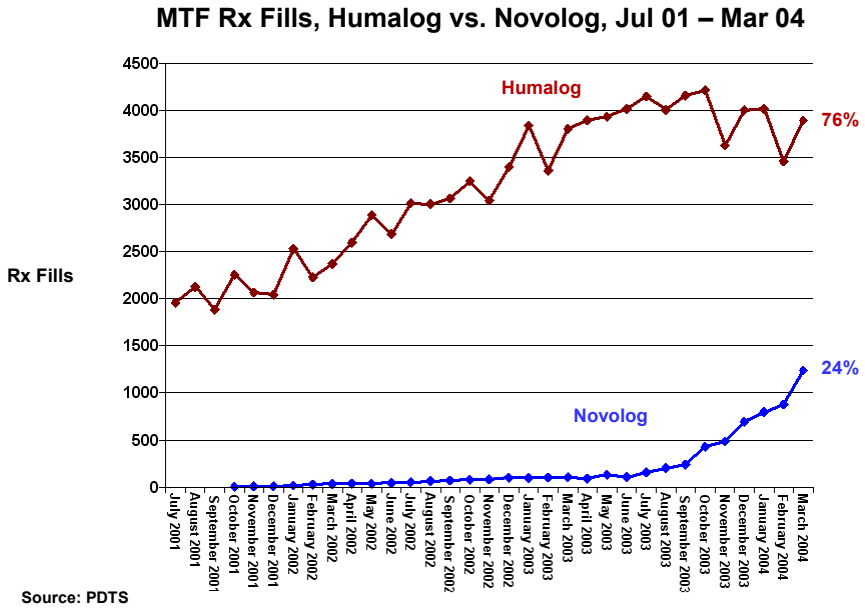
E. The Council reviewed the top 40 drug classes by MTF expenditure for FY 2003. National pharmaceutical contracts or incentive price agreements exist for medications in many of these drug classes. The remaining classes are likely targets for procurement initiatives in the future.

MTF Expenditures by Drug Class,* FY 2003**

Rank	Drug Class	$		Rank	Drug Class	$
1	Antihistamines †	$88 M		21	Metformin †	$22 M
2	NSAIDs †	$86 M		22	Leukotriene antagonists	$21 M
3	Lipotropics †	$83 M		23	Glucocorticoids	$20 M
4	SSRIs †	$64 M		24	Macrolides	$19 M
5	PPIs & H2 blockers †	$61 M		25	Antifungals	$19 M
6	Bisphosphonates †	$45 M		26	Antimalarials	$18 M
7	Calcium channel blockers†	$45 M		27	Hematinics †	$17 M
8	ACE inhibitors †	$43 M		28	Antimigraine agents †	$17 M
9	Vaccines (Hep A & B) †	$38 M		29	Beta-adrenergics (e.g., albuterol) †	$16 M
10	Anticonvulsants †	$37 M		30	Estrogenic agents †	$15 M
11	Salmeterol / fluticasone (Advair)	$31 M		31	Antipsychotics †	$15 M
12	Thiazolidinediones†	$30 M		32	Vaccines/Toxoids	$14 M
13	Quinolones †	$28 M		33	Vaccines, Gram (-) Bacilli	$13 M
14	Antiplatelet agents †	$27 M		34	Bupropion †	$13 M
15	Penicillins	$24 M		35	Miotics / intraocular pressure agents †	$13 M
16	Blood glucose diagnostics †	$24 M		36	Beta blockers †	$12 M
17	Contraceptives †	$23 M		37	Insulins †	$11 M
18	Narcotic analgesics	$22 M		38	ADHD drugs †	$10 M
19	Aqueous nasal steroids †	$22 M		39	Serotonin-norepi reuptake inhibitors	$10 M
20	ARBs	$22 M		40	Sedative/hypnotics	$10 M
Top 20 classes = $843 M 52% of total expenditures				**Top 40 classes = $1,148 M 70% of total expenditures**		

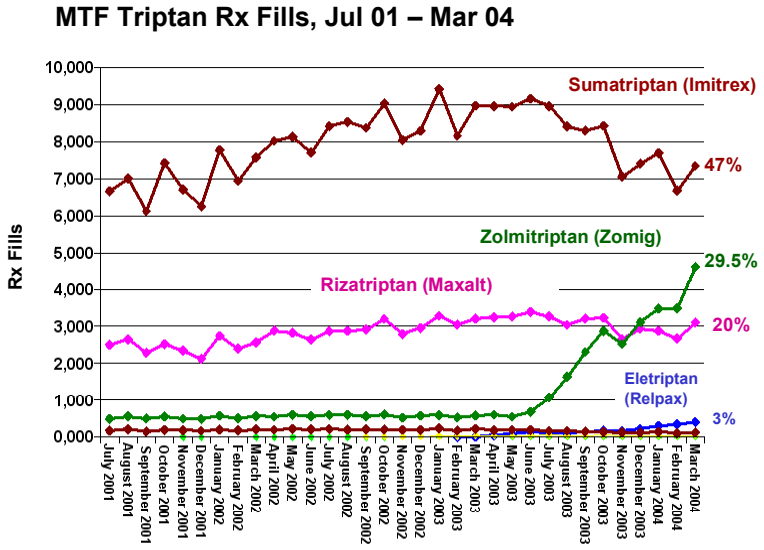
* Drug classes based on First Data Bank HIC-3 classifications
** Expenditures based on DoD Prime Vendor data. May underestimate expenditures in some drug classes, especially products not always ordered through the pharmacy prime vendor system (e.g., vaccines, blood glucose test strips)
† National pharmaceutical contracts or incentive price agreements exist.

F. The Council reviewed utilization of the rapidly-acting insulin analogue products, insulin lispro (Humalog) and insulin apart (Novolog). Due to a voluntary price reduction, Novolog costs only $17.16 per 10 mL vial while the FSS price for Humalog is $31.96 per 10 mL vial. MTFs are saving money by using Novolog rather than Humalog.



Source: PDTS

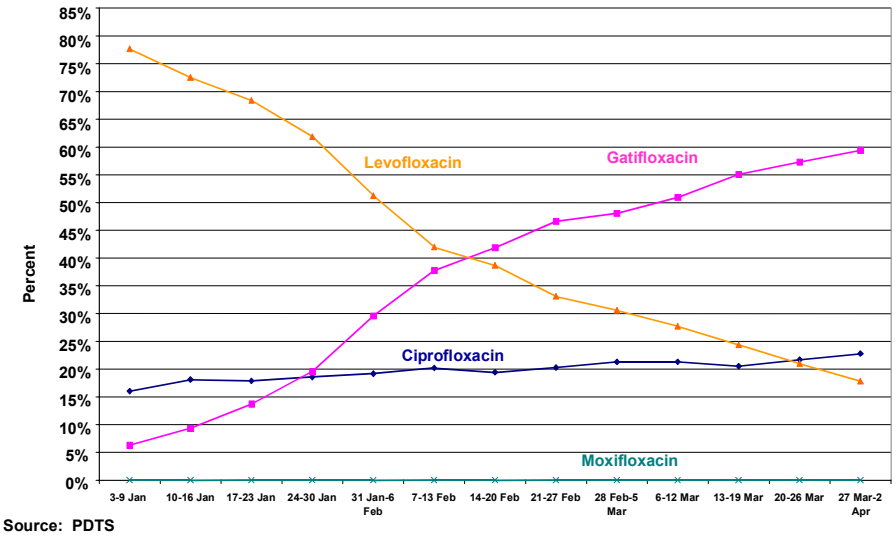
G. The Council reviewed MTF utilization of the triptans and compliance with the joint DoD/VA contract for zolmitriptan. Zolmitriptan at $3.20 per tablet (contract price) costs at least 20% less than any other triptan. Zolmitriptan should be used as the first-line triptan for all new patient starts unless there is a medical necessity to use a different triptan.



Source: PDTS

H. The Council reviewed MTF utilization of the oral fluoroquinolones and compliance with the joint DoD/VA contract for gatifloxacin. Gatifloxacin is the contract oral fluoroquinolone for the treatment of community-acquired pneumonia and sinusitis. The contract price for gatifloxacin 400 mg is $1.35 per tablet, compared to the FSS price of $5.06 per tablet for levofloxacin 500 mg. The following graph shows the weekly MTF market share for each of the oral fluoroquinolones over the last 3 months. As of the week ending 2 April 2004, almost 60% of oral fluoroquinolone prescriptions were for gatifloxacin.

MTF Oral Fluoroquinolone Rx Market Shares, Weeks Ending 8 Jan 04 – 2 Apr 04



Source: PDTS

6. BCF CHANGES AND CLARIFICATIONS

A. *Long Acting Beta Agonists*

CDR Denise Graham and CPT Jill Dacus (PEC) presented an analysis comparing the long-acting beta agonists salmeterol (Serevent Diskus), which is currently on the BCF, and formoterol (Foradil). The Council considered whether formoterol should be added to the BCF and whether salmeterol should be removed from the BCF.

Efficacy/Safety/Tolerability

Formoterol is a long acting beta-2 agonist indicated for the maintenance treatment of asthma, the prevention of bronchospasm in adults and children 5 years of age and older with reversible obstructive airways disease, acute prevention of exercise-induced bronchospasm, and maintenance treatment of bronchoconstriction in patients with Chronic Obstructive Pulmonary Disease (COPD). Clinical studies have shown comparable efficacy with formoterol compared to salmeterol in the maintenance treatment of asthma and the treatment of reversible obstructive airway disease. Safety and tolerability of the two drugs appear similar.

Formoterol has a faster onset of action than salmeterol, but this may not be a significant clinical advantage since salmeterol and formoterol are not indicated for acute bronchoconstriction. Acute bronchoconstriction should be treated with a

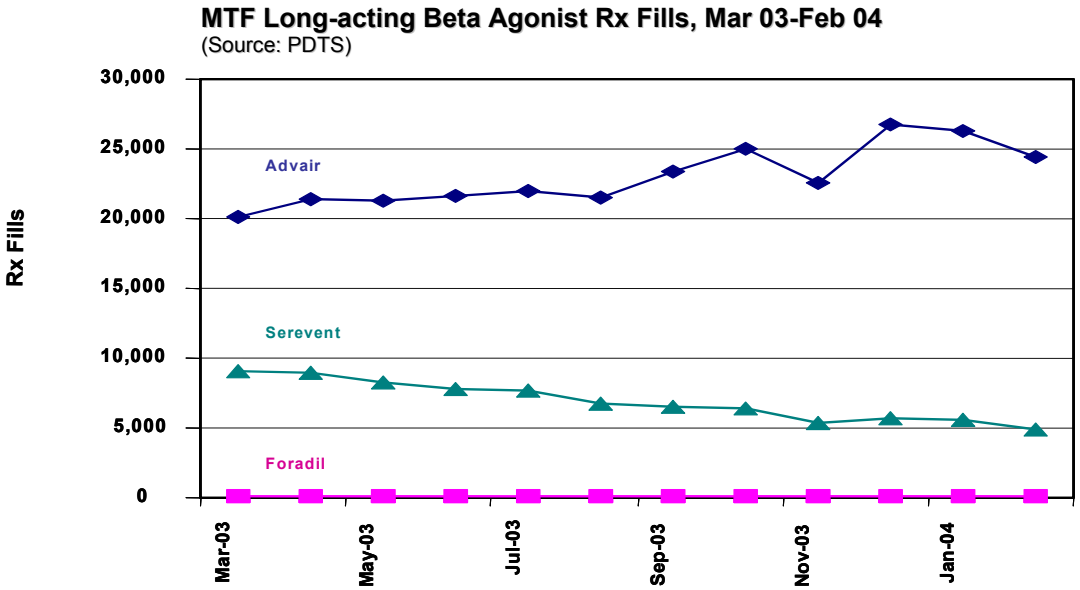
short-acting beta agonist (e.g., albuterol). Salmeterol and formoterol are typically used as adjunctive therapy with inhaled corticosteroids in patients with asthma and with ipratropium in patients with COPD.

Other Factors

- Fewer than 10% of MTFs (14/149) currently have formoterol on formulary. Salmeterol is on the BCF as a single agent (Serevent) and in combination with fluticasone (Advair).
- Patients may find the salmeterol inhaler device (Serevent Diskus) easier to use than the formoterol device (Foradil Aerolizer). Serevent Diskus is packaged as a self-contained dry powder inhaler device preloaded with 28 or 60 doses of 50 mcg of salmeterol. An indicator on top provides the number of doses remaining. Foradil Diskus is a small cylindrical device that is loaded by the patient with a capsule containing 12 mcg of formoterol and squeezed to pierce the capsule. The patient must open the device after inhaling to ensure that the entire dose was delivered. Formoterol capsules come in 12- or 60-count blister packs.
- Salmeterol may be stored at room temperature, and must be used within 6 weeks after opening the foil packet. Formoterol requires refrigeration while stored in the pharmacy, although the patient may store the product at room temperature for up to 4 months after dispensing.

Utilization

As of Feb 2004, MTFs were filling approximately 84 formoterol prescriptions per month, compared to 4,879 prescriptions per month for salmeterol. MTFs fill about 25,000 prescriptions per month for the combination salmeterol/fluticasone product (Advair).



Cost

Based on current FSS prices and recommended dosing regimens, salmeterol costs $44.57 per month compared to $32.63 per month for formoterol. The manufacturer of formoterol has offered a voluntary price reduction for formoterol to all DoD accounts at $31.50 per 60 doses regardless of BCF status. In addition they are offering a MTF based incentive agreement where MTFs can obtain a lower price in exchange for local formulary status and market share performance.

Conclusion

The Council voted unanimously not to add formoterol to the BCF. Long-acting beta agonist usage (as a single agent) is declining steadily. Formoterol may be more difficult for patients to use than salmeterol. Formoterol requires refrigeration prior to dispensing. Formoterol does not offer a significant clinical advantage over salmeterol. Although formoterol costs less than salmeterol, the Council doubted that MTFs would significantly shift usage from salmeterol to formoterol, especially in light of the overall decline in usage of long-acting beta agonists relative to the combination product (Advair). A formoterol/inhaled corticosteroid product (formoterol/budesonide) is not expected until 2006 or later.

The council voted not to remove salmeterol from the BCF in order to maintain uniform availability of a long-acting beta agonist product across MTFs.

7. ANGIOTENSIN RECEPTOR BLOCKERS (ARBS)

Bristol Myers Squibb submitted a "pre-award" GAO protest of the blanket purchase agreement (BPA) request for price quotes that the Defense Supply Center Philadelphia (DSCP) issued to pharmaceutical companies that market ARBs. Pending the resolution of this protest, the Council made no final decision regarding the addition of an ARB to the BCF.

8. SECOND-GENERATION ANTIHISTAMINES

The Claritin brand of loratadine is available through a joint DoD/VA blanket purchase agreement for $0.38 per 10-mg tablet. Generic loratadine is available at prices as low as $0.12 per 10-mg tablet and is expected to drop to as low as $0.07 per 10-mg tablet. Fexofenadine 180 mg costs $0.85 per tablet (incentive agreement price for having fexofenadine on the BCF). Fexofenadine 180 mg will likely increase to the FSS price of $1.42 per tablet if fexofenadine is removed from the BCF. The FSS price for cetirizine 10 mg is $0.96 per tablet.

At its February 2004 meeting the Council considered a proposal to remove fexofenadine from the BCF because some MTF pharmacy personnel had stated that the presence of fexofenadine on the BCF inhibits their ability to increase their use of the much less expensive loratadine. The Council voted at that time to keep fexofenadine on the BCF out of concern that MTFs may not shift enough of the market share to loratadine to offset the negative financial impact of a fexofenadine price increase. The Council did not want to remove fexofenadine from the MTF unless there was evidence that MTFs could shift more usage to loratadine.

The loratadine market share at MTFs has risen rapidly since the last meeting. Loratadine accounted for 14% of MTF prescription fills for second generation antihistamines in March 2004—nearly double the 7.5% market share that loratadine had in the first quarter of FY 2004. Loratadine accounted for over 20% of new MTF prescriptions for second generation antihistamines during the first two weeks of April 2004. An April 2004 PEC survey of 209 MTF providers indicated that 2 out of 3 would be willing to prescribe loratadine 1st line if the price was $0.10/tab or less. As of 1 May 2004, loratadine should be available from local wholesalers in bottles of 500 at $0.07/tab.

The Council reviewed several market-share and price scenarios and concluded that MTFs would likely need to achieve a loratadine market share of 25% to 32% in order to break-even financially in the second-generation antihistamine class (depending on the future prices of the second generation antihistamines and their market shares). Based on MTF performance over the last three months in shifting market-share to loratadine, the Council felt confident that MTFs will shift enough market share to loratadine to generate significant savings in this drug class. The Council voted to remove fexofenadine from the BCF, which means there is no longer a second generation antihistamine on the BCF. The BCF will now state that MTFs must have at least one second generation antihistamine on their formularies. The Council strongly encourages all MTFs to include loratadine on their formularies.

9. ADJOURNMENT

The meeting adjourned at 1730 hours. The next meeting is scheduled for 29 and 30 June at the PEC. All agenda items should be submitted to the co-chairs no later than 4 June 2004.

3. **REVIEW MINUTES OF LAST MEETING** – The minutes from the last meeting were accepted as written.

4. **INTERIM/ADMINISTRATIVE DECISIONS** – None

5. **UNIFORM FORMULARY (UF) PROPOSED RULE** – COL William Davies, DoD Pharmacy Program Director, TMA, updated the Committee on the current status of the Uniform Formulary and revisions to the DoD P&T Committee Charter. The FY 2004 National Defense Authorization Act changes the membership of the DoD P&T Committee to include only government members. The DoD P&T Committee will therefore not be subject to the provisions of the Federal Advisory Committee Act (FACA), which would have required public meetings of the DoD P&T Committee. Non-government entities will have a chance to review and comment on recommendations made by the Committee as part of the Beneficiary Advisory Panel, which will include representatives from non-government organizations and associations representing the views and interests of a large number of beneficiaries. Meetings of the Beneficiary Advisory Panel will be held in accordance with FACA.

6. BCF AND TRICARE MAIL ORDER PHARMACY (TMOP) FORMULARY ISSUES – The Committee determined the TMOP formulary status, TMOP or retail network formulary restrictions (quantity limits or prior authorization), and Basic Core Formulary (BCF) status for 8 new drugs or formulations (see Appendix A).

7. MAIL ORDER AND RETAIL NETWORK ISSUES

A. *Pegvisomant (Somavert)* –The Committee removed pegvisomant from the TMOP Covered Injectables List. Pegvisomant is subject to a controlled distribution process and it is not feasible to provide it through the TMOP.

B. *Desmopressin acetate (DDAVP) injection* – The Committee added desmopressin (DDAVP) injection to the TMOP Covered Injectables List.

C. *Use of Non-Formulary Drugs* – The Committee reviewed utilization of non-formulary drugs in the TMOP: atorvastatin (Lipitor), fluvastatin (Lescol), fluvastatin extended release (Lescol XL), lovastatin extended release (Altocor), rosuvastatin (Crestor), and esomeprazole (Nexium). Non-formulary drugs are supposed to be available from the TMOP only when the TMOP contractor validates that there is a medical necessity to use the non-formulary drug in lieu of a formulary drug. When Express-Scripts receives a prescription for a non-formulary drug, they contact the prescriber (typically by fax) and attempt to change the non-formulary drug to a formulary drug or obtain information that validates the medical necessity to use the non-formulary drug. The prescription is returned to the patient unfilled if they are unable to contact the prescriber. The Committee noted that use of esomeprazole and the lower strengths of atorvastatin were higher in the TMOP than expected. The Committee asked the PEC to work with Express-Scripts to review the criteria that are used to validate the medical necessity of using non-formulary drugs and revise the criteria if necessary.

8. PRIOR AUTHORIZATIONS (PAs)

A. *PDE-5 Inhibitors* – Health Affairs Policy 98-040, "Practice Guidelines for the Evaluation of Patients Requesting Sildenafil, (Viagra), for the Treatment of Male Impotence" applies to tadalafil (Cialis). The Committee approved changes to the PA criteria for PDE-5 inhibitors to include tadalafil (Cialis). Please see Appendix A for details.

B. *Growth Hormone* – On July 23rd 2003 the FDA approved Humatrope (somatropin [rDNA origin] for injection) as a treatment for non-growth hormone dependent short stature, also known as idiopathic short stature (ISS). Treatment of ISS is not considered medically necessary, and thus is not covered by TRICARE.

CDR Don Nichols (PEC) presented proposed PA criteria for the use of growth hormone in adults and children. The PA criteria were developed by reviewing the literature, preparing draft criteria, soliciting interactive review and comment from a group of approximately 22 pediatric and adult endocrinologists, and then fine-tuning the criteria and TMOP prior authorization form. The Committee approved the criteria outlined below for the retail and mail order (TMOP) points of service:

- Coverage provided for:
  - Growth Hormone Deficiency in children and adults as a result of pituitary disease, hypothalamic disease, surgery or radiation therapy

- Chronic renal insufficiency before renal transplantation with associated short stature
- Other known renal indications: autorecessive polycystic kidney disease, cystinosis and hypophosphatemic rickets in the pediatric population
- Short stature in patients with Turner Syndrome or Prader-Willi syndrome
- Infants born small for gestational age that have not reached age appropriate height by 24 months of age
- Human immunodeficiency virus-associated wasting in adults

- Coverage NOT provided for:
  - Idiopathic Short Stature
  - Depression, Aging or Obesity

The growth hormone PA will not be implemented until a beneficiary notification process has been finalized as part of implementation of the TRICARE Retail Pharmacy (TRRx) contract. A one-year grace period will be allowed for patients who previously received growth hormone to obtain a PA once beneficiary notification has been implemented. A copy of the growth hormone PA form is included as Appendix C, but the form will not be posted on the PEC website until the PA process is implemented. MTFs are encouraged to adopt the growth hormone PA criteria in order to increase the uniformity of the pharmacy benefit across all points of service. MTFs should be aware that under the portable prior authorization process, patients who receive growth hormone at MTFs would be automatically approved to receive growth hormone at TMOP or retail.

C. *Efalizumab Injection (Raptiva*) – Capt Jill Dacus (PEC) presented information to the Committee regarding efalizumab, a biologic agent recently approved by the FDA for the treatment of chronic moderate to severe plaque psoriasis in adults $\geq$ 18 years old. Efalizumab is an IgG1 humanized monoclonal antibody to the alpha chain of CD11a of leukocyte function associated antigen type 1 (LFA-1) that inhibits activation of T-cells, interferes with their adhesion to the endothelium, and slows T-cell migration. Efalizumab is administered via subcutaneous injection at a maintenance dose of 1 mg/kg per week; patients may self-administer efalizumab after training.

Adverse effects noted during clinical trials with efalizumab include a typical "first dose" reaction (headache, chills, fever, nausea, and myalgia within 2 days following the first two injections), rare thrombocytopenia (0.3% of patients [8/2762] experienced platelets < 52,000 mm^3), and an increase in serious infection rate compared to placebo (0.4% vs. 0.1%). There was also a slight excess of malignancies in patients receiving efalizumab (1.8 per 100 patient-years vs. 1.6 per 100 patient-years with placebo); it is not clear if this represents a true increase in risk. Less than 1% of patients discontinued treatment due to adverse effects. Of note is the observation that patients discontinuing treatment tended to have poorer results on restarting treatment.

The Committee considered the following to determine whether or not to institute a PA for efalizumab, and to establish criteria.

- Other biologic agents, including etanercept, adalimumab, and anakinra, all have prior authorization criteria.
- MTF dermatologists surveyed agreed that efalizumab's place in therapy should be second line after topicals, phototherapy and systemic therapy, and that dermatologists should recommend therapeutic intervention with efalizumab based on the extent and severity of plaque psoriasis.
- Efalizumab has a very narrow indication due to the specificity of its action, and should be used only for chronic moderate to severe plaque psoriasis.
- Since efalizumab inhibits T cells, it should be not be used in children whose immune systems may still be maturing.
- Efalizumab is an immunosuppressant and should not be used in conjunction with other immunosuppressive medications, or in patients whose immune systems are otherwise suppressed.
- Like other biologic agents, treatment with efalizumab is costly (about $10,000 per year based on FSS pricing).

The Committee placed efalizumab on the TMOP Covered Injectable List with the PA criteria listed below. The Committee did not establish special quantity limits for efalizumab; patients may obtain up to a 90-day supply at the TMOP and up to a 30-day supply at retail network pharmacies.

- Coverage provided for:
  - Adults (age ≥ 18 years) with chronic moderate to severe plaque psoriasis, defined as a minimum body surface area involvement of 10% OR a body surface area involvement of less than 10%, but in critical areas (e.g. palms, soles or face) and interfering with day-to-day activities

    AND
  - Have tried and failed traditional therapy, such as phototherapy (e.g. UVB, PUVA) or systemic therapy (e.g., methotrexate, acitretin or cyclosporine) OR are not candidates for phototherapy or systemic therapy

    AND
  - A dermatologist recommends treatment with efalizumab.
- Coverage NOT provided for:
  - Immunocompromised patients or those receiving immunosuppressive agents. These patients should not receive concurrent therapy with efalizumab because of the possibility of increased risk of infections and malignancies.
  - Children (age < 18 years)
  - Patients with psoriatic arthritis without plaque psoriasis

TMOP prior authorization form for efalizumab injection (Raptiva) is available on the PEC website at http://www.pec.ha.osd.mil/PA_Criteria_and_forms.htm.

D. *Revision of Prior Authorization Forms* - The Committee agreed that the TMOP prior authorization forms should include language whereby the prescriber certifies that all information on the form is accurate. The wording of the statement will be coordinated with TMA legal counsel and Express-Scripts. The Committee also agreed that the term "benefit" used in the PA forms should be changed to "coverage," since PA criteria do not determine what the TRICARE benefit is, but do establish criteria under which drugs are covered or not covered.

E. *Cox II Inhibitors* – The Committee voted to discontinue the TMOP PA for COX-2 inhibitors after considering the following:

- The costs of processing COX-2 inhibitor PAs in the TMOP probably exceed any cost-savings that are generated by the PA process.
  - About 88% of COX-2 inhibitor PAs are approved on first review, with an additional 2% approved upon resubmission. It costs DoD more to process the PAs than DoD saves by not filling 10% of the prescriptions submitted.
  - Given the absence of a PA for COX-2 inhibitors in the retail network, the PA process in the TMOP probably shifts some prescriptions to the retail network where the drug acquisition cost is the highest.
  - Although it is impossible to accurately estimate the cost-savings due to the sentinel effect of the PA (i.e., when the requirement to obtain prior authorization causes a provider to refrain from writing a prescription for the drug), the sentinel effect probably does not outweigh the cost of processing the PAs and the incremental cost of shifting prescriptions to the retail network.
- We should not continue the incongruity of having a PA for COX-2 inhibitors in the TMOP but not having a PA for COX-2 inhibitors in the retail network. The administrative burden of instituting a PA for COX-2 inhibitors in the retail network would further complicate the impending implementation of the TRICARE Retail Pharmacy (TRRx) contract and the Uniform Formulary. Discontinuing the COX-2 inhibitor PA in the TMOP will reduce the administrative burden.
- COX-2 inhibitors could possibly be competed for formulary position on the Uniform Formulary. DoD will likely save more money by competing COX-2 inhibitors for formulary position than attempting to institute a PA in the retail network.

The Committee emphasized that removing the PA requirement for COX-2 inhibitors in the TMOP does not mean that MTFs should discontinue their efforts to target the usage of COX-2 inhibitors toward patients who are at high risk for gastrointestinal adverse effects.

9. ADJOURNMENT – The meeting adjourned at 1230 hours. The next meeting will be held at Fort Sam Houston, TX at 0800 on Tuesday, 20 April 2004. This meeting would normally be held in May, but the meeting will be held in April in order to accommodate training of Iraqi pharmacists in formulary management procedures. All agenda items should be submitted to the co-chairs no later than 19 March 2004.

List of Appendices

APPENDIX A: DOD P&T COMMITTEE FORMULARY DECISIONS REGARDING NEWLY APPROVED DRUGS

Generic name (Trade name; manufacturer)	**FDA approval date, drug class, FDA-approved indication**	**TMOP Formulary status**	**TMOP and/or retail network formulary restrictions**	**BCF status**
Alfuzosin HCL extended release tablets (Uroxatral; Sanofi)	12 Jun 03: Indicated for the treatment of signs and symptoms of BPH. Not indicated for treating hypertension. Alfuzosin selectively blocks post-synaptic alpha1 receptors in the prostate.	Added to the TMOP Formulary	**Quantity Limits** General rule applies **Prior Authorization** None	Not added to the BCF **Similar BCF agents:** The alpha-blockers terazosin and prazosin are on the BCF (mandatory source contracts). Doxazosin and tamsulosin are not on the BCF.
Efalizumab injection (Raptiva; Genentech)	27 Oct 03. Injectable biologic monoclonal antibody. Indicated for the treatment of adult patients (18 years or older) with chronic moderate to severe plaque psoriasis who are candidates for systemic therapy or phototherapy. The 1 mg/kg dose is administered SQ weekly, but must be reconstituted from single-use 125 mg vials.	Added to the TMOP Formulary and TMOP Covered Injectables List	**Quantity Limits** General rule applies **Prior Authorization** Yes. See Paragraph 8C for criteria and further discussion	Not added to the BCF **Similar BCF agents:** There are no injectable products for psoriasis on the BCF.
Notes Regarding Efalizumab: Efalizumab is the only biologic approved for psoriasis that can be self-administered by subcutaneous injection. Another biologic product, alefacept [Amevive; Biogen] is approved for psoriasis, but it is typically administered as an IM injection in the physician office or clinic. The FSS cost of one efalizumab vial is $204, resulting in an anticipated yearly cost of $10,608.				
Eplerenone tablets (Inspra; Pfizer)	10 Oct 03: Aldosterone antagonist approved to improve survival of stable patients with left ventricular systolic dysfunction (ejection fraction <40%) and clinical evidence of congestive heart failure after an acute myocardial infarction. Eplerenone is also indicated for hypertension, and may be used alone or in combination with other anti-hypertensive agents.	Added to the TMOP Formulary	**Quantity Limits** General rule applies **Prior Authorization** None	Not added to the BCF **Similar BCF agents**: Another aldosterone antagonist, spironolactone, is on the BCF.
Estradiol / levonorgestrel transdermal system (Climara Pro; Berlex)	28 Nov 03: Combination estrogen / progestin patch applied once weekly for hormonal replacement therapy. It is indicated for treatment of moderate-to-severe vasomotor symptoms associated with menopause in women with an intact uterus. It is not indicated for osteoporosis.	Added to the TMOP Formulary	**Quantity Limits** General rule applies **Prior Authorization** None	Not added to the BCF **Similar BCF agents:** There are no combination estrogen/progestin patches on the BCF. The estrogen patch Esclim is on the BCF.

Generic name (Trade name; manufacturer)	**FDA approval date, drug class, FDA-approved indication**	**TMOP Formulary status**	**TMOP and/or retail network formulary restrictions**	**BCF status**
Lansoprazole delayed release capsule / naproxen tablets kit (Prevacid NapraPAC; TAP)	28 Nov 03: Combination package of lansoprazole with naproxen. Available in 15 mg lansoprazole with either 375 mg or 500 mg of naproxen. Indicated for risk reduction of NSAID-associated gastric ulcers in patients with a history of documented gastric ulcer who require the use of an NSAID in the treatment of osteoarthritis, rheumatoid arthritis, and ankylosing spondylitis. Supplied as a weekly blister card; packages contain 28 days of therapy.	Not added to the TMOP Formulary	**Quantity Limits** N/A **Prior Authorization** N/A	Not added to the BCF **Similar BCF agents:** The components of this co-packaged combination are on the BCF: lansoprazole capsules (BPA price), and naproxen tablets (mandatory generic sole source contract).
Notes Regarding Lansoprazole/Naproxen: Prevacid NapraPAC co-packages existing dosage forms/strengths of naproxen and lansoprazole together; it does not combine the two ingredients in a single dosage form. The product is intended to facilitate prophylaxis of NSAID-associated gastrointestinal events (e.g., GI bleeding) with a PPI. The Committee's primary concern about this product arose from its cost relative to the individual components, both of which are on the BCF. A BPA price of $0.65 per capsule is in effect for lansoprazole, while naproxen tablets cost $0.05-$0.06, depending on strength (generic sole source contract pricing). An FSS price for Prevacid NapraPAC was not yet available at the time of the meeting. While the FSS price for Prevacid NapraPAC will doubtless be much lower than the prime vendor pricing in effect at the time of the meeting ($3.67 per day), it is not yet clear if the product will cost substantially more than the current $0.75-0.77 per day for naproxen plus lansoprazole, based on BPA and contract pricing. Due to the prospect of excessive cost and the Committee's doubts about the value of the packaging, Prevacid NapraPAC was not added to the TMOP formulary. The Committee was unable to isolate any circumstance in which it would be considered clinically necessary for a patient to receive the co-packaged product rather than lansoprazole and naproxen in separate packaging.			
Memantine tablets (Namenda; Forest)	16 Oct 03: Indicated for the treatment of moderate to severe Alzheimer's Disease (AD). Memantine is a N-methyl-D-aspartate (NMDA) receptor antagonist with a chemical structure unrelated to that of other available AD agents, including the cholinesterase inhibitors.	Added to the TMOP Formulary	**Quantity Limits** General rule applies **Prior Authorization** None	Not added to the BCF **Similar BCF agents:** There are no NMDA receptor antagonists on the BCF. Donepezil (Aricept), a cholinesterase inhibitor indicated for the treatment of mild to moderate Alzheimers, was added to the BCF at the 11 February 2004 DoD P&T Executive Council Meeting
Notes Regarding Memantine: Memantine is the first product labeled for use in patients with moderate to severe Alzheimer's disease. The cholinesterase inhibitors (donepezil, galantamine, and rivastigmine) are labeled for use in patients with mild to moderate disease. Memantine has been studied both as monotherapy and in combination with cholinesterase inhibitors. Monotherapy studies showed a statistically significant slowing in cognitive and functional decline in patients with moderate to severe AD treated with memantine compared to placebo. Required caregiver time was significantly less for memantine treated patients than placebo, with a difference between groups of 45.8 hours per month. The clinical trial comparing combination therapy (donepezil plus memantine) vs. donepezil plus placebo in moderate to severe AD, showed patients on the combination therapy experienced significantly better outcomes than patients treated with donepezil and placebo on measures of cognition, activities of daily living, global outcomes, and behavior. It is unclear if combination therapy provides sufficiently improved outcomes to justify the incremental cost.			

Generic name (Trade name; manufacturer)	**FDA approval date, drug class, FDA-approved indication**	**TMOP Formulary status**	**TMOP and/or retail network formulary restrictions**	**BCF status**
Olanzapine / Fluoxetine capsules (Symbyax: Lilly)	2 Jan 03: Combination of olanzapine (atypical antipsychotic) and fluoxetine (SSRI) in the same capsule. Symbyax is indicated for the treatment of depressive episodes associated with bipolar disorder.	Added to the TMOP Formulary	**Quantity Limits** General rule applies **Prior Authorization** None	Not added to the BCF. The BCF listing for fluoxetine was clarified to exclude Symbyax. **Similar BCF agents:** The atypical antipsychotics quetiapine and risperidone are on the BCF. There are multiple SSRIs on the BCF, including fluoxetine.
Notes Regarding Olanzapine/Fluoxetine: Olanzapine / fluoxetine capsules (Symbyax) are available in 6 mg or 12 mg olanzapine in combination with either 25 or 50 mg of fluoxetine. Single ingredient tablets of olanzapine (Zyprexa) come in 2.5, 5, 7.5, 10 or 15 mg; fluoxetine capsules are available in 10, 20, or 40 mg. The FSS prices for Symbyax are consistent with those for olanzapine, on a cost / mg basis.				
Tadalafil (Cialis; Bayer/ GSK)	21 Nov 03. Approved for the treatment of erectile dysfunction.	Not added to the TMOP formulary	**Quantity Limits** *TMOP:* 18 tablets of any combination of the three oral PDE-5 inhibitors per 90 days (collective quantity limit). *Retail:* 6 tablets of any combination of the three oral PDE-5 inhibitors per 30 days (collective quantity limit). **Prior Authorization** Yes, see notes below.	Not added to the BCF **Similar BCF agents**: There are no PDE-5 Inhibitors on the BCF.

Notes Regarding Tadalafil: Tadalafil is the third phosphodiesterase-5 (PDE-5) inhibitor to reach the market. It is similar to sildenafil (Viagra) and vardenafil (Levitra) in terms of efficacy and safety; the primary differences are a longer onset of action (45 minutes vs ~ 27 minutes with sildenafil and vardenafil) and duration of action (36 hours vs 4 hours with sildenafil and vardenafil).

Concomitant use of all 3 PDE-5 inhibitors is contraindicated with nitrates due to the risk of hypotension. Labeling for the three products differs with respect to concomitant use with alpha blockers. Tadalafil is contraindicated for use with alpha blockers, with the exception of tamsulosin (Flomax) 0.4 mg. Concomitant use of vardenafil is contraindicated with alpha blockers. Sildenafil labeling does not contain a contraindication for concomitant use with alpha blockers, although a warning against concomitant use of sildenafil at doses above 25 mg within 4 hours of taking an alpha blocker is listed under precautions in the package labeling.

- **TMOP & Retail Network**: Tadalafil will have the same non-formulary status in the TMOP as sildenafil and vardenafil. The three oral PDE-5 inhibitors will be available only if prior authorization criteria are met. Tadalafil will be subject to the same prior authorization process as sildenafil and vardenafil, consistent with guidelines in the Health Affairs Sildenafil Policy. A quantity limit of 18 tablets per 90 days will apply in the TMOP. A quality limit of 6 tablets per 30 days will apply in the retail network. The quantity limit will apply collectively to all oral PDE-5 inhibitors. This means that no more than 6 tablets per 30-day supply of any combination of these medications will be dispensed in the retail network and no more than 18 tablets per 90-day supply will be dispensed in the TMOP.
- **BCF & MTF Formularies:** Guidelines listed in the Health Affairs Sildenafil Policy will also apply to vardenafil and tadalafil.

APPENDIX B: COMBINED SUMMARY OF FORMULARY CHANGES FROM THE NOVEMBER 2003 DOD P&T EXECUTIVE COUNCIL & THE DOD P&T COMMITTEE MEETINGS

1. **BCF CHANGES**
   A. *Additions to the BCF*
      1) Gatifloxacin oral (does not include the parenteral formulation)
      2) Bupropion sustained release 100- and 150-mg tablets
      3) Donepezil 5- and 10-mg tablets
   B. *Deletions, changes, clarifications or exclusions from the BCF*
      1) Levofloxacin oral was removed from the BCF
      2) The current BCF listing for prednisolone oral was clarified to specify prednisolone 15 mg/5 mL oral syrup
2. **TMOP FORMULARY CHANGES**
   A. *Additions to the TMOP Formulary*
      1) Alfuzosin tablets (Uroxatral)
      2) Efalizumab (Raptiva) injection – requires prior authorization, added to TMOP Covered Injectables List
      3) Eplerenone tablets (Inspra)
      4) Estradiol/levonorgestrel transdermal patch (ClimaraPro)
      5) Memantine (Namenda)
      6) Olanzapine/fluoxetine capsules (Symbyax)
      7) Desmopressin acetate (DDAVP) injection – added to TMOP Covered Injectables List
   B. *Exclusions from the TMOP Formulary*
      1) Lansoprazole/naproxen (co-packaged as Prevacid NapraPAC)
      2) Tadalafil (Cialis) – same non-formulary status in TMOP as sildenafil; available from the TMOP if prior authorization criteria are met. Quantity limits apply (see below).
3. **QUANTITY LIMIT CHANGES (RETAIL NETWORK AND TMOP)**
   A. Quantity limits for vardenafil tablets (Levitra) – will apply collectively to all oral PDE-5 inhibitors, including sildenafil (Viagra) and tadalafil (Cialis).
      - TMOP: 18 tablets per 90 days (any combination of oral PDE-5 inhibitors)
      - Retail: 6 tablets per 30 days (any combination of oral PDE-5 inhibitors)
4. **CHANGES TO THE TMOP PRIOR AUTHORIZATION (PA) PROGRAM**
   A. Vardenafil will be subject to the same prior authorization process as sildenafil, consistent with guidelines in the Health Affairs Sildenafil Policy.
   B. The COX-2 PA was discontinued (please see Section 8E for more information).
   C. A PA was instituted for efalizumab (Raptiva)
   D. The Committee approved PA criteria for growth hormone, however implementation was delayed due to communication issues related to the TRRx contract.

APPENDIX C: TMOP PRIOR AUTHORIZATION FORM FOR GROWTH HORMONE

Growth Hormone Prior Authorization Request Form

To be completed and signed by the prescriber. To be used only for prescriptions which are to be filled through the Department of Defense (DoD) TRICARE Mail Order Pharmacy (TMOP). Express Scripts is the TMOP contractor for DoD.

Your patient receives their prescription drug benefit from the Department of Defense (DoD). The DoD prescription drug benefit plan requires that we review certain requests for coverage with the prescribing physician. You have prescribed a medication for your patient that requires Prior Authorization before benefit coverage can be provided. Before giving the prescription to the patient, please make a copy of this form, complete the following questions and give the completed form, along with the prescription, to the patient. Please instruct the patient to send this completed form, along with the prescription, to Express Scripts for processing. If Express-Scripts already has your patient's prescription and has requested that you complete this form, the completed form may be faxed to: (877) 895-1900 (toll-free) or (602) 586-3911 (commercial). A copy of this form and explanations of the underlying clinical rationale and criteria for approval are available at http://www.pec.ha.osd.mil/PA_Criteria_and_forms.htm.

Drug for which Prior Authorization is requested: Growth Hormone _____

Step 1 **Please complete patient and physician information (Please Print)**

Patient Name:		Physician Name:	
Address:		Address:	
Member #:		Phone #:	
		Secure Fax #:	

Step 2 **Please complete the clinical assessment**

1. Is the patient a child (<18 years old)?	☐ Yes Please proceed to question 5	☐ No Please proceed to question 2
2. Is the patient an adult with lowered growth hormone levels secondary to the normal ageing process, obesity or depression?	☐ Yes Coverage not approved	☐ No Please proceed to question 3
3. Is the patient an adult with growth hormone deficiency as a result of pituitary disease, hypothalamic disease, trauma, surgery, or radiation therapy, acquired as an adult or diagnosed during childhood?	☐ Yes Coverage approved	☐ No Please proceed to question 4
4. Does the patient have Short Bowel Syndrome or Acquired Immunodeficiency Syndrome (AIDS) wasting or cachexia?	☐ Yes Coverage approved	☐ No Coverage not approved
5. Is the patient a child with non-growth hormone deficient short stature (Idiopathic Short Stature)?	☐ Yes Coverage not approved	☐ No Please proceed to question 6
6. Is the patient a child with growth hormone deficiency, Turner's Syndrome, Prader-Willi Syndrome, chronic renal insufficiency (or other known renal indications) or a child born small for gestational age whose epiphyses have not closed?	☐ Yes Please proceed to question 7	☐ No Coverage not approved
7. Has the patient been evaluated by a pediatric endocrinologist or nephrologist who recommends therapeutic intervention and will manage treatment?	☐ Yes Coverage approved	☐ No Coverage not approved

Step 3 **I certify the above is correct and accurate to the best of my knowledge**

Please sign and date:

MEMORANDUM FOR: Executive Director, TRICARE Management Activity (TMA)

SUBJECT: Minutes of the Department of Defense (DoD) Pharmacy and Therapeutics (P&T) Executive Council Meeting

1. The DoD P&T Executive Council convened at 0800 hours on 11 February 2004 at the DoD Pharmacoeconomic Center, Fort Sam Houston, Texas.

2. VOTING MEMBERS PRESENT

COL Daniel D. Remund, MS	DoD P& T Committee Co-chair
CDR Terrance Egland, MC	DoD P& T Committee Co-chair
COL Joel Schmidt, MC	Army
COL Doreen Lounsbery, MC	Army
LTC Emery Spaar, MS (For MAJ Travis Watson, MS)	Army
COL John R. Downs, MC	Air Force
Col Mark Nadeau, MC (For COL Bill Sykora, MC)	Air Force
LtCol Phil Samples, BSC	Air Force
CAPT Matt Nutaitis, MC	Navy
CDR Mark Richerson, MSC	Navy
CDR Patrick Marshall	Coast Guard
Joe Canzolino	Department of Veterans Affairs

VOTING MEMBERS ABSENT

None	

OTHERS PRESENT

COL William Davies, MS	DoD Pharmacy Program Director, TMA
CAPT Patricia Buss, MC	Deputy Chief Medical Officer Representative, TMA
Howard Altschwager	Deputy General Counsel, TMA
Paul Vasquez	Defense Supply Center Philadelphia
COL Kent Maneval, MS	Joint Readiness Clinical Advisory Board
CAPT Don Nichols, MC	DoD Pharmacoeconomic Center
CDR Denise Graham, MSC	DoD Pharmacoeconomic Center
CDR Ted Briski, MSC (via telephone)	DoD Pharmacoeconomic Center
LtCol Dave Bennett, BSC (via telephone)	DoD Pharmacoeconomic Center
LtCol Barb Roach, MC	DoD Pharmacoeconomic Center
CPT Jill Dacus, MC	DoD Pharmacoeconomic Center
SFC Agustin Serrano	DoD Pharmacoeconomic Center
Shana Trice	DoD Pharmacoeconomic Center
Dave Bretzke (via telephone)	DoD Pharmacoeconomic Center
Angela Allerman	DoD Pharmacoeconomic Center
Eugene Moore	DoD Pharmacoeconomic Center
Elizabeth Hearin	DoD Pharmacoeconomic Center
Debbie Khachikian	Department of Veterans Affairs

3. REVIEW MINUTES OF LAST MEETING

The minutes from the last meeting were accepted as written.

4. INTERIM DECISIONS/ADMINISTRATIVE ISSUES

The DoD Pharmacy and Therapeutics Executive Council held an interim meeting by email on 8 January 2004 and voted to add gatifloxacin (Tequin) to the Basic Core Formulary (BCF) and remove levofloxacin from the BCF. These BCF changes were made in response to a joint DoD/VA open class contract for gatifloxacin that became effective 15 January 2004 and in response to levofloxacin price increases. The contract designates gatifloxacin as the "workhorse" fluoroquinolone on the BCF for the indications of community acquired pneumonia and acute sinusitis at a contract price of $1.35/tablet for all oral dosage strengths. The levofloxacin 500 mg price increased from $2.01 to $5.06 on 31 January 2004. The Council concurred with the contract implementation guidance that the PEC previously issued to MTFs (www.pec.ha.osd.mil/national_contracts.htm). In light of the large price increase for levofloxacin, MTFs should remove levofloxacin from their formularies. Levofloxacin should only be used in cases of medical necessity—when gatifloxacin and other fluoroquinolones will not meet the clinical need of a patient. MTFs must rapidly decrease their use of levofloxacin in order to maximize the potential cost savings from the gatifloxacin contract.

5. NATIONAL PHARMACEUTICAL CONTRACTS AND BLANKET PURCHASE AGREEMENT (BPA) AWARDS, RENEWALS AND TERMINATIONS

A. The next option year was exercised for contracts on the following drugs: colchicine, micronized glyburide, goserelin, ibuprofen, lactulose, permethrin and verapamil.

B. The next option year was not exercised for Forest Pharmaceutical's diltiazem (Tiazac) sustained release due to availability of an AB-rated generic at $0.26 per capsule from Inwood, Forest's generic product line. The generic price became effective 15 December 2003 for the following strengths and NDCs:

Diltiazem SA 120mg Capsules	00259-3687-90	#90	$23.40
Diltiazem SA 180mg Capsules	00259-3688-90	#90	$23.40
Diltiazem SA 240mg Capsules	00259-3689-90	#90	$23.40
Diltiazem SA 300mg Capsules	00259-3690-90	#90	$23.40
Diltiazem SA 360mg Capsules	00259-3691-90	#90	$23.40

C. DSCP signed incentive agreements for Aranesp, Amgen's darbepoetin alfa, and Betaseron, Berlex's interferon beta-1b. The exact content and considerations offered in these agreements can be obtained from local Amgen or Berlex representatives or a copy can also be obtained via e-mail by directing a request to Ted.Briski@amedd.army.mil.

D. Incentive agreements are available on the DSCP website at http://dmmonline.dscp.dla.mil/pharm/incentives.asp. Incentive agreements currently apply to the products listed below. MTFs should ensure they are receiving the correct price for these products:

Alendronate (Fosamax)
Azathioprine (Imuran)
BG Strips (Precision QID, XTRA)
Celecoxib (Celebrex)
Cyclosporine (Gengraf)
Darbpoetin (Aranesp)
Dorzolamide/Timolol (Cosopt)
Estradiol (Esclim)
Estropipate (Ortho Est)
Erythropoetin (Procrit)
Fexofenadine (Allegra)
Fluticasone (Flonase)
Hepatitis A Vaccine (Havrix, Vaqta)
Hepatitis A & B Vaccine (Twinrix)
Hepatitis B Vaccine (Recombivax HB, Engerix-B)
Interferon Beta (Betaseron)
Isometheptene/APAP/Dichloralphenazone (Midrin)
Lansoprazole (Prevacid)
Latanaprost (Xalatan)
Leuprolide (Lupron)
Loratadine (Claritin)
Methylphenidate (Concerta)
Methylphenidate (Metadate CD)
Nisoldipine (Sular)
Olanzapine (Zyprexa)
Pimecrolimus (Elidel)
Phenytoin (Bertek, Mylan generic)
Quetiapine (Seroquel)
Risedronate (Actonel)
Risperidone (Risperdal)
Rizatriptan (Maxalt)
Rofecoxib (Vioxx)
Rosiglitazone (Avandia)
Tolterodine (Detrol, Detrol LA)
Travoprost (Travatan)
Valdecoxib (Bextra)
Warfarin (Coumadin)

6. BCF CHANGES AND CLARIFICATIONS

A. *Bupropion SR* – CPT Jill Dacus (PEC) presented an analysis regarding the proposed addition of bupropion sustained release (SR) to the BCF, which was suggested by the Council at the November 2003 meeting while discussing the new once-daily formulation of bupropion (Wellbutrin XL). The FDA recently approved generic equivalents to GSK's Wellbutrin SR 100 mg; generics for the 150 mg strength are expected to follow in the near future.

Efficacy/Safety/Tolerability – Bupropion SR is a dopamine-reuptake blocker indicated for the treatment of depression and, as Zyban, for smoking cessation. The comparative efficacy of bupropion SR compared to other antidepressants on the BCF is unknown. Bupropion is useful for the treatment of depression in patients who have unacceptable adverse effects, such as sexual dysfunction or weight gain, with the selective serotonin reuptake inhibitors (SSRIs) or tricyclic antidepressants (TCAs). It is not considered a first line antidepressant due to an increased incidence of seizures (about 0.1% at 100-300 mg/day, increasing to 0.4% at the maximum recommended dose of 400 mg/day). There is no evidence that the once-daily formulation of bupropion (Wellbutrin XL) differs from twice-daily bupropion SR with regard to safety or efficacy; the FDA approved both formulations based on bioequivalency studies vs. the immediate release (3 times daily) formulation.

Other Factors – Bupropion SR 100 mg and 150 mg are on 80% (143/179) and 90% (161/179) of MTF formularies, respectively, with the less-widely used 200-mg strength on only 25% of MTF formularies. As of Dec 2003, MTF prescriptions for bupropion SR totaled about 18,000 per month (14,000 for Wellbutrin SR and 4,000 for Zyban). It is unknown how many Wellbutrin SR prescriptions were prescribed for smoking cessation rather than depression. There are about 100,000 MTF prescriptions for SSRIs (the most commonly prescribed antidepressant class) each month.

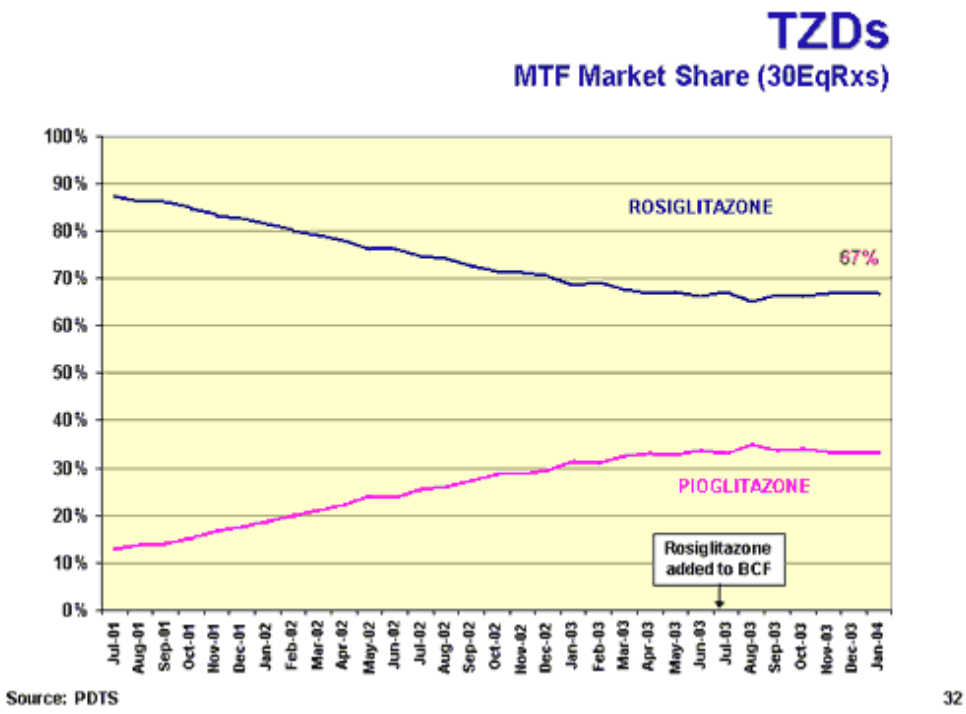
Cost – The current monthly cost for Wellbutrin SR is slightly higher than the newly introduced Wellbutrin XL ($60 vs. $58 per month, based on a typical daily dose of 300 mg). However, prices for bupropion SR should fall as generic competition increases.

The council voted unanimously to add bupropion SR 100 mg and 150 mg to the BCF based on its clinical utility in treating depressed patients who experience unacceptable adverse effects on SSRIs or TCAs, its broad representation on MTF formularies, and the increasing availability of generics. The BCF listing excludes Zyban. The presence of bupropion SR 100 mg and 150 mg on the BCF does not affect the ability of MTFs to place restrictions on the use of bupropion SR for smoking cessation if they so desire. For example, MTFs may institute and/or continue requirements that patients participate in counseling programs when bupropion SR is used for smoking cessation.

B. *Prednisolone Oral* – The BCF listing for prednisolone oral does not specify which dosage forms or strengths are on the BCF. MTF prescription data show minimal usage of prednisolone tablets. The most commonly utilized dosage form and strength is the 15 mg/5 mL syrup. The Council clarified the BCF listing for prednisolone oral to specify prednisolone 15 mg/5 mL syrup.

7. Thiazolidinediones (TZDs)

In June 2003, DoD and VA entered into an incentive agreement with GlaxoSmithKline to place rosiglitazone (Avandia), on the BCF as DoD's preferred thiazolidinedione (TZD) in exchange for a significant discount. The agreement requires that rosiglitazone maintain at least a 65% market share for DoD to achieve a substantial discount. Rosiglitazone's MTF market share had decreased from almost 90% in July 2001 to 67% in June 2003. Since the incentive agreement was implemented, rosiglitazone's market share has stabilized at 67%.



8. TRIPTANS

The zolmitriptan contract stipulates that zolmitriptan must be used for new patient starts on oral triptan therapy unless there is a medical necessity to use a different triptan. MTFs are permitted to have a second triptan on their local formulary for use by patients who have failed zolmitriptan. The contract does not mandate that patients who are already using other triptans be switched to zolmitriptan.

An analysis of prescription data for all MTFs in aggregate for December 2003 revealed that zolmitriptan was used for only 31% of new patient starts. The percentage of new patient starts for zolmitriptan varied significantly across MTFs, ranging from almost no use to as high as 81% (166/205) at Ft Bragg and 100% (22/22) at Pope AFB.

MTFs could achieve substantial cost avoidance by increasing the use of zolmitriptan for new patient starts. Zolmitriptan costs only $3.20 per dose regardless of strength. The price of other triptans depends on the formulary status at the individual MTF and any incentive agreements that may apply. However, prime vendor data for the first quarter of FY 04 show that the average cost per tablet for triptans other than zolmitriptan was $5.00. (Note: This

does not take into account the effect of rebates that an MTF may have obtained.) On average, MTFs could save $1.80 per dose by using zolmitriptan instead of other triptans.

9. CHOLINESTERASE INHIBITORS

CDR Briski presented an analysis of incentive agreements that have been proposed for donepezil (Aricept), galantamine (Reminyl) and rivastigmine (Exelon). Although the cholinesterase inhibitors have similar efficacy, donepezil is dosed once a day versus the twice daily dosing of galantamine and rivastigmine, requires fewer dosage titration steps to therapeutic dose, and appears to be better tolerated.

Donepezil accounted for 86% of the prescriptions filled at MTFs for cholinesterase inhibitors during the first quarter of FY 04. The results of a recently released clinical trial will probably help donepezil maintain or even increase its market share. The clinical trial compared donepezil in conjunction with memantine (an *N*-methyl-D-aspartate (NMDA) receptor antagonist) against donepezil plus placebo in moderate to severe Alzheimer's Disease. Patients treated with donepezil and memantine experienced significantly better outcomes than patients treated with donepezil and placebo on measures of cognition, activities of daily living, global outcome, and behavior.

Given the current and anticipated future usage trends for cholinesterase inhibitors and the pricing offered in the proposed incentive agreements, the analysis showed that DoD would obtain the greatest economic benefit by accepting the donepezil incentive agreement. The Council voted to add donepezil to the BCF and advise DSCP to accept the proposed incentive agreement for donepezil.

10. ANGIOTENSIN RECEPTOR BLOCKERS (ARBS)

A GAO protest caused the VA National Acquisition Center to withdraw the joint DoD/VA solicitation for an ARB in December 2003. The Council reviewed updated clinical information, usage data and cost data in order to formulate a DoD procurement strategy for the ARBs. The Council concluded that significant price reductions could be obtained by selecting one or more ARBs for addition to the BCF. The Council voted to have the PEC work with the Defense Supply Center Philadelphia (DCSP) to issue a BPA request for price quote for ARBs. The Council will consider the price quotes and clinical information about the ARBs to select at least one, but no more than two ARBs for addition to the BCF.

11. SECOND GENERATION ANTIHISTAMINES

The Council reviewed MTF usage and cost data for second generation antihistamines. MTF expenditures for second generation antihistamines are approaching $100 million annually. Although generic and brand name versions of loratadine are available at much lower prices than other second generation antihistamines, loratadine accounted for only 7.6% of the prescriptions for second generation antihistamines filled at MTF pharmacies during the first quarter of FY 04. Cetirizine (Zyrtec) and fexofenadine (Allegra) accounted for 47% and 45% of the prescriptions, respectively.

The Claritin brand of loratadine is available through a joint DoD/VA blanket purchase agreement for $0.38 per 10-mg tablet. Generic loratadine is available at prices as low as $0.12 per 10-mg tablet. Fexofenadine 180 mg costs $0.85 per tablet (incentive agreement

price for having fexofenadine on the BCF). The fexofenadine 180 mg price would increase to $1.42 per tablet if fexofenadine were not on the BCF. Cetirizine 10 mg costs $0.96 per tablet (Feb 2004 FSS price).

Some MTF pharmacy personnel have stated that the presence of fexofenadine on the BCF inhibits their ability to increase the use of loratadine at their MTFs. The Council considered a proposal to remove fexofenadine from the BCF. The Council was concerned that removal of fexofenadine from the BCF would not result in a large enough shift in market share to loratadine to make up for the negative financial impact of a fexofenadine price increase. The Council voted to keep fexofenadine on the BCF until there is evidence that MTFs are able to shift more usage to loratadine. The PEC will provide information to MTFs to assist them in this endeavor. The Council encourages MTFs to maximize the use of loratadine in lieu of other second generation antihistamines.

12. ADJOURNMENT

The meeting adjourned at 1400 hours. The next meeting will be held at Fort Sam Houston, TX at 0800 on Tuesday, 20 April 2004. This meeting would normally be held in May, but the meeting will be held in April in order to accommodate training of Iraqi pharmacists in formulary management procedures. All agenda items should be submitted to the co-chairs no later than 19 March 2004.

William Hudson	Humana
Ron McDonald (via TC)	Sierra
Rance Hutchings, Pharm.D.	Uniformed Services Family Health Plans (USFHP)
LTC Gwendolyn Thompson, MS, USA	Pharmacy Practice Resident
CPT Jon Feagler, MS, USA	Pharmacy Practice Resident

3. **REVIEW MINUTES OF LAST MEETING** – The minutes from the last meeting were accepted as written.

4. **INTERIM/ADMINISTRATIVE DECISIONS** – None

5. **UNIFORM FORMULARY (UF) PROPOSED RULE**- COL William Davies, DoD Pharmacy Program Director, TMA, updated the Committee on the current status of the Uniform Formulary and the DoD P&T Committee Charter. The FY 2004 National Defense Authorization Act changes the membership of the DoD P&T Committee to include only government members. The DoD P&T Committee will therefore not be subject to the provisions of the Federal Advisory Committee Act.

6. BCF AND TRICARE MAIL ORDER PHARMACY (TMOP) FORMULARY ISSUES – The Committee determined the TMOP formulary status, TMOP or retail network formulary restrictions (quantity limits or prior authorization), and Basic Core Formulary (BCF) status for 5 new drugs or formulations (see Appendix A).

7. PRIOR AUTHORIZATIONS (PAs)

A. *Growth Hormone* – Humatrope (somatropin [rDNA origin] for injection) was recently approved by the FDA as a treatment for non-growth hormone-dependent short stature, also known as Idiopathic Short Stature (ISS). This is the first FDA approval of a growth hormone product for ISS. Information regarding the use of growth hormone in pediatric growth disorders and potential costs in the treatment of ISS were presented by the PEC. Information regarding the use of somatropin in ISS considered by the FDA's Endocrinologic & Metabolic Drugs Advisory Committee as part of its review of Humatrope may be found on the FDA website at: http://www.fda.gov/ohrms/dockets/ac/cder03.html#EndocrinologicMetabolicDrugs (click on information from the 10 June 2003 meeting). For a brief overview, FDA summary slides from this advisory committee meeting are available at: http://www.fda.gov/ohrms/dockets/ac/03/slides/3957S1_03_FDA%20Slides.ppt.

Patients who have a growth hormone deficiency experience medical problems in addition to short stature (e.g. truncal adiposity, immature physical appearance, delayed puberty and decreased bone maturation), therefore it is medically necessary to provide growth hormone therapy to patients who have a growth hormone deficiency. Patients with ISS do not experience medical problems in addition to short stature; therefore it is not medically necessary to provide growth hormone therapy to patients with ISS. Since TRICARE will only pay for therapies that are medically necessary, TRICARE will not pay for growth hormone to treat ISS. The Council directed the PEC to develop a prior authorization for the use of growth hormone in adults and children. The prior authorization criteria will allow coverage for treatment of growth hormone deficiency and will deny coverage for treatment of ISS.

8. MAIL ORDER AND RETAIL NETWORK ISSUES

A. Carisoprodol Status on the TMOP Formulary – As of 9/19/2003, carisoprodol (Soma, generics) is classified as a Schedule IV controlled substance in the State of Arizona. Since the dispensing location for the TMOP is in Arizona, carisoprodol is subject to the same TMOP requirements as other Schedule IV controlled substances (limited to a 30-day supply and a maximum of 5 refills in a 6-month period).

B. Pravigard PAC Status on the TMOP Formulary – The price for Pravigard PAC (pravastatin and aspirin packaged together) recently decreased from $1.84-$2.70 to $0.74 - $1.49. Pravigard PAC is now the same price as brand name Pravachol. The Committee voted to add Pravigard PAC to the TMOP formulary.

C. Serevent Diskus Quantity Limits – The Committee revised quantity limits for the dry powder formulation of salmeterol (Serevent Diskus), which is twice as potent as the now discontinued metered dose inhaler formulation. The maximum recommended dose for Serevent Diskus is 1 inhalation twice daily. The new quantity limits are 1 inhaler (60 unit-dose blister packs) per 30 days at retail and 3 inhalers (180 unit-dose blister packs) per 90 days in the TMOP.

D. Zolmitriptan Nasal Spray Quantity Limits – The Committee approved new quantity limits for zolmitriptan nasal spray. The product is packaged 6 unit-doses per box. One or two unit-doses may be required per headache. Given the package size and package labeling indicating that the safety of treating more than 4 headaches with zolmitriptan in a 30 day period is not established, the Committee set quantity limits for zolmitriptan nasal spray at 36 units (6 boxes) per 90 days in the TMOP and 12 units (2 boxes) per 30 days in retail.

9. ADJOURNMENT – The meeting adjourned at 1200 hours. The next meeting will be held at Fort Sam Houston, TX at 0800 on Thursday, 12 February 2004. All agenda items should be submitted to the co-chairs no later than 05 January 2004.

List of Appendices

APPENDIX A: DOD P&T COMMITTEE FORMULARY DECISIONS REGARDING NEWLY APPROVED DRUGS

Generic name (Trade name; manufacturer)	FDA approval date, drug class, FDA-approved indication	TMOP Formulary status	TMOP and/or retail network formulary restrictions	BCF status
Bupropion HCl extended release tablets (Wellbutrin XL; GSK)	09 Sep 03. Indicated for the treatment of major depressive disorder in patients 18 years and older.	Added to the TMOP Formulary	**Quantity Limits** General rule applies **Prior Authorization:** None	Not added to the BCF **Similar BCF agents:** None. Several antidepressants are on the BCF, including 4 SSRIs, 4 TCAs, venlafaxine ER, and trazodone.
Bupropion HCl extended release tablets (Wellbutrin XL) are available in 150 mg and 300 mg formulations and are dosed once daily. Bupropion sustained release tablets are dosed BID and are available in 100, 150 and 200 mg tablets for depression (Wellbutrin SR), and 150 mg tablets for smoking cessation (Zyban). Generic versions are currently available only for bupropion immediate release tablets, which are available in 75 and 100 mg tablets and dosed TID. Generic versions of bupropion SR are expected to be available in the near future. Potential disadvantages related to the introduction of the Wellbutrin XL formulation include • Medication errors due to confusion about tablet strengths and differences in maximum dosages between the sustained and extended release products; • Lack of clinical trial information for the extended release product, which was approved based on bioequivalency data; • And potential misuse for smoking cessation. The potential advantage of the once-daily product for depression is largely based on convenience. Since the two peaks associated with bupropion SR are felt to be beneficial for smoking cessation, the once daily, extended release formulation is not expected to be as effective for this purpose as a twice-daily product. The extended release product is not FDA approved for smoking cessation.				
Ciprofloxacin 0.3% / dexamethasone 0.1% otic suspension (Ciprodex; Alcon)	18 Sep 03. Indicated for pediatric patients older than 6 months with acute otitis media with tympanostomy tubes, and for acute otitis externa in patients older than 6 months of age.	Added to the TMOP Formulary	**Quantity Limits** General rule applies **Prior Authorization** None	Not added to the BCF **Similar BCF agents:** There are no otic fluoroquinolones on the BCF. Neomycin / polymyxin B/ hydrocortisone otic suspension (Cortisporin, generics) is on the BCF.
Current otic preparations for treatment of ear infections include: • Ciprodex Otic (Alcon) – 0.3% ciprofloxacin/0.1% dexamethasone sterile suspension is approved in pediatric patients down to age 6 months with middle ear infections (otitis media) and tympanostomy tubes. (FSS $3.99/mL) • Cipro HC Otic (Alcon) – 0.2% ciprofloxacin/1% hydrocortisone non-sterile solution is approved for patients down to 1 year of age for acute otitis externa only. (FSS $3.99/mL) • Floxin Otic (Daiichi) and generic equivalents – 0.3% ofloxacin without a steroid component is a sterile solution approved for use in children down to 1 year of age for otitis externa, chronic suppurative otitis media, and acute otitis media in patients with tympanostomy tubes, and specifically for perforated tympanic membranes. (FSS $3.50/mL) • Cortisporin-TC Otic (Monarch) and generics – neomycin 3.3mg/polymyxin 3mg/hydrocortisone 1% is a non-sterile suspension approved for patients down to 2 years of age for otitis externa only and is not approved for use when the tympanic membrane is perforated. (FSS $0.58/mL) Currently, the BCF only contains one otic preparation for the treatment of ear infections, neomycin/polymyxin/hydrocortisone (Cortisporin Otic, generics), which is indicated for otitis externa only. Treatment options for otitis media will be reviewed at the February meeting to consider additional agents for BCF addition.				

Generic name (Trade name; manufacturer)	FDA approval date, drug class, FDA-approved indication	TMOP Formulary status	TMOP and/or retail network formulary restrictions	BCF status
Levonorgestrel 0.15 mg / ethinyl estradiol 30 mcg tablets (Seasonale; Barr)	05 Sep 03: Prevention of pregnancy. Consists of 84 active tablets followed by 7 inert tablets (extended cycle use), reducing the number of yearly cycles from 12-13 to 4. The active ingredient/dosage strength of Seasonale is the same as Nordette, a monophasic oral contraceptive.	Added to the TMOP Formulary Note: In the Retail Network, 3 co-pays will be charged, as the product inherently contains a 90-day supply of medication.	**Quantity Limits** General rule applies. **Prior Authorization** None	Not added to the BCF **Similar BCF agents**: There are several monophasic and triphasic oral contraceptives on the BCF, including LoEstrin, Lo-Ovral, and Triphasil.
Rosuvastatin tablets (Crestor; AstraZeneca)	14 Aug 03: Indicated as 1) an adjunct to diet to reduce TC, LDL, ApoB, non-HDL and TG and to increase HDL in primary hypercholesterolemia and mixed dyslipidemias; 2) as an adjunct to diet in patients with elevated TG levels; 3) to reduce LDL, TC, and Apo B in patients with homozygous familial hypercholesterolemia.	Not added to the TMOP Formulary. Medical necessity requirement must be met. (see comments)	**Quantity Limits** General rule applies to the Retail Network. **Prior Authorization** None	Not added to the BCF. The existing statin contract precludes BCF addition of rosuvastatin. (see comments) **Similar BCF agents**: Simvastatin and pravastatin.
Due to the existing DoD high potency statin contract awarded to simvastatin, rosuvastatin is reserved for patients who have a medical necessity to use a statin other than simvastatin. Examples of medical necessity include, but are not limited to: • Insufficient reduction of LDL-cholesterol after an adequate trial of simvastatin 80 mg • Patient is on long term therapy with a CYP-3A4 inhibitor or another medication known to interact with simvastatin • Patient experiences unacceptable side effects with simvastatin				
Vardenafil tablets (Levitra; Bayer / GSK)	19 Aug 03. Approved for the treatment of erectile dysfunction defined as the consistent or recurrent inability to attain and /or maintain a penile erection sufficient for sexual performance. Other drugs in the same class include sildenafil (Viagra), and tadalafil (Cialis), which was approved by the FDA on 21 Nov 03. Tadalafil (Cialis) will be reviewed by the Committee to determine TMOP status at the February 2004 meeting.	Not added to the TMOP Formulary	**Quantity Limits** Vardenafil quantity limits will be collectively 6 tablets per month with sildenafil and other oral impotency drugs. **Prior Authorization** Vardenafil will be subject to the same PA process as sildenafil (Viagra), consistent with the Health Affairs Sildenafil Policy	Not added to the BCF **Similar BCF agents:** There are no phosphodiesterase inhibitors on the BCF.
Notes about Vardenafil: Vardenafil is the second phosphodiesterase-5 (PDE-5) inhibitor to reach the market. It is similar to sildenafil in terms of pharmacokinetics (including onset of action), efficacy and safety. Concomitant use of either drug is contraindicated with nitrates due to the risk of hypotension. Concomitant use of vardenafil is contraindicated with alpha blockers; sildenafil labeling does not contain a contraindication for concomitant use with alpha blockers, although a warning against concomitant use of sildenafil at doses above 25 mg within 4 hours of taking an alpha blocker is listed under precautions. • **TMOP & Retail Network**: Vardenafil will have the same non-formulary status in the TMOP as sildenafil does. Both drugs will be available only if prior authorization criteria are met. Vardenafil will be subject to the same prior authorization process as sildenafil, consistent with guidelines in the Health Affairs Sildenafil Policy. A quantity limit of 18 tablets per 90 days will apply in the TMOP. A quality limit of 6 tablets per 30 days will apply in the retail network. The quantity limit will apply collectively to all oral PDE-5 inhibitors. This means that no more than 6 tablets per 30-day supply of any combination of these medications will be dispensed in the retail network and no more than 18 tablets per 90-day supply will be dispensed in the TMOP. • **BCF & MTF Formularies:** Guidelines listed in the Health Affairs Sildenafil Policy will also apply to vardenafil.			

APPENDIX B: COMBINED SUMMARY OF FORMULARY CHANGES FROM THE NOVEMBER 2003 DOD P&T EXECUTIVE COUNCIL & THE DOD P&T COMMITTEE MEETINGS

1. **BCF CHANGES**

   A. *Additions to the BCF* - None

   B. Deletions, changes, clarifications or exclusions from the BCF

   1) Cyclobenzaprine – the BCF listing for cyclobenzaprine oral was clarified to exclude the 5 mg strength (high cost; only available as brand Flexeril).
   2) Zolmitriptan – the BCF listing for zolmitriptan does not include zolmitriptan nasal spray (high cost; not on contract)
   3) Lansoprazole – the BCF listing for lansoprazole was clarified to exclude the oral disintegrating tablets and delayed release suspension (high cost; capsules have FDA-approved alternative administration options for use in patients with difficulty swallowing).

2. **TMOP FORMULARY CHANGES**

   A. *Additions to the TMOP Formulary*

   1) Bupropion HCL extended release tablets (Wellbutrin XL)
   2) Ciprofloxacin 0.3%/dexamethasone 0.1% otic suspension (Ciprodex)
   3) Levonorgestrel 0.15 mg/ethinyl estradiol 30 mcg tablets (Seasonale)
   4) Pravastatin/buffered aspirin (Pravigard PAC)

   B. Exclusions from the TMOP Formulary

   1) Vardenafil tablets (Levitra) – same non-formulary status in TMOP as sildenafil; available from the TMOP if prior authorization criteria are met. Quantity limits apply (see below)
   2) Rosuvastatin tablets (Crestor) – Due to existing DoD high potency statin contract awarded to simvastatin, rosuvastatin is available through the TMOP only for patients with evidence of medical necessity.

   C. Deletions, changes, or clarifications to the TMOP Formulary

   1) Carisoprodol (Soma, generics) – classified as a Schedule IV controlled substance in Arizona, where the TMOP dispensing facility is located. Subject to the same restrictions as a federally scheduled controlled substance (limited to a 30-day supply and a maximum of 5 refills in a 6-month period).

3. **QUANTITY LIMIT CHANGES (RETAIL NETWORK AND TMOP)**

   A. Quantity limit for zolmitriptan (Zomig) nasal spray:

   - TMOP: 36 units (6 boxes) per 90 days
   - Retail: 12 units (2 boxes) per 30 days

   B. Quantity limits for salmeterol dry powder inhaler (Serevent Diskus):

   - TMOP: 3 inhalers per 90 days
   - Retail: 1 inhaler per 30 days

   C. Quantity limits for vardenafil tablets (Levitra) – will apply collectively to all oral PDE-5 inhibitors, including sildenafil (Viagra) and tadalafil (Cialis)

   - TMOP: 18 tablets per 90 days (any combination of oral PDE-5 inhibitors)
   - Retail: 6 tablets per 30 days (any combination of oral PDE-5 inhibitors)

4. **CHANGES TO THE TMOP PRIOR AUTHORIZATION PROGRAM**

   A. Vardenafil will be subject to the same prior authorization process as sildenafil, consistent with guidelines in the Health Affairs Sildenafil Policy.

SFC Agustin Serrano	DoD Pharmacoeconomic Center

3. REVIEW MINUTES OF LAST MEETING

The minutes from the last meeting were accepted as written.

4. INTERIM DECISIONS/ADMINISTRATIVE ISSUES

None

5. NATIONAL PHARMACEUTICAL CONTRACTS AND BLANKET PURCHASE AGREEMENT (BPA) AWARDS, RENEWALS AND TERMINATIONS

A. The next option years were exercised for the following contracts: human insulin, and cyclobenzaprine.

B. Option years to be exercised over the next two months include the following contracts: albuterol, colchicine, permethrin, and tretinoin cream.

C. Option years not exercised due to current lower FSS prices than the contract price: rifampin, sucralfate, and salsalate.

D. DSCP signed an incentive agreement with Merck for alendronate (Fosamax) that became effective 1 October 2003. The agreement stipulates that alendronate will be the only bisphosphonate on the BCF. The class remains open on the BCF, so MTFs may have additional bisphosphonates on their formularies. The incentive agreement contains a

confidentiality clause that prohibits disclosure of the specific terms and conditions of the agreement, but it substantially reduces the price of alendronate. Estimated cost avoidance for DoD is $690,000 for the single month of October 2003.

6. PROCUREMENT INITIATIVES

A. *Oral Fluoroquinolones* – The Oral Fluoroquinolone Solicitation was posted on October 22, 2003. The solicitation offers the addition of a single oral fluoroquinolone to the Basic Core Formulary (BCF) as a workhorse agent to use in the treatment of community acquired pneumonia (CAP) and sinusitis. The solicitation closed on November 11, 2003. The award is pending.

B. *Angiotensin Receptor Blockers (ARBs)* – The ARB Solicitation was released in August 2003. The solicitation has been protested. DoD/VA is addressing the protest.

C. *Cholinesterase Inhibitors* – Two companies have offered BPAs on cholinesterase inhibitors. The Council asked the PEC to analyze the proposed BPAs and make recommendations at the next meeting.

D. *Brimonidine 0.2% Ophthalmic Solution* – The current BCF listing for brimonidine ophthalmic solution specifies the 0.15% formulation (Alphagan P). The Council placed Alphagan P on the BCF in Feb 2002 due to the planned phase-out of the 0.2% formulation by the manufacturer. The difference between the formulations is the preservative used; the 0.15% formulation (Alphagan P) contains a purite preservative, while the 0.2% formulation contains a benzylalkonium (BAK) preservative. Generic equivalents of the 0.2% formulation are now available. As part of the FDA review of generic brimonidine, the FDA determined that differences in intra-ocular pressure (IOP) lowering and adverse events between the two formulations were not clinically significant. Since generic versions of brimonidine 0.2% cost considerably less than brimonidine 0.15% (Alphagan P), the Council expressed interest in a potential sole source contract to compete generic brimonidine products for BCF addition. This issue will be reviewed at the next meeting.

7. REVIEW OF EXISTING PROCUREMENT INITIATIVES

A. *LHRH Agonists* – Goserelin Acetate Implant (AstraZeneca) was awarded a contract, effective 17 Feb 03, as the sole LHRH agonist on the BCF and VA National Formulary (VANF) for the treatment of prostate cancer. DoD has cost avoided approximately $213,000 since the contract was implemented. Goserelin acetate implants accounted for the following percentages (based on "treatment month equivalents") of LHRH agonist products purchased by MTFs during September 2003:

- DoD: 43%
- AF: 34%
- Army: 40%
- Navy: 59%

The contract reduced the price of goserelin acetate implants by 32%, which would have yielded a potential cost avoidance of $579,564 if goserelin acetate implants had accounted for 100% of the purchases. Since this class of drugs has indications other than

prostate cancer, some utilization of competing products is expected. Goserelin's market share is increasing slightly.

B. *Statins* – Simvastatin (Merck and Co) was awarded a joint VA/DoD contract, effective 1 May 03, as the sole high-potency statin on the BCF and VANF for the treatment of hyperlipidemia. MTFs may also have lovastatin and either pravastatin or fluvastatin on their formularies. DoD cost avoided approximately $31,652,000 during FY 03 within this class of drugs. The cost avoidance includes the old DoD contract and the first 3 months of the joint VA/DoD contract. Simvastatin accounted for the following percentages (based on tablets/capsules) of statins purchased by MTFs during September 2003:
   - DoD: 93.4%
   - AF: 95.6%
   - Army: 92.8%
   - Navy: 90.7%

   On average, simvastatin prices are 20% less than they were under the initial DoD statin contract and 45% less than they were prior to the initial contract.

C. *Triptans* – Zolmitriptan (AstraZeneca) was awarded a contract, effective 11 July 03, as the sole 5HT1 agonist on the BCF. MTFs may have no more than one 5HT1 agonist in addition to zolmitriptan on their formularies. DoD cost avoided $701,843 during the first two months of the contract. Zolmitriptan accounted for the following percentages (based on tablets) of triptans purchased by MTFs during September 2003:
   - DoD: 12%
   - AF: 12%
   - Army: 13%
   - Navy: 11%

   Zomitriptan prices are 50% less than they were before the contract. Given the large price reduction, MTFs can increase their cost avoidance by maximizing the use of zolmitriptan in lieu of other 5HT1 agonists.

D. *Nasal Steroids* – An incentive agreement for fluticasone (Flonase) nasal spray became effective 1 January 2003 and stipulated that fluticasone would be the sole aqueous nasal corticosteroid on the BCF. The class remains open on the BCF, so MTFs may have additional nasal corticosteroids on their formularies. The incentive agreement did not reduce the price of fluticasone, but it prevented an increase in price that would have occurred if MTFs had to purchase the product at the Federal Supply Schedule (FSS) price. Fluticasone nasal spray accounted for 87% of the nasal corticosteroid prescription fills at MTF pharmacies in September 2003.

E. *Proton Pump Inhibitors (PPIs)* – Rabeprazole (Aciphex) and lansoprazole (Prevacid) are the two PPIs on the BCF in accordance with the terms of incentive agreements that took effect 1 April 2003. The class remains open on the BCF, so MTFs may have additional PPIs on their formularies. Rabeprazole and lansoprazole accounted for approximately 75% and 17% respectively of PPI prescription fills at MTFs in September 2003. The weighted average cost per dose for PPIs was $0.80 in September 2003, compared to $0.40 per dose for most of calendar year 2002. The increase in cost is primarily due to a large price increase for rabeprazole. Prices for PPIs may decrease when price competition increases for generic omeprazole.

F. *Thiazolidinediones (TZDs, "Glitazones")* – Rosiglitazone (Avandia) is the only TZD on the BCF in accordance with the terms of an incentive agreement that took effect in July 2003. The class remains open on the BCF, so MTFs may have additional TZDs on their formularies. Rosiglitazone accounted for 66% of the 30-day equivalent prescriptions for TZDs at MTFs in September 2003. DoD cost avoidance for the first two months of the agreement is approximately $360,000.

G. *Second-Generation Antihistamines* – Loratadine is available to MTFs through an incentive agreement at less than half the price of other second-generation antihistamines, but loratadine accounted for only 6% of 30-day equivalent prescriptions for second-generation antihistamines at MTFs as of October 2003. The weighted average cost per dose for second-generation antihistamines at MTFs increased from $0.70 in March 2003 to $0.86 in August 2003. The Council encourages MTFs to maximize the use of loratadine (consistent with patients' clinical needs) in lieu of other second-generation antihistamines.

H. *Other Blanket Purchase Agreements (BPAs)* – The Council reviewed utilization data for ophthalmic prostaglandins, atypical antipsychotics, topical immunomodulators (TIMs), and tolterodine extended release. An estimate of the cost avoidance realized will be reported at the next meeting.

8. PHOSPHODIESTERASE-5 (PDE-5) INHIBITORS FOR ERECTILE DYSFUNCTION

In light of the recent FDA approval of a second PDE-5 inhibitor—vardenafil (Levitra)—the Health Affairs Director of Clinical Program Integration asked the DoD P&T Executive Council to review Health Affairs Policy 98-040, "Practice Guidelines for the Evaluation of Patients Requesting Sildenafil, (Viagra), for the Treatment of Male Impotence" and recommend whether the policy should be continued, modified, or rescinded. The policy mandates that sildenafil will be:

- non-formulary throughout the Military Health System (MHS)
- provided to patients only through a special order or prior authorization process
- subject to a quantity limit of six tablets per month

Based on information provided by the PEC, the Council identified the following concerns with Health Affairs Policy 98-040:

- The mandatory non-formulary status and requirement to special order or prior authorize prescriptions for sildenafil are an administrative hassle for patients, prescribers and pharmacies.
- The mandatory non-formulary status and requirement to special order or prior authorize sildenafil prescriptions inhibits the ability of MTF pharmacies to "recapture" prescription workload from the more expensive retail point of service.
- The mandatory non-formulary status precludes DoD from using formulary or procurement strategies to reduce the acquisition cost of PDE-5 inhibitors.
- One of the goals of the prior authorization process in the TMOP and retail network pharmacies is to identify patients who have psychogenic versus organic erectile

dysfunction because TRICARE does not cover the treatment of psychogenic erectile dysfunction. The prior authorization process is not meeting this goal because providers typically do not attempt to differentiate psychogenic erectile dysfunction from organic erectile dysfunction or mixed psychogenic/organic erectile dysfunction. The diagnostic tests required to confirm the diagnosis of organic erectile dysfunction are generally considered to be excessively expensive, invasive and pose unnecessary risk to the patient.

- The special order or prior authorization process is probably increasing the cost of providing erectile dysfunction therapy. In the TMOP, 27% of the prior authorization requests would have to be denied in order for DoD to break even on the cost of processing the prior authorizations versus the drug costs avoided by denying prescriptions. Over 95% of PA requests are approved in the TMOP. Unless the "sentinel effect" of the prior authorization process is large, DoD is losing money on the prior authorization process. [Note: The "sentinel effect" occurs when the requirement to obtain prior authorization causes a provider to refrain from writing a prescription for the drug.]

The Council voted to recommend that Health Affairs rescind HA Policy 98-040 and allow the DoD P&T Committee to manage the use of PDE-5 inhibitors as follows:

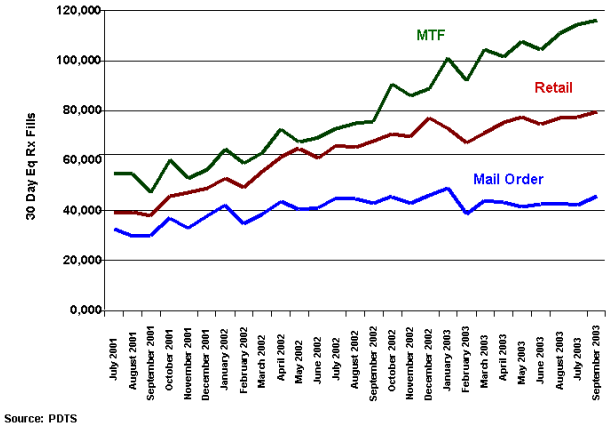
- Retain the quantity limit of six tablets per month.
- Discontinue the requirement for special order or prior authorization.
- Continue to utilize the prospective drug utilization review capabilities of CHCS and PDTS for safety monitoring.
- Consider formulary or contracting strategies to reduce the acquisition cost of PDE-5 inhibitors.

Although Health Affairs Policy 98-040 refers only to sildenafil, all PDE-5 inhibitors will be subject to the provisions of HA Policy 98-040 until Health Affairs rescinds or revises the policy.

9. DRUG/DRUG CLASS EVALUATIONS

A. Cox II Inhibitors – The Council reviewed the utilization and costs of non-steroidal anti-inflammatory drugs (NSAIDs), including the COX-2 selective NSAIDs ("COX-2 inhibitors"), in the three DoD pharmacy points of service. Utilization of COX-2 inhibitors is still increasing in MTFs and the retail network (see Figure 1 below).

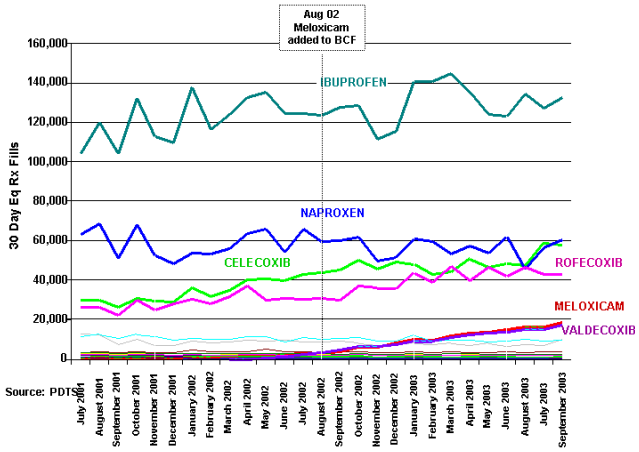
Figure 1: 30-day Equivalent Rxs for COX-2 Selective NSAIDs (Celecoxib, Rofecoxib, Valdecoxib) by Point of Service, Jul 01-Sep 03



Source: PDTS

Utilization of meloxicam (Mobic; Boehringer-Ingelheim), which was added to the BCF in August 2002 as a "relatively" COX-2 selective NSAID, has increased markedly in MTFs, closely tracking utilization of the most recently approved COX-2 inhibitor, valdecoxib (Bextra; Pfizer) (see Figure 2, below). Utilization of non-selective NSAIDs (e.g., ibuprofen, naproxen) remains essentially constant.

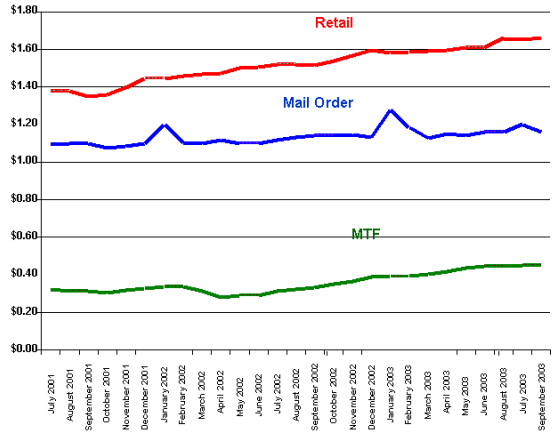
Figure 2: MTF 30-day Equivalent Rxs for NSAIDs, Jul 01 – Sep 03



Source: PDTS

As of Sep 03, monthly costs for NSAID therapy were about $8M in the retail network, $7.5M for MTFs, and $2.5 million in mail order. The cost per unit for NSAID therapy has increased in all points of service since Jul 01 (see Figure 3, below), primarily due to increasing use of COX-2 selective NSAIDs.

Figure 3: NSAID Cost per Unit by Point of Service, Jul 01 – Sep 03



Source: PDTS

Staff members from the PEC and the VA PBM are currently working on a joint DoD/VA NSAID review to support a potential joint procurement initiative for COX-2 selective and/or relatively COX-2 selective NSAIDs.

10. REQUESTS FOR BCF CHANGES

A. Cyclobenzaprine (Flexeril) 5 mg

Cyclobenzaprine tablets are on the BCF. The contract price is $0.02 per 10 mg tablet. The FDA approved a new 5 mg strength of the brand name Flexeril in February 2003. The FSS price of the branded Flexeril 5 mg tablet is $0.54. Due to the high cost of the 5 mg strength, the Council clarified the BCF listing for cyclobenzaprine to exclude Flexeril 5 mg tablets.

B. Zolmitriptan Nasal Spray

Zolmitriptan tablets are on the BCF. Zolmitriptan nasal spray was approved in October 2003. Zolmitriptan nasal spray is not included in the current triptan contract. The FSS price of zolmitriptan 5 mg nasal spray is $15.48/dose ($92.88 per box of 6 spray devices), which is much higher than the contract price of $3.20/2.5 mg or 5 mg tablet. Due to the high cost, the Council agreed that zolmitriptan nasal spray would not be included on the BCF.

C. Lansoprazole Oral Disintegrating Tablets and Delayed Release Suspension

Lansoprazole capsules (Prevacid) are currently on the BCF with an incentive agreement price of $0.65/capsule. Two new formulations of lansoprazole are available, a delayed release oral suspension and an orally disintegrating tablet. The FSS prices for the suspension are $2.00/15 mg packet and $2.28/30 mg packet. The orally disintegrating tablets are $2.80/15 mg tablet and $2.85/30 mg tablet. Although these new formulations could potentially improve ease of use in pediatric and geriatric populations, the existing

capsules are approved for pediatric use in patients 1 year of age or older. They can be opened and sprinkled on soft foods or mixed with liquids and administered enterally. The delayed release suspension comes in packets that must be mixed with water and used immediately upon reconstitution. Since the suspension thickens quickly they should not be used enterally. Due to the high cost and the existence of FDA approved alternative administration options for lansoprazole capsules, the Council clarified the BCF listing for lansoprazole to exclude the oral disintegrating tablets and delayed release suspension.

D. Transdermal Scopolamine Patch

CPT Jill Dacus (PEC) presented a request from a nurse anesthetist for the addition of transdermal scopolamine patch to the BCF. The requestor's rationale was based on two considerations:

1. Transdermal scopolamine would be more cost effective than the majority of serotonin antagonists (e.g., dolasetron, granisetron, ondansetron) for prophylaxis of post-operative nausea and vomiting (PONV).

2. The potential exists for increased use of transdermal scopolamine in ambulatory surgery patients now that droperidol, formerly the most popular antiemetic for PONV, has a black box warning for QT prolongation.

Efficacy/Safety/Tolerability – Transdermal scopolamine has been proven efficacious in the prophylaxis of PONV. In a meta-analysis of 23 trials with scopolamine (N = 979) and placebo (N = 984), the relative risk for vomiting was 0.69 (95% CI 0.58-0.82), with an absolute risk reduction of 17%, and a number needed to treat (NNT) of 5.9. However, the American Society of Anesthesia Task Force on Postanesthetic Care's 2002 Practice Guidelines do not recommend scopolamine patches as first line prophylaxis, stating that the evidence for its use is less robust than for other anti-emetic agents. Scopolamine is contraindicated in children and patients with narrow angle glaucoma. Caution is advised in the elderly due to increased sensitivity to scopolamine's CNS effects, such as confusion, agitation, and hallucinations. The most common side effect is dry mouth, which occurs in 2 out of 3 patients. Administration of scopolamine for prophylaxis of PONV following ambulatory surgery is somewhat cumbersome because the patient would have to obtain the patch and apply it the evening before surgery.

Cost – The MTF average cost per dose for scopolamine is generally lower than the cost for serotonin antagonists, but is higher than the cost for other antiemetics used for PONV (e.g. promethazine). MTFs currently spend about $250K per month on serotonin antagonists, compared to $50,000 per month or less for other perioperative antiemetics.

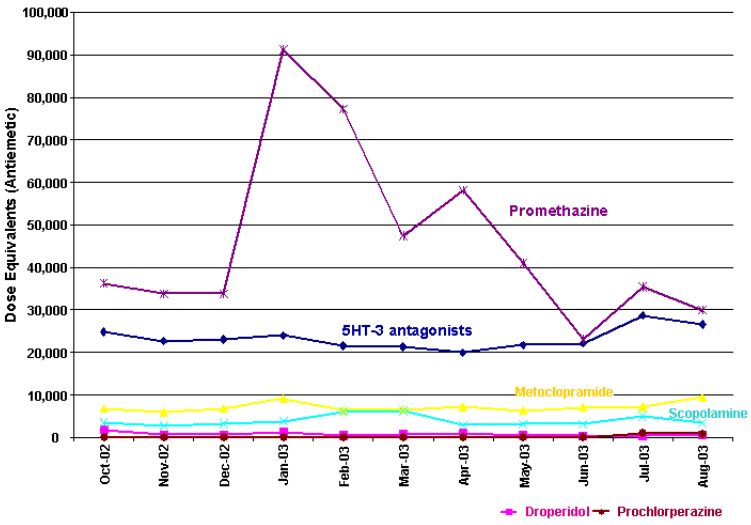
Table 1: Prime Vendor Acquisition Costs (Mean Cost per Dose, Oct 02 – Aug 03)

Antiemetic	Dosage & Route	Mean Cost per Dose
Scopolamine	1.5 mg/24 h TD placed night before surgery	$6.98*
Droperidol	1.25mg IM/IV prior to surgery	$1.63
Prochlorperazine	5-10mg IM/IV 1-2hr before surgery	$3.76-7.56
Promethazine	25-50 mg IM/IV 1-2hr before surgery	$0.05-0.16
Dolasetron	100mg PO, 12.5mg IV, within 2h start of surgery	$5.01, $24.46
Granisetron	1mg IV 30sec before anesthesia induction	$58.24
Ondansetron	16mg PO, 16mg solution PO, 4mg IV, 1hr before anesthesia	$32.46, $38.00, $11.86
Metoclopramide	10-20mg IM injection near end of surgery	$1.92-3.84

*Note: 87% of MTF purchases were for scopolamine patches in boxes of 4 at a cost of $8.59/patch; 23% of purchases were for boxes of 24 at a cost of $2.68/patch.

Utilization –MTFs purchase more dose equivalents of serotonin antagonists, promethazine and metoclopramide than they do scopolamine transdermal patches. However, purchases of scopolamine patches are higher (in terms of dose equivalents) than droperidol, which has a new black box warning, or prochlorperazine, which has not been widely available due to a national drug shortage. Table 4 shows total purchases of all of these agents, which may also be used for indications other than prophylaxis of PONV.

Figure 4: MTF Purchases of Injectable and Transdermal Antiemetics By Dose Equivalents (Oct 02 – Aug 03)



Conclusion: The Council voted unanimously not to add transdermal scopolamine to the BCF based on its high cost, low utilization, cumbersome administration requirements for PONV, and the American Society of Anesthesia Task Force on Postanesthetic Care recommendations.

E. Extended Release Morphine

Due to a lack of raw materials (opium poppy), there is a shortage of 15 mg and 30 mg strengths of MS Contin and generic morphine sulfate extended release products other than Mallincrodt's product. Mallincrodt anticipates no shortages of any strength since it is the principal supplier for all manufacturers of morphine sulfate products. The current BCF listing is for MS Contin or its generic equivalent in strengths of 15, 30, and 60 mg. Mallincrodt has an FDA-approved generic morphine sulfate extended release product that is A-B rated to MS Contin. FSS pricing for Mallinckrodt's product is less than the current FSS price for MS Contin. MTFs should be aware that the generic Mallincrodt product is currently a stable source of supply for oral morphine sulfate extended release.

11. ADJOURNMENT

The meeting adjourned at 1400 hours. The next meeting will be held at Fort Sam Houston, TX at 0800 on Wednesday, 11 February 2004. All agenda items should be submitted to the co-chairs no later than 05 January 2004.

MCCS-GPE **6 AUGUST 2003**

MEMORANDUM FOR: Executive Director, TRICARE Management Activity (TMA)

SUBJECT: Minutes of the Department of Defense (DoD) Pharmacy and Therapeutics (P&T) Committee Meeting

1. A meeting of the DoD P&T Committee convened at 0800 hours on 6 August 2003, at the TRICARE Management Activity (TMA), Falls Church, VA.

2. VOTING MEMBERS PRESENT

CDR Terrance Egland, MC	DoD P& T Committee Co-chair
COL Daniel D. Remund, MS	DoD P& T Committee Co-chair
COL Joel Schmidt, MC	Army
COL Doreen Lounsbery, MC	Army
COL Mike Heath, MS (For MAJ Travis Watson, MS)	Army
LtCol Kimberly May, MC (For Col John R. Downs, MC)	Air Force
Col Bill Sykora, MC	Air Force
LtCol Phil Samples, BSC (For LtCol George Jones, BSC)	Air Force
CAPT Matt Nutaitis, MC	Navy
CDR Mark Richerson, MSC	Navy
CAPT Charles Bruner	Coast Guard
Rance Hutchings, Pharm.D. (For Dr. Trevor Rabie)	Uniformed Services Family Health Plans (USFHP)
Francine Goodman (For Mike Valentino)	Department of Veterans Affairs

VOTING MEMBERS ABSENT

None	

OTHERS PRESENT

COL William Davies, MS	DoD Pharmacy Program Director, TMA
Col Ardis Meier, BSC	Air Force Pharmacy Consultant
CAPT Joe Torkildson, MC, USN	DoD Pharmacoeconomic Center
CDR Denise Graham, MSC, USN	DoD Pharmacoeconomic Center
CDR Ted Briski, MSC, USN	DoD Pharmacoeconomic Center
Shana Trice	DoD Pharmacoeconomic Center
LtCol Dave Bennett, USAF, BSC (Via VTC)	DoD Pharmacoeconomic Center
LtCol Barb Roach, USAF, MC (Via VTC)	DoD Pharmacoeconomic Center
CPT Jill Dacus, USA, MC (Via VTC)	DoD Pharmacoeconomic Center
David Bretzke (via VTC)	DoD Pharmacoeconomic Center
Eugene Moore (via VTC)	DoD Pharmacoeconomic Center
Angela Allerman (via VTC)	DoD Pharmacoeconomic Center
Lisa LeGette	Express Scripts
MAJ John Howe, MS	Defense Supply Center Philadelphia
Gene Lakey	TriWest
William Hudson	Humana
Kelly Lenhart	Humana

3. **REVIEW MINUTES OF LAST MEETING/ADMINISTRATIVE ISSUES** – The minutes from the last meeting were accepted as written.

4. **INTERIM DECISIONS**

An interim "email" DoD Executive Council Meeting resulted in the following BCF and TMOP changes:

- Latanoprost (Xalatan) was added to the BCF
- Rosiglitazone (Avandia) was added to the BCF
- Rosiglitazone/metformin (Avandamet) was added to the BCF
- Serevent MDI was removed from the BCF due to market withdrawal. Serevent DPI will be the remaining salmeterol on the BCF.
- Zolmitriptan oral tablets (Zomig) were added to the BCF
- Sumatriptan oral tablets (Imitrex) were removed from the BCF
- Gefitinib (Iressa) was added to the TMOP with quantity limits
- Lovastatin extended release (Altocor) was removed from the TMOP

5. **UNIFORM FORMULARY (UF) PROPOSED RULE**- COL William Davies, DoD Pharmacy Program Director, TMA, stated that the current plan is to implement the Uniform Formulary in conjunction with the TRICARE Retail Pharmacy (TRRx) contract. The TRRx contract is scheduled for implementation in Spring 2004.

6. **BCF AND TRICARE MAIL ORDER PHARMACY (TMOP) FORMULARY ISSUES** – The Committee determined the TMOP formulary status, TMOP or retail network formulary restrictions (quantity limits or prior authorization), and Basic Core Formulary (BCF) status for 11 new drugs or formulations (see Appendix A). The PEC also presented brief information on eleven additional new drugs or formulations not requiring action by the Committee (see Appendix B). The Committee agreed that no further review was required.

7. **MAIL ORDER AND RETAIL NETWORK ISSUES**

   A. *TMOP* – Lisa LeGette from Express Scripts provided a TMOP update to the Committee.

   B. *TMOP Prior Authorizations (PAs)* – Shana Trice provided an update on TMOP PAs.

   C. *Change to TMOP PA for Etanercept* - Etanercept (Enbrel) was recently approved for ankylosing spondylitis, a chronic disease involving inflammation of the sacroiliac, intervertebral, and costovertebral joints. Ankylosing spondylitis affects approximately 350,000 patients in the United States. The Committee unanimously added treatment of ankylosing spondylitis to the PA criteria for etanercept. TMOP PA criteria and forms are available on the PEC website at www.pec.ha.osd.mil/TMOP/TMOPhome.htm#2c-PA.

8. **CONTROLLED DISTRIBUTION OF PRESCRIPTION DRUGS** – Enfuvirtide (Fuzeon) is approved for use in combination with other antiretroviral agents for the treatment of HIV-1 infection in treatment-experienced patients with evidence of HIV-1 replication despite ongoing antiretroviral therapy. Roche Laboratories and Trimeris have contracted the distribution of Fuzeon to the specialty pharmacy operator Chronimed. Fuzeon is available through the TRICARE retail pharmacy benefit through the Fuzeon Progressive Distribution Program established by Chronimed and as described on their website, www.fuzeon.com.

   DoD has made arrangements with Chronimed to make Fuzeon available for MTF pharmacies to purchase and dispense to their patients. The procedure for MTF pharmacies to purchase Fuzeon with their department credit card is outlined on the DoD Fuzeon Procurement Form. The DoD Fuzeon Procurement Form is available for download at the PEC website, http://www.pec.ha.osd.mil/Controlled_Distribution_Drugs.htm, or in the File Library of RxNET, www.dodrxnet.org. Purchases through this mechanism will be billed at federal pricing. Commercial pricing applies to prescriptions filled through the TRICARE retail pharmacy benefit.

   Air Force pharmacies can obtain Fuzeon through the Air Force's High Dollar Program, which is managed out of Wright-Patterson Air Force Base. Air Force facilities wanting to use the High Dollar Program should complete the request forms provided by Wright-Patterson and not the DoD Fuzeon Procurement form described here.

   Questions about the DoD Fuzeon Procurement Form can be directed to David Bretzke or CDR Ted Briski of the DoD Pharmacoeconomic Center at (210) 295-1271.

9. ADJOURNMENT – The meeting adjourned at 1100 hours. The next meeting will be held at Fort Sam Houston, TX at 0800 on Friday, 14 November 2003. All agenda items should be submitted to the co-chairs no later than 06 October 2003.

List of Appendices

APPENDIX A: DOD P&T COMMITTEE FORMULARY DECISIONS REGARDING NEWLY APPROVED DRUGS

Generic name (Trade name; manufacturer)	FDA approval date, drug class, FDA-approved indication	TMOP Formulary status	TMOP and/or retail network formulary restrictions	BCF status
Moxifloxacin ophthalmic solution 0.5% (Vigamox; Allergan)	16 Apr 03: Fourth generation quinolone ophthalmic antibiotic indicated for treating bacterial conjunctivitis caused by susceptible strains of aerobic gram positive and aerobic gram negative organisms and Chlamydia.	Added to the TMOP Formulary	**Quantity Limits** General rule applies **Prior Authorization:** None	Not added to the BCF **Similar BCF agents:** None
Oxybutynin transdermal system (Oxytrol; Watson)	10 Mar 03: First transdermal formulation of oxybutynin for treatment of overactive bladder with symptoms of urge urinary incontinence, urgency and frequency. Applied every 3-4 days (twice weekly). The product is packaged in 1 carton containing 8 patches, a 30-day supply.	Added to the TMOP Formulary	**Quantity Limits** General rule applies **Prior Authorization** None	Not added to the BCF **Similar BCF agents:** Oxybutynin oral (immediate release tablets) and tolterodine extended release capsules are on the BCF
Influenza intranasal vaccine (FluMist; Medimmune/Wyeth)	17 Jun 03: First nasally administered live influenza virus vaccine. Approved for active immunization for the prevention of disease caused by influenza A and B viruses in healthy children ages 5-17 and healthy adults ages 18-49. FluMist is not to be administered to asthmatics, immunocompromised patients, or patients taking drugs which compromise the immune system (chemo agents, high dose steroids, etc).	Not added to the TMOP Formulary The product is not intended for self-administration and must remain frozen prior to use.	**Quantity Limits** N/A **Prior Authorization** None	Not added to the BCF **Similar BCF agents**: None
Omalizumab injection (Xolair; Genentech/Novartis)	20 Jun 03: First injectable monoclonal antibody that targets the IgE antibody. Approved for treatment of patients 12 years of age and older with moderate to severe allergy-related asthma that is inadequately controlled with inhaled steroid treatments. Eligible patients must have a positive skin test or *in vitro* reactivity to perennial allergies to confirm the diagnosis of allergy-related asthma.	Not added to the TMOP Formulary	**Quantity Limits** N/A **Prior Authorization** None	Not added to the BCF **Similar BCF agents**: None

Note about Omalizumab: Omalizumab injection will not be available from the TMOP due to the following reasons:

1) The product is not labeled or packaged for patient self-administration. No patient instruction information is enclosed in the package insert.
2) The risk of anaphylaxis and lack of clinical experience with omalizumab does not support its use outside of a controlled environment.
3) Reconstitution and administration requirements make patient preparation difficult. (Omalizumab is a lyophilized powder that takes 15-20 minutes to dissolve. Subcutaneous administration of the viscous liquid takes 5-10 seconds, and multiple injection sites may be needed due to the injection volume.)
4) Commercial distribution is limited to a specialty pharmacy network that supplies medications to physicians' offices.

Generic name (Trade name; manufacturer)	FDA approval date, drug class, FDA-approved indication	TMOP Formulary status	TMOP and/or retail network formulary restrictions	BCF status
Pravastatin/ buffered aspirin tablets (Pravigard PAC; BMS)	24 Jun 03: This product is not a single tablet formulation, but simply two tablets (pravastatin and buffered aspirin) packaged side-by-side in the same blister pack. Six dosage strengths are available (3 dosages of pravastatin, 20, 40 and 80 mg; with 2 aspirin dosages 81 mg and 325 mg). The product requires a prescription. Indications are to reduce the occurrence of cardiovascular events, including death, MI or stroke in patients who have clinical evidence of cardiovascular and/or cerebrovascular disease. Pravigard PAC is only indicated for secondary prevention of cardiovascular disease; pravastatin is indicated for both primary and secondary prevention.	Not added to the TMOP Formulary	**Quantity Limits** N/A **Prior Authorization** None	Not added to the BCF **Similar BCF agents:** Simvastatin
Notes about Pravigard PAC: • **TMOP**: Pravigard PAC was not added to the TMOP Formulary as it costs a lot more than pravastatin and aspirin that are not packaged together and provides no additional clinical benefit. (Pravigard PAC FSS prices: 20 mg + ASA: $1.84/day; 40 mg +ASA or 80 mg + ASA $2.70/day. Pravastatin FSS prices: 20 mg: $0.75/day; 40 mg: $1.30/day; 80 mg: $1.49/day. Aspirin: Less than $0.01/day.) Pravastatin is available from the TMOP, which will meet the clinical needs of patients with prescriptions for Pravigard PAC. • **BCF & MTF Formularies:** Pravigard PAC was not added to the BCF. The statin contract allows MTFs to have either pravastatin or fluvastatin on their formularies, but not both. MTFs cannot add Pravigard PAC to their local formulary if fluvastatin is on their formulary. MTFs may add Pravigard PAC to their formulary if pravastatin is on their formulary, but MTFs are advised not to add Pravigard PAC to their formulary because it costs too much			
Testosterone buccal system mucoadhesive (Striant; Columbia)	Jun 03: Buccal testosterone mucoadhesive is indicated for replacement therapy in males for conditions associated with a deficiency or absence of endogenous testosterone. Schedule III product.	Added to the TMOP, consistent with inclusion of other non-injectable testosterone products	**Quantity Limits** TMOP: 3 cartons per 90 days Note: although there is a 30-day supply limit on most controlled substances dispensed by the TMOP, other topical androgen replacement products have a 90-day supply limit in the TMOP. Retail: 1 carton per 30 days **Prior Authorization** None	Not added to the BCF. **Similar BCF agents:** None.
Note about Testosterone Buccal System Mucoadhesive: This product is supplied in a blister card of 10 buccal systems, with a total of 6 blister cards (60 buccal systems) in each carton. Anticipated retail cost for one month is $149.35 /60 systems= $4.97/day (need 2 systems/day). As of July 15, there was no FSS listing for this formulation.				

Generic name (Trade name; manufacturer)	**FDA approval date, drug class, FDA-approved indication**	**TMOP Formulary status**	**TMOP and/or retail network formulary restrictions**	**BCF status**
Conjugated estrogen / medroxyprogesterone acetate (Prempro 0.3/1.5; Wyeth)	Jun 03: Lower-dose formulation of Prempro contains 0.45 mg of estrogen, and 1.5 mg of progestin (existing Prempro doses include 0.625 / 2.5 mg, and 0.45 mg / 1.5 mg which was approved in April 2003). Approved for both menopausal vasomotor symptoms and osteoporosis.	Added to the TMOP (line extension)	**Quantity Limits** N/A **Prior Authorization** None	BCF listing for conjugated estrogens / medroxy-progesterone oral (Prempro) will include the 0.3/1.5 mg strength
Conjugated estrogen 0.45 mg (Premarin; Wyeth)	Jun 03: Lower-dose formulation of conjugated estrogens approved for both menopausal vasomotor symptoms and osteoporosis.	Added to the TMOP (line extension)	**Quantity Limits** N/A **Prior Authorization** None	BCF listing for conjugated estrogens will include the 0.45 mg strength.
Clonazepam orally disintegrating tablets (Klonopin Wafers; Solvay)	May 03: Rapidly dissolving formulation of clonazepam, available in 0.125, 0.25, 0.5, 1 and 2 mg sizes. There is no FSS price yet for the new formulation, but it is anticipated to be considerably more costly than generic clonazepam tablets, which cost approximately $0.05 per tab. The Committee agreed that the clinical benefit was unlikely to be sufficient to justify the increased cost for the rapidly dissolving formulation.	Added to the TMOP (line extension)	**Quantity Limits** N/A **Prior Authorization** None	The BCF listing for clonazepam 0.5 mg was clarified to exclude clonazepam orally disintegrating tablets.
Risperidone orally disintegrating tablets (Risperdal Redi-tabs; J&J)	May 03: Rapidly dissolving formulation of risperidone, available in 0.5, 1 and 2 mg strengths. Potential candidates may include psychiatric patients on directly observed therapy, or patients with swallowing difficulties. The cost of the orally disintegrating tablets is somewhat higher than the regular tablets, based on either FSS or BPA pricing. Risperidone is not available generically.	Added to the TMOP (line extension)	**Quantity Limits** N/A **Prior Authorization** None	The BCF listing for risperidone was clarified to exclude the orally disintegrating tablets.
Montelukast oral granules (Singulair; Merck)	May 03: New 4 mg oral granule formulation of montelukast. The new formulation is FDA-approved for treating asthma down to 12 months of age, and for treating seasonal allergic rhinitis down to 2 years of age. Previously, the youngest age for which montelukast was indicated was 2 years (4 mg chewable tablets). The oral granules should be mixed with carrots, applesauce, ice cream or rice; they are not to be mixed with liquids. Montelukast is not available generically. The Committee agreed that the new formulation provides an FDA-approved alternative in this age group and is likely to increase the ease of treatment.	Added to the TMOP (line extension)	**Quantity Limits** N/A **Prior Authorization** None	The BCF listing for montelukast oral was clarified to include the oral granules.

APPENDIX B: FORMULARY STATUS OF NEWLY APPROVED DRUGS NOT REQUIRING FORMAL REVIEW BY THE P&T COMMITTEE

Generic name (Trade name; manufacturer)	**Comments**
Omeprazole magnesium delayed release tablets, OTC (Prilosec OTC; Proctor and Gamble))	Indicated for treatment of frequent heartburn symptoms. Therapy should not be continued beyond 14 days. Available as 20.6 mg tablets in the magnesium salt form, which is equivalent to 20 mg of omeprazole. The over-the counter (OTC) product is not AB rated to Rx omeprazole. Prilosec OTC is anticipated to cost $0.80/tablet, but it will be packaged in blister cards of 14, 28, or 42 tablets, which may limit its usefulness to local MTFs considering formulary addition. Prescription omeprazole will remain on the market. Prices for the prescription products: Rx Prilosec: $2.11/cap (FSS); Rx generic omeprazole: $2.89/cap (retail). Prilosec OTC was not considered for addition to the BCF, since it is an OTC product. Currently there are two proton pump inhibitors (PPIs) on the BCF in an open class: rabeprazole and lansoprazole. Prilosec OTC was not added to the TMOP Formulary, since OTC agents are not a covered TRICARE benefit.
Desloratadine orally disintegrating tablets (Clarinex Redi Tabs; Schering)	Automatically added to the TMOP Formulary as a line extension. Not considered for the BCF because desloratadine (Clarinex) is not a BCF item.
Agalsidase beta (Fabrazyme; Genzyme)	Orphan drug for treating Fabry disease. Administered by IV infusion every 2 weeks. Not considered for the TMOP Formulary because it is not intended for self-administration. Not considered for the BCF due to the specialized nature of the medication.
Laronidase (Aldurazyme; Genzyme))	Orphan drug for treating the Hurler and Hurler-Scheile forms of mucopolysaccharidoses I. Administered by IV infusion q week. Not considered for the TMOP Formulary because it is not intended for self-administration. Not considered for the BCF due to the specialized nature of the medication.
Bortezomib (Velcade; Millennium Pharmaceuticals)	Proteasome inhibitor (new class of anti-cancer drugs). Third-line treatment for multiple myeloma. Administered by IV bolus injection twice/week for two weeks, followed by 10 days off therapy. Not considered for the TMOP Formulary because it is not intended for self-administration. Not considered for the BCF due to the specialized nature of the medication.
Tositumomab & I 131 tositumomab (Bexxar; Corixa Corp)	Monoclonal antibody in combination with radiation for non-Hodgkin's lymphoma. Administered by nuclear medicine. Not considered for the TMOP Formulary because it is not intended for self-administration. Not considered for the BCF due to the specialized nature of the medication.
Carbidopa / levodopa / entacapone (Stalevo; Novartis / Orion)	Combination of Anti-Parkinson's agents carbidopa/levodopa with entacapone (Comtan), a catechol-O-methyltransferase [COMT] inhibitor. Entacapone is always given with carbidopa/levodopa, and never administered by itself. The combination product is indicated for treating Parkinson's Disease patients who experience end-of-dose wearing off. Automatically added to the TMOP Formulary as a new combination of drugs already available. Not considered for the BCF since entacapone is not listed on the BCF.
Ondansetron orally disintegrating tablets (Zofran ODT; GSK)	Automatically added to the TMOP Formulary as a line extension. Not considered for the BCF because ondansetron is not listed on the BCF.
Olmesartan medoxomil /HCTZ tablets (Benicar HCT; Forest/Sankyo)	ARB in combination with HCTZ. Automatically added to the TMOP Formulary as a line extension. Not considered for BCF addition as ARB contracting initiative is in progress.
Atazanavir (Reyataz; BMS)	Protease inhibitor approved for use in combination with other antiretroviral agents for HIV. First once daily protease inhibitor. Automatically added to TMOP as an HIV agent. Not considered for the BCF due to the specialized nature of the medication.
Emtricitabine (Emtriva; Gilead)	NNRTI (non-nucleotide reverse transcriptase inhibitor) for HIV. Automatically added to TMOP as an HIV agent. Not considered for the BCF due to the specialized nature of the medication.

APPENDIX C: COMBINED SUMMARY OF FORMULARY CHANGES FROM THE DOD P&T EXECUTIVE COUNCIL MEETING, THE DOD P&T COMMITTEE MEETING, AND THE JULY 2003 INTERIM "E-MAIL" MEETING OF THE DOD P&T EXECUTIVE COUNCIL

1. **BCF CHANGES**

   A. *Additions to the BCF*

      1) Polymycin B Sulfate/Trimethoprim Ophthalmic Solution
      2) Erythromycin Ophthalmic Ointment
      3) Insulin Aspart (Novolog) vials

   Interim Meeting Decisions

      4) Latanoprost (Xalatan)
      5) Rosiglitazone (Avandia)
      6) Rosiglitazone/metformin (Avandamet)
      7) Zolmitriptan oral tablets (Zomig)

   B. Deletions, changes, clarifications or exclusions from the BCF

   Interim Meeting Decisions

      1) Serevent MDI – removed from the BCF due to market withdrawal. The remaining dry powder salmeterol formulation (Serevent Diskus) will be on the BCF.
      2) Sumatriptan oral tablets (Imitrex) – removed from the BCF due to award of the triptan contract.

2. **TMOP FORMULARY CHANGES**

   A. *Additions to the TMOP Formulary*

      1) Moxifloxacin ophthalmic solution 0.5% (Vigamox)
      2) Oxybutynin transdermal system (Oxytrol)
      3) Testosterone buccal system mucoadhesive (Striant) – quantity limits apply, see below

   Interim Meeting Decisions

      4) Gefitinib (Iressa) – quantity limits apply, see below

   B. Exclusions from the TMOP Formulary

      1) Pravastatin/buffered aspirin (Pravigard PAC)
      2) Influenza nasal vaccine (FluMist)

   C. Deletions, changes, or clarifications to the TMOP Formulary

   Interim Meeting Decisions

      1) Lovastatin extended release (Altocor) – Interim Meeting Decision

3. **QUANTITY LIMIT CHANGES (RETAIL NETWORK AND TMOP)**

   A. Quantity limit for testosterone buccal system mucoadhesive (Striant):

   - TMOP: day supply limit of 90 days (same exception to usual 30-day supply limit for controlled substances as other topical testosterone products); quantity limit of 3 cartons (180 systems) per 90 days
   - Retail: 1 carton (60 systems) per 30 days

   B. Quantity limits for gefitinib (Iressa):

   - TMOP: day supply limit of 45 days; quantity limit of 45 tablets per 45 days
   - Retail: day supply limit of 30 days; quantity limit of 30 tablets per 30 days

4. **CHANGES TO THE TMOP PRIOR AUTHORIZATION PROGRAM**

   A. The PA criteria for etanercept (Enbrel) were changed to reflect the recent FDA indication for ankylosing spondylitis. The revised form is available on the PEC website.

Department of Defense
Pharmacoeconomic Center

2421 Dickman Rd., Bldg. 1001, Rm. 310
Fort Sam Houston, TX 78234-5081

MCCS-GPE **5 August 2003**

MEMORANDUM FOR: Executive Director, TRICARE Management Activity (TMA)

SUBJECT: Minutes of the Department of Defense (DoD) Pharmacy and Therapeutics (P&T) Executive Council Meeting

1. The DoD P&T Executive Council convened at 0800 hours on 5 August 2003 at the TRICARE Management Activity (TMA), Falls Church, VA.

2. VOTING MEMBERS PRESENT

CDR Terrance Egland, MC	DoD P& T Committee Co-chair
COL Daniel D. Remund, MS	DoD P& T Committee Co-chair
COL Joel Schmidt, MC	Army
COL Doreen Lounsbery, MC	Army
COL Mike Heath, MS (For MAJ Travis Watson, MS)	Army
LtCol Kimberly May, MC (For COL John R. Downs, MC)	Air Force
Col Bill Sykora, MC	Air Force
LtCol Phil Samples, BSC (For LtCol George Jones, BSC)	Air Force
CAPT Matt Nutaitis, MC	Navy
CDR Mark Richerson, MSC	Navy
CAPT Chuck Bruner	Coast Guard
Francine Goodman (For Mike Valentino)	Department of Veterans Affairs

VOTING MEMBERS ABSENT

None	

OTHERS PRESENT

COL William Davies, MS	DoD Pharmacy Program Director, TMA
Howard Altschwager	Deputy General Counsel, TMA
CAPT Betsy Nolan, MSC	Navy Pharmacy Specialty Leader
Col Ardis Meier, BSC	Air Force Pharmacy Consultant
MAJ John Howe, BSC	Defense Supply Center Philadelphia
CAPT Joe Torkildson, MC	DoD Pharmacoeconomic Center
CDR Denise Graham, MSC	DoD Pharmacoeconomic Center
CDR (sel) Ted Briski, MSC	DoD Pharmacoeconomic Center
LtCol Dave Bennett, BSC (via VTC)	DoD Pharmacoeconomic Center
LtCol Barb Roach, MC (via VTC)	DoD Pharmacoeconomic Center
CPT Jill Dacus, MC (Via VTC)	DoD Pharmacoeconomic Center
Shana Trice (via VTC)	DoD Pharmacoeconomic Center
Dave Bretzke (via VTC)	DoD Pharmacoeconomic Center
Angela Allerman (via VTC)	DoD Pharmacoeconomic Center
Eugene Moore (via VTC)	DoD Pharmacoeconomic Center

3. REVIEW MINUTES OF LAST MEETING

A. The Council approved the minutes of the last meeting with a correction in Table Two Section 7A: the $7.84 average monthly cost for Estraderm was based on an incorrect dosing frequency of once a week. The correct dosing frequency is twice a week, so the correct average monthly cost for Estraderm is $15.68.

B. The Council approved the minutes of the July interim "email" meeting (Appendix A) with an amendment of the thiazolidinedione (TZD) section.

4. INTERIM DECISIONS/ADMINISTRATIVE ISSUES

The July interim "email" DoD Executive Council Meeting resulted in the following BCF and TMOP changes:

- Latanoprost (Xalatan) was added to the BCF
- Rosiglitazone (Avandia) was added to the BCF
- Rosiglitazone/metformin (Avandamet) was added to the BCF
- Serevent MDI was removed from the BCF due to market withdrawal. Serevent DPI will be the remaining salmeterol on the BCF.
- Zolmitriptan oral tablets (Zomig) were added to the BCF
- Sumatriptan oral tablets (Imitrex) were removed from the BCF
- Gefitinib (Iressa) was added to the TMOP with quantity limits
- Lovastatin extended release (Altocor) was removed from the TMOP

5. NATIONAL PHARMACEUTICAL CONTRACTS AND BLANKET PURCHASE AGREEMENT (BPA) AWARDS, RENEWALS AND TERMINATIONS

A. The next option years were exercised for the following contracts: fluoxetine, indomethacin, digoxin, naproxen, ointment base, captopril, paclitaxel injection, carbidopa/levodopa SA tablets, glyburide, amantadine, buspirone, benztropine.

B. New contracts were awarded for ketoconazole cream, midazolam, pamidronate injection and zolmitriptan.

6. PROCUREMENT INITIATIVES

A. Oral Fluoroquinolones, Angiotensin Receptor Blockers (ARBs), and Bisphosphonates –CDR Briski updated the Council on the progress of the oral fluoroquinolone, ARB and bisphosphonate solicitations.

B. 2nd Generation Antihistamines – Loratadine is available to MTFs at $0.38 per dose compared to fexofenadine at $0.85 per dose and cetirizine at $0.96 per dose. Although fexofenadine currently remains on the BCF, the termination of the fexofenadine contract allows MTFs to have additional non-sedating antihistamines on their formularies. Since loratadine is significantly less expensive than all other second generation antihistamines, MTFs are encouraged to add loratadine to their formularies and maximize the use of loratadine consistent with the clinical needs of patients. [Note: The Council could not add loratadine to the BCF because over-the-counter products are generally not allowed on the BCF.] Loratadine is currently on 52% of MTF formularies.

C. Novo Insulin Products – CAPT Torkildson presented information on two issues regarding the current contract with Novo Nordisk for regular, NPH, lente, and 70/30 insulin products.

1. The Council voted at its last meeting to recommend that DSCP not exercise the final option year on the insulin contract (which covers regular, NPH, 70/30 and lente insulin), and solicit a new contract this year. This recommendation was based on the increasing utilization of both ultra-short acting insulin and alternative insulin delivery systems, neither of which is covered by the current contract. Novo approached the PEC in mid-June with a proposal to lower the FSS price on their FlexPen disposable delivery systems and continue their temporary price reduction for Novolog vials (32% reduction from the FSS price) and Novolog 70/30 vials (53% reduction from FSS) in return for a decision to exercise the final option year of the contract. Since the last meeting the PEC also received information that a third company anticipates approval of their ultra-short acting insulin product early next year.

2. Shortly after its meeting with the PEC in mid-June, Novo notified the PEC that they planned to discontinue distribution of their lente insulin product in October 2003. Novo committed to providing lente insulin to their government clients at current levels through January 2004. An analysis of PDTS data revealed that only 271 patients filled prescriptions for lente insulin at MTFs and only 63 patients filled prescriptions for lente insulin in mail order during the 2nd quarter of FY2003. The number of patient utilizing lente insulin decreased by 50% over

the previous year. Although lente insulin is covered by the current insulin contract, the discontinuation of lente insulin will affect a relatively small number of patients.

The PEC recommended that the council reverse its previous decision and instead recommend that DSCP exercise the final year of the insulin contract and delay a resolicitation of the contract until summer 2004. The Council voted unanimously to exercise the final option year of the insulin contract and defer the resolicitation of insulin contract until next summer.

7. DRUG/DRUG CLASS EVALUATIONS

A. Oral Estropipate Hormone Replacement Therapy – Hormone replacement therapies currently available on the BCF include oral conjugated estrogens (Premarin), oral medroxyprogesterone, combination conjugated estrogen/medroxyprogesterone (Prempro), estrogenic vaginal cream (MTFs select the brand), and estradiol transdermal systems (Esclim). The Council considered oral estropipate for addition to the BCF as an alternative oral estrogen replacement therapy.

Efficacy/Safety/Tolerability – Studies have shown that the various oral estrogen replacement products are equally efficacious in treating postmenopausal symptoms. The labeling for all oral estrogen products contains the same safety warning for the risk of heart disease, stroke, and cancer. There is no evidence that the oral estrogen products differ in tolerability.

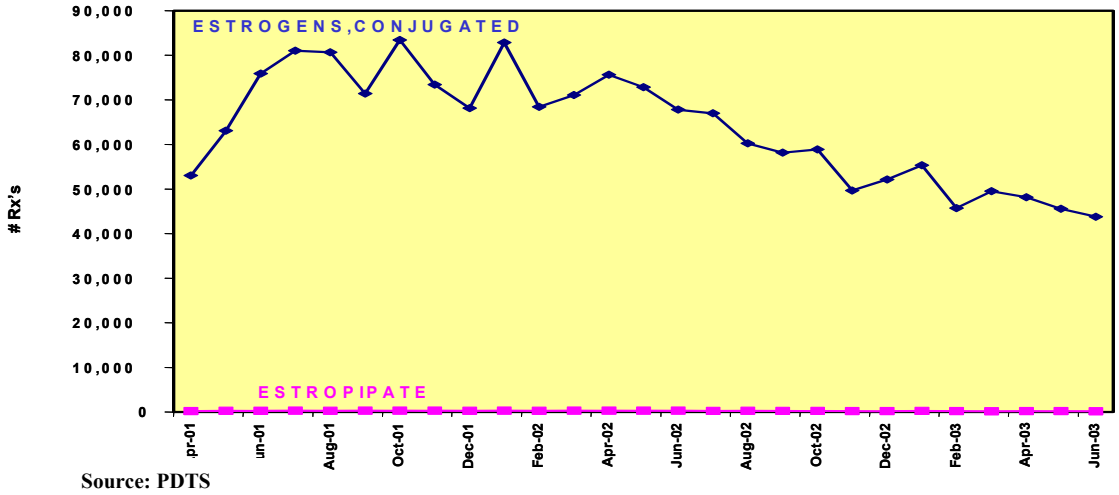
Table 1: Prime Vendor Weighted Average Cost/Tablet for Estropipate and Premarin

	Estropipate (Mylan)	**Estropipate (**Watson)	**Estropipate** (Ogen; Pharmacia & UpJohn	**Estropipate** (Ortho-est; WHFC)	**Conjugated Estrogen** (Premarin; Wyeth-Ayerst)
Prime Vendor Weighted Average Acquisition Cost/Tablet (June 2003)	$0.41	$0.11	$0.18	$0.19 (Was $0.42 prior to BPA initiated in June)	$0.23

Cost – Table 1 displays the prime vendor weighted average cost/tablet for various brands of estropipate and Premarin. Estropipate is available at a significantly lower cost than Premarin.

Other factors – The FDA and American College of Obstetricians and Gynecologists (ACOG) recommend starting women on low doses of estrogen in light of the Women's Health Initiative (WHI) study. Estropipate is not currently available in doses that are equivalent in estrogenic activity to the 0.3 mg and 0.45 mg strengths of Premarin.

Figure 1: MTF Oral Estrogen Rx Fills April 01 – June 03



Source: PDTS

Utilization – Figure 1 shows that MTFs use very little estropipate in comparison to Premarin. Only 20% of MTF formularies include estropipate compared to the 98% that include Premarin. Providers who were surveyed stated that the addition of estropipate to the BCF would not likely cause them to substantially increase their use of estropipate in lieu of Premarin.

The Council voted unanimously to not add an estropipate to the BCF because there is no evidence at this time that prescribers would be willing to use estropipate in lieu of Premarin.

B. *Dopamine Agonists* - The PEC is working with the VA on a joint review of the dopamine agonists. After the review is completed, the PEC will estimate the relative cost-effectiveness of the dopamine agonists and recommend which, if any, dopamine agonists, to add to the BCF.

C. *Isotretinoin*

Isotretinoin, a synthetic analogue of Vitamin-A, is indicated for the treatment of recalcitrant nodular acne. Available from Roche pharmaceuticals as Accutane® since 1982, isotretinoin recently became available as an AB-rated generic from three other manufacturers. The oral isotretinoin products available in the United States as of 1 July 2003 are listed in Table 2.

The Council considered an abbreviated PEC drug class review of isotretinoin for the purpose of deciding whether to pursue a sole-source contract (i.e. a contract to exclusively use a single brand of isotretinoin). Although sole-source contracts for "A-rated" generic equivalents do not typically require the review of the Council, an exception was made for isotretinoin because of its association with severe adverse events.

Table 2: Isotretinoin Products Available in the United States as of July 2003

Brand Name	Dosage Strengths	FDA approval date	Manufacturer
Accutane	10, 20, 40 mg	May 7, 1982	Hoffman – La Roche
Amnesteem	10, 20, 40 mg	Nov 15, 2002	Bertek
Sotret	10, 20, 40 mg	Dec 24, 2002	Ranbaxy labs
Claravis	10, 20, 40 mg	Apr 11, 2003	Barr

An average of 2,500 isotretinoin prescriptions are dispensed each month to DoD beneficiaries. Of these, approximately 1,500 are filled at MTFs and 1,000 through the retail network at costs of $342,000 and $221,000 respectively. The mail order system does not fill isotretinoin prescriptions because of the difficulty in meeting the requirements of the FDA mandated safety programs. The cost of a typical course of therapy for one person (15 weeks) is approximately $1,000 if the medication is dispensed through an MTF and $1,265 if the medication is dispensed through the retail network.

Efficacy/Safety – Isotretinoin has been on the market for over 20 years and remains the most efficacious treatment available for recalcitrant nodular acne. The main issue related to isotretinoin therapy is its potential to cause serious adverse effects, the most serious of which are birth defects and psychiatric disorders. In response to these adverse events, the FDA now requires that all isotretinoin therapy be administered in accordance with its strict risk management criteria.

Contracting Issues – The factors providing the impetus to pursue a sole-source contract for isotretinoin are its high cost, availability from multiple sources, and continued wide use within the MHS. The main issues to be addressed in pursuing a sole-source contract for isotretinoin include: (1) the interchangeability of the products, (2) the interchangeability of the risk management programs, and (3) the interchangeability of the prescription sticker programs.

1. Interchangeability of isotretinoin products: All four isotretinoin products available in the United States are AB-rated. By definition this means they are interchangeable.
2. Interchangeability of risk management programs: The FDA requires that the risk management programs for all isotretinoin manufacturers be the same. This is evident based on a statement by Janet Woodcock, Director of the Center for Drug Evaluation and Research, FDA that was found on the FDA web page: "All generic brands of isotretinoin will utilize the labeling that is alike in all material respects to the name brand, educational tools, and follow-up metrics in place under S.M.A.R.T." S.M.A.R.T. is the risk management program of the innovator company – Roche. To confirm this, written information included in three of the four risk management programs (SMART, SPIRIT, IMPART) were compared by members of the PEC and found to be identical in their wording. The risk management programs for each of the available products are listed in Table 3.
3. Interchangeability of prescription stickers: In a phone discussion with a Roche pharmaceutical representative regarding the interchangeability of isotretinoin

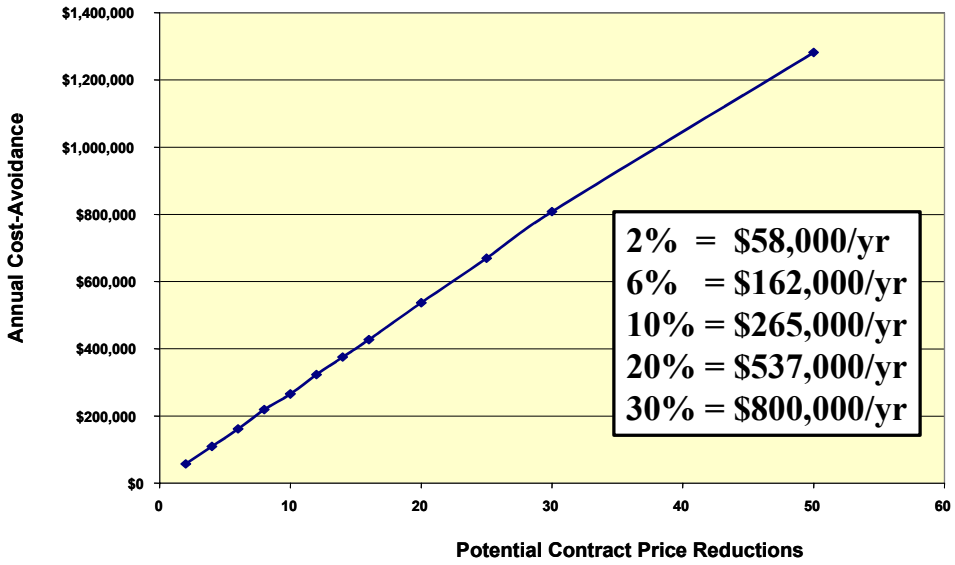
sticker programs, the following oral statement was provided: "Any AB-rated isotretinoin can be substituted for a prescription with an Accutane sticker and Accutane can be substituted for any prescription with an AB-rated isotretinoin sticker." Representatives from a state board of pharmacy (Texas) and the FDA concurred with this statement.

Table 3: Isotretinoin Risk Management Programs

Brand Name	Manufacturer	Safety Program
Accutane	Hoffman-La Roche	S.M.A.R.T. (System to manage Accutane related teratogenicity)
Amnesteem	Bertek	S.P.I.R.I.T. (System to prevent isotretinoin related issues of teratogenicity)
Sotret	Ranbaxy labs	I.M.P.A.R.T. (Isotretinoin medication program alerting you to the risks of teratogenicity)
Claravis	Barr	A.L.E.R.T. (Adverse event learning and education regarding teratogenicity)

Potential Cost-Avoidance – Figure 2 illustrates the cost-avoidance that would result from various price reductions that might be obtained with a sole-source contract for isotretinoin.

Figure 2: Isotretinoin cost avoidance from potential contract price reductions



The Council voted unanimously to support a sole-source contract initiative for isotretinoin that does not mandate addition of isotretinoin to the BCF.

8. REQUESTS FOR BCF CHANGES

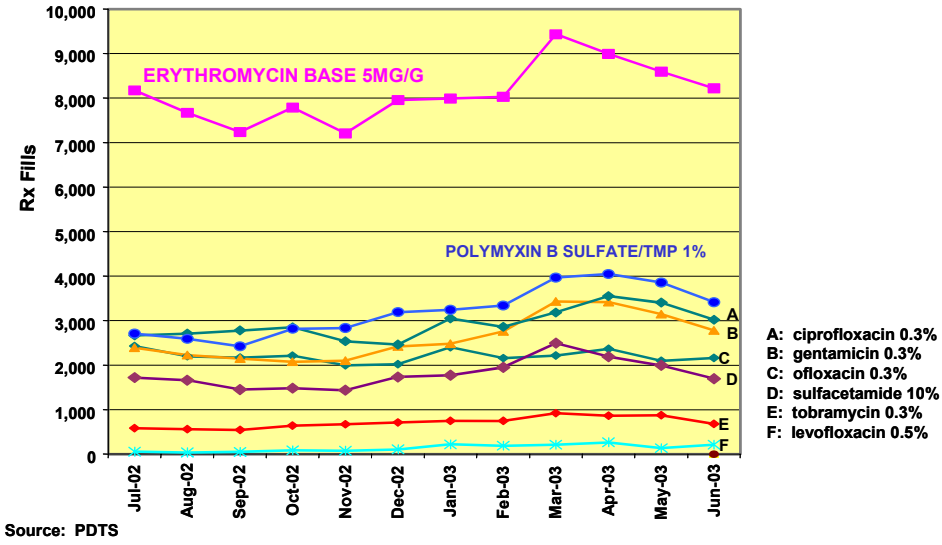
A. Ophthalmic Antibiotics – Polymyxin B Sulfate/Trimethoprim and Erythromycin

CDR Graham presented a recommendation from the PEC that polymyxin B sulfate/trimethoprim and erythromycin ophthalmic antibiotics be added to the BCF. This recommendation was based on two factors: 1) both are cost-effective alternatives compared to ophthalmic fluoroquinolones for primary care treatment of superficial ocular bacterial infections, including acute bacterial conjunctivitis and blepharoconjunctivitis, and 2) high utilization and formulary status in the MTFs.

Efficacy/Safety/Tolerability – Polymyxin B sulfate/trimethoprim and erythromycin have been proven efficacious in the treatment of superficial ocular infections involving the conjunctiva and/or cornea caused by susceptible organisms. Erythromycin is also safe and effective for the prophylactic treatment of ophthalmia neonatorum due to *Neisseria gonorrhoeae* or *Chlamydia trachomatis*. Safety and effectiveness of polymyxin B sulfate/trimethoprim are established down to the age of 2 months.

Cost – Both polymyxin B sulfate/trimethoprim and erythromycin are available as generics with respective costs of $1.19 – 1.52/10 ml vial and $0.99/3.5 gm tube, compared to fluoroquinolones starting around $14.00/5 ml.

Figure 3: MTF Rx Fills Ophthalmic Antibiotics July 02 – June 03



Source: PDTS

Utilization/MTF Formulary Status – Figure 3 shows current MTF utilization of polymyxin B sulfate/trimethoprim and erythromycin compared to other ophthalmic antibiotics. Over 80% of MTFs have both agents on their formulary.

The Council voted unanimously to add polymyxin B sulfate/trimethoprim ophthalmic solution and erythromycin ophthalmic ointment to the BCF.

B. Ultra-Short Acting Insulin Products

CAPT Torkildson and Ms. Angela Allerman presented a recommendation from the PEC that an ultra-short acting insulin product be added to the BCF. This recommendation was based on two factors: 1) the superior outcomes achieved with ultra-short acting insulin compared to regular insulin, and 2) the steadily increasing utilization of ultra-short acting insulin products in DoD.

Data were presented comparing the activity profiles of regular and ultra-short acting insulins. The more rapid onset of action, shorter time to peak activity, and shorter effective duration of action make the profile of ultra-short acting insulin more physiologic. Clinical trials demonstrate improved post-prandial glycemic control, lower HbA1c levels, and fewer episodes of post-prandial hypoglycemia with ultra-short acting insulins.

Data regarding the relative utilization of regular and ultra-short acting insulin at MTFs is presented in Table 4. The projected figures are based on the trend observed over the preceding 12 months. Based on these projections, the number of utilizers of ultra-short acting insulin products will exceed the number of regular insulin utilizers during the first quarter of FY 2004. Based on this information, the Council voted unanimously to accept the PEC's recommendation to add an ultra-short acting insulin to the BCF.

Table 4: Number of Unique Utilizers of Ultra-short Acting and Regular Insulin Products at MTFs

Quarter	Ultra-short Acting	Regular
Historical Figures		
2001, Q4	4,219	13,507
2002, Q1	4,784	13,210
2002, Q2	5,378	12,733
2002, Q3	6,055	12,289
2002, Q4	6,569	11,455
2003, Q1	7,456	11,316
2003, Q2	8,032	10,703
Projected Figures		
2003, Q3	8,638	10,248
2003, Q4	9,280	9,767
2004, Q1	9,922	9,285
2004, Q2	10,564	8,804
2004, Q3	11,206	8,322
2004, Q4	11,848	7,841

The presentation now turned to the question regarding which ultra-short acting insulin represented the most cost-effective choice for the direct care system. Data were first presented that addressed the therapeutic interchangeability, clinical coverage, and provider acceptance of Novolog and Humalog. The available data suggest no clinically relevant difference between the products' activity profiles. Although Novolog has an FDA-approved indication for use in insulin pumps and Humalog does not, several trials including a non-blinded head-to-head trial in pump patients suggest that the products are equally effective in improving post-prandial glucose control in this population. Anecdotal reports exist that suggest Novolog has greater stability and maintenance of potency in pumps, especially in warm climates, but this has not been scientifically evaluated as yet. There is no evidence for a difference in the number, type, or severity of adverse reactions seen with the two products. Therefore, either product appears to be suitable for use in diabetic patients. Either product could reasonably be expected to meet the clinical needs of the majority of patients requiring pre-prandial insulin therapy to control post-prandial hyperglycemia. Conversely, patients who failed to achieve the desired control with one of these products would be unlikely to achieve the desired control with the other.

Assessment of provider acceptance in this case was somewhat complex. As noted previously, Novo Nordisk currently has a contract to provide regular, NPH, and 70/30 mixed insulin to the DoD and VA. DoD compliance with this contract is fairly good, with about 75% of utilizers in each of these market baskets using the Novo product. However, < 3% of utilizers of ultra-short acting insulin use Novolog, despite an $8/vial cost difference in favor of Novolog. Additionally, at the time of the analysis Novolog was on formulary at only 4 MTFs throughout DoD. In a recent *PEC Update*, readers were asked to comment on why this situation existed. Responses indicated that several factors contributed to this: 1) Humalog was first to market and first on formulary (inertia); 2) providers considered the products to be clinically equivalent and were unaware of the price difference; and 3) Novolog was not on formulary at most facilities, and as the products were not seen as having substantial clinical differences providers had no motivation to push for its addition. Both junior and senior level endocrinologists expressed a willingness to change to the less expensive product, and one diabetic educator stated that she had unsuccessfully approached her local P&T Committee on three different occasions with evidence that substantial cost savings could be realized by making Novolog available to providers.

The following cost and utilization data were then presented. During the period 1 May 2002 through 30 April 2003, $3.2 million were spent on ultra-short acting insulin therapy by MTFs. Given the growing utilization of ultra-short acting insulin, it was projected that in FY 2004 MTFs would experience an 18.6% increase in the cost of ultra-short acting insulin therapy, to $3.8 million. However, given the current prices of the two products, if only 10% of the market was moved to Novolog the MTFs would experience instead a 2% decrease in the cost of therapy. If Novolog achieved a 50% market share, the overall cost would decrease by almost 15%, to $2.7 million, despite an almost 20% increase in utilization. The increase in

market share would also ensure that the Novolog prices would remain in place until the awarding of the new insulin contract next fall.

Based on these factors, the Council voted unanimously in favor of the PEC recommendation to add Novolog to the BCF, to have the PEC provide information to providers and facilities encouraging its use for the reasons noted, and to have the PEC provide additional information regarding the opportunity for facilities to achieve additional cost avoidance by evaluating the Novo FlexPen devices as an alternative to Humalog disposable syringes.

9. ADJOURNMENT

The meeting adjourned at 1400 hours. The next meeting will be held at Fort Sam Houston, TX at 0800 on Thursday, 13 November 2003. All agenda items should be submitted to the co-chairs no later than 06 October 2003.

3. NATIONAL PHARMACEUTICAL CONTRACT AWARD

The VA National Acquisition Center (NAC) recently awarded a joint VA/DoD triptan contract to Astra Zeneca for zolmitriptan. Per the terms of the contract, zolmitriptan replaces sumatriptan as the only oral triptan on the BCF effective 11 Jul 03. MTFs may have one oral triptan in addition to zolmitriptan on their local formularies. The contract does not affect the formulary status of non-oral triptan dosage forms. The PEC provided guidance to MTFs for implementing the zolmitriptan contract (see the National Contracts page on the PEC website). Sumatriptan injection will remain on the BCF.

4. PROCUREMENT INITIATIVES

A. Ophthalmic Prostaglandins – At the May DoD P&T Executive Council meeting the Council was informed that the VA and DoD would each pursue their own procurement strategies for ophthalmic prostaglandins. Pfizer has proposed a blanket purchase agreement (BPA) that reduces the price of latanoprost by 25% (price decreases from $28.89 to $21.67 per bottle) if latanoprost is added to the BCF and no other ophthalmic prostaglandins are included on the BCF. Latanoprost would be the sole ophthalmic prostaglandin on the BCF, but MTFs could have additional ophthalmic prostaglandins on their local MTF formularies. The Council voted unanimously to add latanoprost to the BCF and advise DSCP to approve the latanoprost BPA.

B. Thiazolidinediones (TZDs, "Glitazones") – The Council had previously authorized the addition of a single thiazolidinedione to the BCF using a procurement strategy that could include up to a joint DoD/VA closed class contracting strategy competing rosiglitazone and pioglitazone. Glaxo Smith Kline (GSK) has proposed a joint VA/DoD BPA that offers tiered pricing for rosiglitazone (Avandia) and the combination of rosiglitazone and metformin (Avandamet) based on their aggregate market share at MTFs if Avandia and Avandamet are the only thiazolidinediones on the BCF. The Avandamet BPA price equals the rosiglitazone BPA price plus the contract price for generic metformin. The BPA pricing will provide a 20% discount to DoD based on the 68% market share that rosiglitazone currently has at MTFs. Based on historical dose distributions, the 20% discount will reduce the average daily cost for rosiglitazone from $2.16 to $1.73. The average daily cost for pioglitazone is $2.41, which is 39% more per day than rosiglitazone.

Although the Council had not previously discussed the inclusion of Avandamet in the TZD procurement strategy, the Council determined that the addition of Avandamet was consistent with previous BCF decisions and would be a rational complement to Avandia on the BCF because:

- Metformin is appropriately and frequently used in combination with rosiglitazone (50% of current rosiglitazone users are also taking metformin).
- The Council has previously concluded that combination products may be more convenient for patients to take and may improve compliance compared to giving the same products separately.
- The Avandamet pricing is cost-neutral compared to the pricing for the separate products. Although DoD currently has a contract for metformin, there have been

supply problems that cause MTFs to make off-contract purchases of metformin at higher prices. To the extent that the use of Avandamet will reduce the use of off-contract metformin, DoD will realize a cost-benefit for those patients needing combination therapy.

The Council voted unanimously to add rosiglitazone (Avandia) and the combination of rosiglitazone and metformin (Avandamet) to the BCF and advise DSCP to approve the rosiglitazone BPA.

5. BCF AND TRICARE MAIL ORDER PHARMACY (TMOP) FORMULARY ISSUES

A. Gefitinib (Iressa) 250 mg tablets – Iressa is a new oral agent approved, 5 May 03, as monotherapy for locally advanced or metastatic non-small cell lung cancer (NSCLC) after failure of both platinum-based and docetaxel (Taxotere) chemotherapies (i.e. third-line treatment).

The Council unanimously voted to not add Iressa to the BCF, but to add Iressa to the TMOP Formulary with a quantity limit of 45 tablets per 45 days, to reduce wastage. Gefitinib is costly ($1168/month based on FSS pricing) and patients are likely to discontinue therapy (2/3 of the patients receiving therapy will be treated for no longer than 3 months), either due to death or lack of response. In addition, since the symptomatic benefit of gefitinib appears to correlate with tumor response rate and occurs early in treatment, it is rational to evaluate the patient within 6 weeks (clinical investigators maintain that four to six weeks of therapy is sufficient to test for response). It also appears reasonable to discontinue therapy in patients who are not benefiting.

B Statins – At the May 03 DoD P&T Executive Council meeting the Council voted to add Altocor to the TMOP Formulary. The PEC has subsequently been advised that the addition of Altocor to the TMOP formulary may violate the provisions of the Zocor contract.

The solicitation for the new stated in part, "The BCF and Mail Order Pharmacy Formulary will also contain a generic form of lovastatin and may contain one of the HMG-CoA agents not extensively metabolized by the cytochrome P450 (CYP) metabolic pathway (i.e. pravastatin or fluvastatin), but not both."

Although the solicitation did not specifically prohibit the inclusion of a brand name version of lovastatin on the TMOP formulary, the specific reference to inclusion of a generic form of lovastatin on the TMOP formulary could reasonably be construed to imply that a brand name version of lovastatin would not be included on the TMOP formulary.

The Council voted unanimously to remove Altocor from the TMOP formulary.

6. NEXT MEETING

The next meeting will be held at TRICARE Management Activity (TMA), conference room 815, Skyline Building 6, 5111 Leesburg Pike, Falls Church, VA at 0800 on Tuesday, 5 August 2003. All agenda items should be submitted to the co-chairs no later than 18 July 2003.

3. **REVIEW MINUTES OF LAST MEETING/ADMINISTRATIVE ISSUES** – The minutes from the last meeting were accepted as written.

4. **INTERIM DECISIONS** – No interim decisions.

5. **UNIFORM FORMULARY (UF) PROPOSED RULE**- COL William Davies, DoD Pharmacy Program Director, TMA, stated that the current plan is to implement the Uniform Formulary in conjunction with the TRICARE Retail Pharmacy contract. The proposed date for implementation of the Tricare Retail Pharmacy (TRRx) is April 2004.

6. **BCF AND TRICARE MAIL ORDER PHARMACY (TMOP) FORMULARY ISSUES** – The Committee determined the TMOP formulary status, TMOP or retail network formulary restrictions (quantity limits or prior authorization), and Basic Core Formulary (BCF) status for 6 new drugs or formulations (see Appendix A). The PEC also presented brief information on four additional new drugs or formulations not requiring a complete review by the Committee (see Appendix B). The Committee agreed that no further review was required.

7. MAIL ORDER AND RETAIL NETWORK ISSUES

A. *Statins* – The high potency statin contact was awarded to Merck for simvastatin (Zocor). The contract states that the BCF and Mail Order Pharmacy formulary will also contain a generic form of lovastatin and may contain one of the statins that is not extensively metabolized by the cytochrome P450 3A4 isoenzyme system. The Committee voted unanimously to add generic lovastatin, lovastatin extended release (Altocor), lovastatin/Niaspan (Advicor), and pravastatin (Pravachol) to the TMOP formulary.

B. *Guaifenesin* – At the November 2002 meeting, the P&T Committee was informed that:

> "As of 12 Jul 2002, Mucinex (Adams Labs) became the first single ingredient guaifenesin extended release product to be 1) approved as safe and effective under a New Drug Application (NDA) and 2) to be approved as an over-the-counter (OTC) product. As a consequence of approval, the FDA has sent warning letters to manufacturers of guaifenesin extended release products explaining that currently marketed single ingredient guaifenesin extended release products without an approved application are considered misbranded and in violation of section 505(a) of the Food, Drug, and Cosmetic Act (FDCA). In addition, provisions of the Durham-Humphrey amendment (products cannot be marketed as both Rx and OTC products) effectively mean all single ingredient extended release will be OTC products. At least one affected manufacturer is known to be petitioning this action, but it is not known if any single ingredient guaifenesin extended release product other than Mucinex will continue to be available in the near future. *Since single ingredient guaifenesin extended release products are now OTC products, they will no longer be available from the NMOP and will not be included on the NMOP Formulary. Prescription extended release guaifenesin products will be dispensed by the NMOP as long as current supplies permit.*" (Emphasis added)

The FDA subsequently issued a letter to manufacturers in February 2003 that allowed them to continue manufacturing guaifenesin extended release products until 21May 2003 and continue distribution of such products until 23 October 2003. In the absence of additional actions on this matter, it is expected that legend extended release guaifenesin products will be available until early November 2003.

In light of the FDA's action, the Committee clarified the status of guaifenesin on the TMOP formulary. Single ingredient guaifenesin extended release products will remain on the TMOP formulary and be dispensed from the TMOP as long as they are available as legend drugs.

C. *Legend Vitamins* – Several questions have arisen recently regarding the availability of legend vitamins from the TMOP. According to Chapter 7 of the TRICARE Policy Manual, "Vitamins may be cost-shared only when used as a specific treatment of a medical condition." Operationally, the question is "do all prescriptions for vitamins require an individual determination that they meet the above requirement? Conversely, can prescriptions for certain vitamins be determined to be covered by virtue of their FDA-approved indications and the lack of a potential for off-label use that would not meet the above requirement?" An example of such a product would be a combination of

folic acid, cobalamin (B12) and pyridoxine (B6), indicated as "treatment for hyperhomocysteinemia, homocystinuria, dialysis, end stage renal failure and in conditions associated with cardiovascular disease, cerebrovascular disease, and peripheral vascular disease." The single MCSC pharmacy representative present at the meeting indicated that in his region, phone calls are made on all vitamin prescriptions to verify compliance with the above requirement, except in the case of prenatal vitamins prescribed to women under the age of 45, which are presumed to be medically necessary. This exception is based on a decision made by the DoD P&T Committee in July 1998 to continue to provide prenatal vitamins to females under the age of 45 without a requirement to document pregnancy.

The subsequent discussion focused on how to make the determination that vitamins are being prescribed for a specific medical condition. The TMA General Counsel advised that in general this would be an administrative decision that would be handled as a collaborative effort of Express Scripts, the PEC, and the TMA General Counsel. In most cases the P&T Committee would not be involved in this process, but in some circumstances the Committee might determine that a particular legend vitamin product, by virtue of its FDA-approved indication(s) and a low probability of use that would not be covered by TRICARE, could appropriately be placed on the TMOP formulary. He recommended that in that case a specific statement be included in the minutes stating the specific intended use of the product. The Committee took no further action at this time.

D. "*Line extension" rules for the TMOP* –At the last meeting, the Committee asked for a review of the "line extension" rules for the TMOP, which provide for availability of generic equivalents, new dosage forms, and new formulations of products already on the TMOP formulary without a formal Committee decision. These rules were carried over from the previous National Mail Order Pharmacy (NMOP) program, but there are operational differences between the two programs that affect the manner in which the rules are applied.

For the NMOP program, the mail order contractor (Medco) maintained the file of available items and was responsible for applying line extension rules to determine inclusion or exclusion of new products, along with the NMOP Contracting Officer's Technical Representative (COTR). New molecular entities and other products requiring Committee approval were not added to the file of available items until publication of the minutes of the Committee meeting in which they were approved.

For the TMOP program, the task of maintaining computerized rules defining which items are available through the TMOP now rests with WebMD as a part of the Pharmacy Data Transaction Service (PDTS). Instead of a file of available items, those items not included in the TMOP Formulary are "blocked" using a combination of First Data Bank categories and drug classification codes. Accordingly, it is necessary to review the addition of new products to First Data Bank on an ongoing basis in order to identify new molecular entities and other products that require Committee review. This is now being accomplished by the PEC on a weekly basis, with approval by the TMOP Contracting Officer's Representative (COR).

The Committee approved the line extension rules outlined below. The Committee noted that these are guidelines rather than absolute rules, acknowledging the need for the PEC

and TMOP COR to use their judgment to deal with circumstances not covered by the rules:

- Medications outlined below are added to the TMOP Formulary without formal action by the DoD P&T Committee unless the PEC or TMOP COR identifies a reason for the P&T Committee to be involved in the decision:
  - Generic equivalent, new dosage form, or new formulation of an agent already on the TMOP Formulary
  - New drug entity in a therapeutic class/category for which the Committee has previously approved automatic inclusion for new drug entities. Currently the only drug class to which this applies is AIDS/HIV drugs. The Committee will review drugs automatically included under this provision at the next scheduled meeting.
  - New combination products of medications that are already on the TMOP Formulary.

8. **CONTROLLED DISTRIBUTION OF PRESCRIPTION DRUGS** – Buprenorphine and buprenorphine/naloxone (Subutex/Suboxone) were recently approved for the treatment of opioid dependence and are subject to a controlled distribution process. Subutex/Suboxone are NOT a covered benefit under TRICARE rules. Champus Basic Program benefits; Part 199.4 states: "Drug maintenance programs when one addictive drug is substituted on a maintenance basis (such as methadone substituted for heroin) are not covered. This exclusion applies even in areas outside the United States where addictive drugs are dispensed legally by physicians on a maintenance dosage level."

9. **ADJOURNMENT –** The meeting adjourned at 1030 hours. The next meeting will be held at TRICARE Management Activity (TMA), conference room 815 Skyline Building 6, 5111 Leesburg Pike, Falls Church, VA at 0800 on Wednesday, 6 August 2003. All agenda items should be submitted to the co-chairs no later than 18 July 2003.

List of Appendices

APPENDIX A: NEWLY APPROVED DRUGS CONSIDERED FOR THE TRICARE MAIL ORDER PHARMACY (TMOP) FORMULARY AND THE DOD BASIC CORE FORMULARY (BCF)

Generic name (Trade name; manufacturer)	**FDA approval date, drug class, FDA-approved indication**	**TMOP Formulary status**	**TMOP and/or retail network formulary restrictions**	**BCF status**
Estradiol acetate vaginal ring (Femring; Galen)	24 Mar 03: Indicated for the treatment of moderate to severe vasomotor symptoms associated with menopause as well as symptoms of vulvar and vaginal atrophy. The ring is designed for self-insertion and delivers a steady estrogen dose for 3 months. Two doses: 50 or 100 mcg released daily.	Added to the TMOP Formulary	**Quantity Limits** General rule applies **Prior Authorization:** None	Not added to the BCF **Similar BCF agents:** None
Pegvisomant injection (Somavert; Pfizer)	04 Apr 03: Growth hormone receptor antagonist indicated for the treatment of patients with acromegaly who have failed to respond to currently available therapies, such as surgery, radiation therapy, or other medical therapies, or for whom these therapies are not appropriate. Decreases insulin-like growth factor-1 (IGF-1) concentrations As an orphan drug, usage of this product is expected to be infrequent; however, the product is listed in First Data Bank and ESI anticipates no difficulty obtaining it for patients using the TMOP.	Added to the TMOP Formulary & TMOP Covered Injectables List Intended for self-administration; daily subcutaneous injections; must be refrigerated	**Quantity Limits** General rule applies **Prior Authorization** None	Not added to the BCF **Similar BCF agents:** None
Gatifloxacin ophthalmic solution (Zymar; Allergan)	31 Mar 03: 0.3% solution is indicated for treating bacterial conjunctivitis caused by susceptible strains of bacteria	Added to the TMOP Formulary	**Quantity Limits** General rule applies **Prior Authorization** None	Not added to the BCF **Similar BCF agents**: None
Cyclosporine ophthalmic solution 0.05% (Restasis; Allergan)	29 Jan 03: 0.05% solution is indicated to increase tear production in patients whose tear production is presumed to be suppressed due to ocular inflammation associated with keratoconjunctivitis sicca (KCS)	Added to the TMOP Formulary	**Quantity Limits** General rule applies **Prior Authorization** None	Not added to the BCF **Similar BCF agents**: None

Generic name (Trade name; manufacturer)	**FDA approval date, drug class, FDA-approved indication**	**TMOP Formulary status**	**TMOP and/or retail network formulary restrictions**	**BCF status**
Aprepitant capsules (Emend; Merck)	26 Mar 03 (priority review): A substance P / neurokinin 1 (NK1) receptor antagonist indicated for use in combination with other antiemetic agents for preventing acute and delayed nausea and vomiting associated with highly emetogenic cancer chemotherapy (including high-dose cisplatin). First medication specifically labeled for delayed nausea and vomiting. 125 mg dose on day 1 (1 hour prior to chemotherapy), followed by 80 mg QAM on days 2 and 3. Still requires concomitant administration of ondansetron and dexamethasone	Added to the TMOP Formulary	**Quantity Limits** Rationale for the quantity limits includes the potential for inappropriate use and wastage, FDA requirement for the manufacturer to monitor off label uses; and existing quantity limits for 5-HT3 antagonists. Quantity limits are set to provide for the possibility that chemotherapy is on a 3-week cycle, rather than once per month. Most patients will require less. Packaged in convenience packs (one 125 mg; two 80 mg capsules) and in 30-count bottles **Retail:** Convenience packs: 2 packs per 30 days; 125 mg caps: 2 per 30 days; 80 mg caps: 4 per 30 days **TMOP**: Convenience packs: 6 packs per 90 days; 125 mg caps: 6 per 90 days; 80 mg caps: 12 per 90 days **Prior Authorization** None	Not added to the BCF **Similar BCF agents:** None
Enfuvirtide injection (Fuzeon; Roche/ Trimeris)	13 Mar 03 (accelerated approval). New modality for treating HIV (fusion inhibitor) that blocks the interaction of HIV with CD4+ cells. Indicated for use in combination with other antiretroviral agents for treatment-experienced patients with evidence of HIV-1 replication despite ongoing antiretroviral therapy. Product is self-administered SQ BID, and is available in a convenience kit of 60 vials with supplied diluent. Complicated 100-step manufacturing process has resulted in a limited supply for about 12,000-15,000 patients worldwide. Product will be allotted on a first-come, first-serve basis through a sole distributor, Chronimed. Physicians must enroll patients via fax. Details on the Fuzeon Progressive Distribution Program may be found at www.fuzeon.com. Anticipated yearly cost is $20,000.	Not added to the TMOP Formulary & Covered Injectables List. Due to the restricted distribution process, ESI and the PEC will look into the feasibility of supplying enfuvirtide through the TMOP and readdress the issue at the August DoD P&T Committee meeting	**Quantity Limits** Patient needs are established as part of the distribution process; no specific quantity limits are needed. **Prior Authorization** None	Not added to the BCF **Similar BCF agents**: None

APPENDIX B: NEWLY APPROVED DRUGS NOT REQUIRING FULL REVIEW BY THE P&T COMMITTEE

Generic name (Trade name; manufacturer)	**Comments**
Isotretinoin capsules (Claravis; Barr)	AB rated generic to Accutane (Roche brand of isotretinoin). Not added to the TMOP Formulary because isotretinoin is excluded from the TMOP Formulary due to controlled distribution requirements. Generics from Bertek (Amnesteem) and Ranbaxy (Sotret) were evaluated in Mar 2003.
Conjugated estrogen/medroxyprogesterone acetate (Prempro 0.45/1.5; Wyeth)	Low-dose formulation of Prempro contains 0.45 mg of estrogen, and 1.5 mg of progestin (instead of 0.625 / 2.5 mg). Automatically added to TMOP as a line extension. Prempro is on the BCF.
Propranolol extended release capsules (InnoPran XL; Reliant)	Indicated for hypertension; the only beta-blocker formulation specifically indicated for QHS dosing. This product was approved under an NDA and is not a generic equivalent to the other propranolol extended release product, Inderal LA (Wyeth). Generic equivalents to Wyeth's Inderal LA have been discontinued. Innopran XL is available in 80 and 120 mg capsules; Inderal LA in 60, 80, 120 and 160 mg capsules. Automatically added to TMOP as a line extension. Not considered for BCF addition, since the other propranolol extended release product was removed from the BCF in Nov 1999 due both to limited supply (both Inderal LA and generics were manufactured by Wyeth) and low usage in DoD.
Metformin extended release tablets 750 mg (Glucophage XR; Bristol-Meyers Squibb)	Automatically added to TMOP as a line extension. Not considered for the BCF since extended release metformin is specifically excluded from the existing BCF listing for immediate release metformin.

APPENDIX C: COMBINED SUMMARY OF FORMULARY CHANGES FROM THE DOD P&T EXECUTIVE COUNCIL MEETING AND THE DOD P&T COMMITTEE MEETING

1. **BCF CHANGES**

   A. *Additions to the BCF*

      1) Estradiol transdermal system (Esclim)
      2) Risperidone (Risperdal)
      3) Quetiapine (Seroquel)
      4) Pimecrolimus cream (Elidel)
      5) Nitroglycerin patches (Nitrodur) [Schering brand per existing VA/DoD contract]
      6) Isosorbide mononitrate sustained release [Schwarz Pharma brand per existing VA/DoD contract]

   B. *Deletions, changes, clarifications or exclusions from the BCF* - None

2. **TMOP FORMULARY CHANGES**

   A. *Additions to the TMOP Formulary*

      1) Estradiol acetate vaginal ring (Femring; Galen)
      2) Pegvisomant injection (Somavert; Pfizer) – added to the TMOP Covered Injectables List
      3) Gatifloxacin ophthalmic solution (Zymar; Allergan)
      4) Cyclosporine ophthalmic solution (Restasis; Allergan)
      5) Aprepitant capsules (Emend; Merck) – quantity limits apply, see below
      6) Pravastatin
      7) Lovastatin
      8) Lovastatin extended release (Altocor)
      9) Lovastatin/niacin extended release combination (Advicor)

   B. *Exclusions from the TMOP Formulary* - None

   C. *Deletions, changes, or clarifications to the TMOP Formulary* - None

3. **QUANTITY LIMIT CHANGES (RETAIL NETWORK AND TMOP)**

   A. Quantity limit for aprepitant (Emend; Merck):

      - Convenience packs (convenience packs contain one 125 mg capsule and two 80 mg capsules): 2 packs per 30-day supply (Retail); 6 packs per 90-day supply (TMOP)
      - 80 mg capsules: 4 capsules per 30 days (Retail); 12 capsules per 90 supply (TMOP)
      - 125 mg capsules: 2 capsules per 30 days (Retail); 6 capsules per 90-day supply (TMOP)

4. **CHANGES TO THE TMOP PRIOR AUTHORIZATION PROGRAM** - None

Department of Defense
Pharmacoeconomic Center

2421 Dickman Rd., Bldg. 1001, Rm. 310
Fort Sam Houston, TX 78234-5081

MCCS-GPE **6 May 2003**

MEMORANDUM FOR: Executive Director, TRICARE Management Activity (TMA)

SUBJECT: Minutes of the Department of Defense (DoD) Pharmacy and Therapeutics (P&T) Executive Council Meeting

1. The DoD P&T Executive Council met from 0800 to 1500 hours on 6 May 2003 at the DoD Pharmacoeconomic Center, Fort Sam Houston, Texas.

2. VOTING MEMBERS PRESENT

CDR Terrance Egland, MC	DoD P& T Committee Co-chair
COL Daniel D. Remund, MS	DoD P& T Committee Co-chair
COL Joel Schmidt, MC	Army
COL Doreen Lounsbery, MC	Army
MAJ Travis Watson, MS	Army
COL John R. Downs, MC	Air Force
COL Mark Nadeau, MC (For COL Bill Sykora, MC)	Air Force
LtCol Ed Zastawny, BSC (For LtCol George Jones, BSC)	Air Force
CDR (sel) Debra Arsenault, MC (For CAPT Matt Nutaitis, MC)	Navy
CDR Mark Richerson, MSC	Navy
CAPT Robert Rist	Coast Guard
Mike Valentino	Department of Veterans Affairs

VOTING MEMBERS ABSENT

None	

OTHERS PRESENT

COL William Davies, MS	DoD Pharmacy Program Director, TMA
Howard Altschwager	Deputy General Counsel, TMA
CAPT Betsy Nolan, MSC (via VTC)	Navy Pharmacy Specialty Leader
COL Mike Heath, MS (via VTC)	Army Pharmacy Consultant Chair, DoD Pharmacy Board of Directors
COL Ardis Meier, BSC (via VTC)	Air Force Pharmacy Consultant
MAJ John Howe, BSC	Defense Supply Center Philadelphia
CAPT Joe Torkildson, MC	DoD Pharmacoeconomic Center
LTC Don DeGroff, MS	DoD Pharmacoeconomic Center
CDR Denise Graham, MSC	DoD Pharmacoeconomic Center
CDR (sel) Ted Briski, MSC	DoD Pharmacoeconomic Center
LtCol Dave Bennett, BSC	DoD Pharmacoeconomic Center
LtCol Barb Roach, MC	DoD Pharmacoeconomic Center
Shana Trice	DoD Pharmacoeconomic Center
Dave Bretzke	DoD Pharmacoeconomic Center
Angela Allerman	DoD Pharmacoeconomic Center
Eugene Moore	DoD Pharmacoeconomic Center
MAJ Mike Terry, BSC	TRICARE Southwest
Mark Geraci	Department of Veterans Affairs, PBM
LTC Marc Caouette, MS	Joint Readiness Clinical Advisory Board

3. REVIEW MINUTES OF LAST MEETING

The Council approved the minutes of the last meeting with a correction in the last sentence of the fourth paragraph in section 9A:

- Incorrect sentence: MTFs are currently spending nearly $100,000 per month on cholinesterase inhibitors.
- Corrected sentence: MTFs are currently spending nearly $326,000 per month on cholinesterase inhibitors.

4. ADMINISTRATIVE ISSUES

None

5. NATIONAL PHARMACEUTICAL CONTRACTS AND BLANKET PURCHASE AGREEMENT (BPA) AWARD, RENEWALS AND TERMINATIONS

A. The next option years were exercised for the following contracts: oral contraceptives, ticlopidine, valproic acid, nicotine patches, insulin syringes, isosorbide mononitrate, and capsaicin cream.

B. Proposals are being evaluated for the awarding of contracts to procure a sole source of isosorbide dinitrate, tramadol, ketoconazole cream, midazolam, and pamidronate injection.

C. DoD accepted an incentive agreement for methylphenidate (Concerta) that will reduce the price below FSS if performance incentives are met by the government.

6. PROCUREMENT INITIATIVES

A. *Ophthalmic Prostaglandins* – The Council had previously authorized the addition of an ophthalmic prostaglandin to the BCF using a procurement strategy that could include up to a joint DoD/VA closed class contracting strategy competing latanoprost, bimatoprost and travoprost, which would not require patients to be switched from one agent to another. The Federal Pharmacy Executive Steering Committee's (FPESC) subcommittee for contracting determined that a joint DoD/VA closed class contract would not meet the needs of both agencies. Each agency will pursue its own procurement strategy.

B. *Second Generation Antihistamines* –The availability of loratadine to MTFs at $0.38 per dose compared to fexofenadine at $0.60 per dose under a joint DoD/VA contract precipitated the decision to not renew the next option year of the fexofenadine contract. Although fexofenadine currently remains on the BCF, the termination of the fexofenadine contract allows MTFs to have additional non-sedating antihistamines on their formularies. Since loratadine is significantly less expensive than all other second generation antihistamines, MTFs are encouraged to add loratadine to their formularies and maximize the use of loratadine consistent with the clinical needs of patients. [Note: The Council could not add loratadine to the BCF because over-the-counter (OTC) products are generally not allowed on the BCF.]

C. *Thiazolidinediones (TZDs, "Glitazones")* – The Council had previously authorized the addition of a single thiazolidinedione to the BCF using a procurement strategy that could include up to a joint DoD/VA closed class contracting strategy competing rosiglitazone and pioglitazone. The contracting subcommittee of the Federal Pharmacy Executive Steering Committee is evaluating which procurement strategy would be the most cost-effective and meet each agency's requirements.

D. *Oral Fluoroquinolones* – The Council previously voted to support a joint DoD/VA contract for a "workhorse" fluoroquinolone that would compete levofloxacin and gatifloxacin. Two changes have occurred since that time:

   1) Ortho McNeil raised the price of levofloxacin by almost 40% effective 1 May 2003, and then repealed the price increase. Levofloxacin has been the only oral fluoroquinolone on the BCF for the past several years.

   2) Moxifloxacin recently gained FDA approval for treatment of community acquired pneumonia (CAP).

   The Council reviewed the most current clinical data including efficacy and safety/tolerability of levofloxacin, gatifloxacin and moxifloxacin.

   Efficacy – CAP and urinary tract infections (UTIs) are the primary indications for which fluoroquinolones are currently used. Gatifloxacin and moxifloxacin have broader gram-positive coverage and reduced gram-negative coverage than levofloxacin. All three agents are indicated for the treatment of CAP, chronic bronchitis, acute sinusitis and uncomplicated skin and skin structure infections. In addition, levofloxacin and gatifloxacin have an FDA indication for UTIs (however gatifloxacin will normally only cover approximately 80% of UTI infections because it has less gram-negative coverage). Moxifloxacin is not indicated for treatment of UTIs, which is attributed to less gram-negative coverage and extensive metabolism prior to excretion.

Safety/Tolerability – Adverse events of note include:

1) QTc prolongation with the subsequent potential for *torsade de pointes*. *Torsade de pointes* has been reported in 2 of 1,300,000 gatifloxacin patients, and 1 of 1,000,000 levofloxacin patients. Phase II-IV studies of moxifloxacin treatment in over 7,900 patients resulted in no cardiovascular morbidity attributable to QTc prolongation.
2) Dysglycemia has been associated with the use of gatifloxacin in diabetic patients receiving oral hypoglycemic agents or insulin, and elderly patients (>75yrs) with underlying disease states that increase the risk for dysglycemia.

Infectious Disease consultants stated the concerns regarding QTc prolongation and dysglycemia are probably "over-stated." However, providers should exercise caution when using fluoroquinolones in specific patients with underlying risk factors.

The Council concluded that fluoroquinolones are not sufficiently interchangeable to support a closed class contract. Differences in coverage and safety/tolerability concerns prevent the use of a single agent for all patients. All three fluoroquinolones will provide adequate clinical coverage for the majority of CAP and acute sinusitis infections.

The Council unanimously voted to authorize a procurement strategy that could include up to a joint DoD/VA open class contract competing moxifloxacin, gatifloxacin, and levofloxacin as a "workhorse" fluoroquinolone for the treatment of CAP and acute sinusitis.

E. *5HT1 Agonists (Triptans)* – The joint DoD/VA solicitation closed on 20 December 2002. The Government Accounting Agency (GAO) resolved a protest by ruling in favor of the Government. Detailed MTF guidance will be available on the PEC website when the contract award is announced.

F. *Angiotensin Receptor Blockers (ARBs)* – The Council had previously authorized the addition of a single ARB to the BCF using a procurement strategy that could include up to a joint DoD/VA closed class contract. The VA has determined that two ARBs should be on the VA National Formulary (VANF). The Council voted unanimously to accept two contracted ARBs for inclusion on the BCF. The change is expected to have minimal economic impact to DoD, while enhancing the ability of MTFs to effectively treat a wider range of patients using formulary ARBs.

G. The Council was updated on the progress of the bisphosphonate and insulin pen procurements.

7. DRUG/DRUG CLASS EVALUATIONS

A. *Transdermal Estrogen Preparations* – Short-term estrogen therapy remains the gold standard for relief of menopausal symptoms. Oral and transdermal routes are the most frequently used, with oral conjugated estrogens as the most popular estrogen formulation in the DoD and United States. Seven estrogen patches, all containing estradiol in varying strengths, are available in the United States (see Table 1). Currently the BCF contains oral conjugated estrogen, medroxyprogesterone, combination conjugated estrogen/medroxyprogesterone (Prempro), and an estrogenic vaginal cream (MTFs' choice). The BCF does not include an estrogen patch.

Table 1: Estradiol Transdermal Systems Available in the U.S.

Product/ Distributor	Release rate (mg/24 hr)	*Surface area (cm^2)	Delivery System/ Frequency of Administration
Vivelle-Dot Novartis	0.025; 0.0375; 0.05; 0.075; 0.1	2.5; 3.75; 5; 7.5; 10	Matrix Twice weekly
Vivelle Novartis;	0.025; 0.0375; 0.05; 0.075; 0.1	7.25; 11; 14.5; 22; 29	Matrix Twice weekly
Esclim Women First Health	0.025; 0.0375; 0.05; 0.075; 0.1	11; 16.5; 22; 33; 44	Matrix Twice weekly
Alora Procter & Gamble	0.05; 0.075; 0.1	18; 27; 36	Matrix Twice weekly
Climara Berlex	0.025; 0.05; 0.075; 0.1	6.5; 12.5; 18.75; 25	Matrix Once a week
♦**Estraderm** Ciba	0.05; 0.1	10; 20	Alcohol reservoir Twice weekly
Estradiol Mylan	0.05; 0.1	15.5; 31	Matrix Once a week
CombiPatch Aventis	0.05 mg estradiol/ 0.14 mg norethindrone acetate; 0.05 mg estradiol/ 0.25 mg norethindrone acetate	16	Twice weekly

*patch size increases with strength;
♦all drug delivery systems are matrix with the exception of Estraderm which uses an alcohol reservoir

Efficacy – All transdermal estrogen systems substantially decrease the number of hot flashes per week. There is no evidence that one estrogen compound is more effective than another. For relief of postmenopausal vasomotor symptoms, any patch can cover the clinical needs of patients; however, those providing the lowest dose with a wide range of dosing options are preferred by providers.

Safety/Tolerability – All estrogen-containing product package inserts carry an identical safety warning for the risk of heart disease, stroke, and cancer. Oral estrogen requires higher doses than transdermal estrogen. A recent trial assessing changes in C-reactive protein (CRP), a marker for inflammation in blood vessels and cardiovascular risk, suggested that transdermal systems might decrease cardiovascular adverse effects of estrogen. Patients using transdermal systems showed no elevation in CRP levels, while oral estrogens increased CRP levels two-fold.

Tolerability issues associated with the systemic effects of estrogen are similar for patches and oral estrogen. Local reactions due to transdermal patches include burning, erythema, irritation, pruritis, and rash. Reactions to the application site occur in about 10% of women who use reservoir (alcohol-based) patches and in 5% of women utilizing the matrix system. The incidence of skin irritation diminishes when the application site is rotated.

Table 2: Prime Vendor Cost for Transdermal Estrogen Systems

	Vivelle-Dot Novartis	**Vivelle** Novartis	**Alora** P&G	**Climara** Berlex	**Estraderm** Ciba	**Estradiol** Mylan
Prime Vendor Weighted Average Acquisition Cost/Patch	$2.20	$1.81	$1.40	$1.92	$1.96	$2.93
Dosage Frequency	Twice a week	Twice a week	Twice a week	Once a week	Twice a week	Once a week
Monthly Cost	$17.60	$14.48	$11.20	$7.68	$7.84	$23.44

Cost – Table 2 displays the prime vendor cost for various transdermal estrogen systems. Women's First Healthcare has offered a blanket purchase agreement that will make their estradiol patch (Esclim) available at a significantly lower monthly cost than other transdermal estrogen products if Esclim is added to the BCF.

Other factors – Esclim has better adhesiveness than Estraderm, which is currently on 75% of MTF formularies. The percentage of transdermal systems that became detached in the Esclim group was 6% compared to 11.3% in the Estraderm group ($p< 0.001$). (Maturitas 1996; 25)

The Council voted unanimously to add Esclim to the BCF. This will result in uniform availability of a transdermal estrogen product at a substantially reduced monthly cost per patient.

B. *Atypical Antipsychotics*

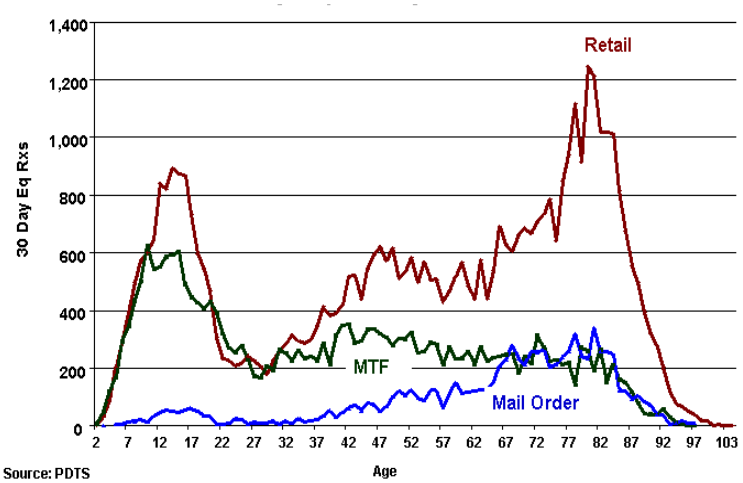
The Council considered a PEC drug class review of five atypical antipsychotics: aripiprazole (Abilify), olanzapine (Zyprexa), quetiapine (Seroquel), risperidone (Risperdal), and ziprasidone (Geodon). The review did not include clozapine (since its significant risk of agranulocytosis and requirement for routine white blood cell monitoring limit its use) or the injectable formulation of ziprasidone (an immediate release medication not intended for chronic use).

All five agents are indicated for schizophrenia; olanzapine is also indicated for acute bipolar mania. Other uses include depression with psychosis; symptoms of dementia including agitation, hyperactivity, hallucinations, suspiciousness, hostility and uncooperativeness; anxiety disorders; developmental disorders; autism; aggression/self injurious behavior; and Tourette's syndrome. Many of the atypical antipsychotics have been studied in pediatric as well as adult populations, although none of the drugs have pediatric indications. The review categorized the uses for atypical antipsychotics into four groups: schizophrenia and related psychoses, behavioral and psychological symptoms of dementia (BPSD), bipolar mania, and psychiatric and behavioral disorders in children and adolescents.

The onset of both schizophrenia and bipolar disorder is typically in early adulthood, between the late teens and mid-30s for schizophrenia, and in the early 20s for bipolar disorder. Based on the age distribution of usage in DoD (see Figure 1) and the likelihood that individuals with severe psychiatric illnesses will be required to leave the military, it

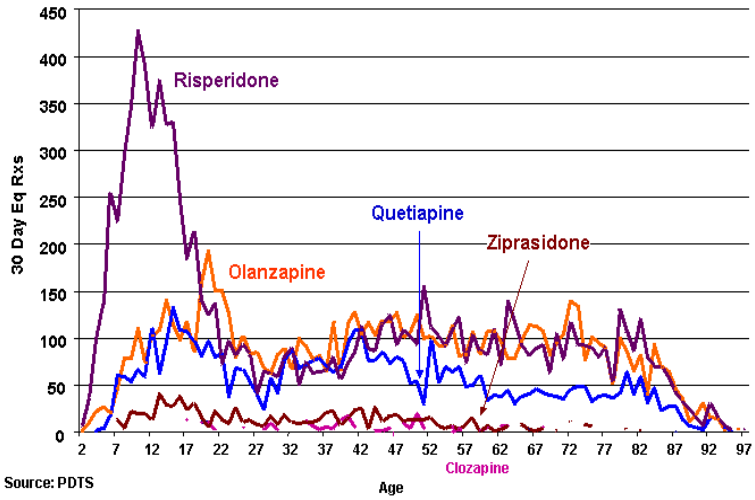
appears probable that uses other than schizophrenia or bipolar disorder represent a substantial proportion of atypical antipsychotic prescriptions in all three points of service.

Figure 1: Age Distribution of Atypical Antipsychotics in DoD
By 30 Day Equivalent Rxs, Oct 02 – Dec 02



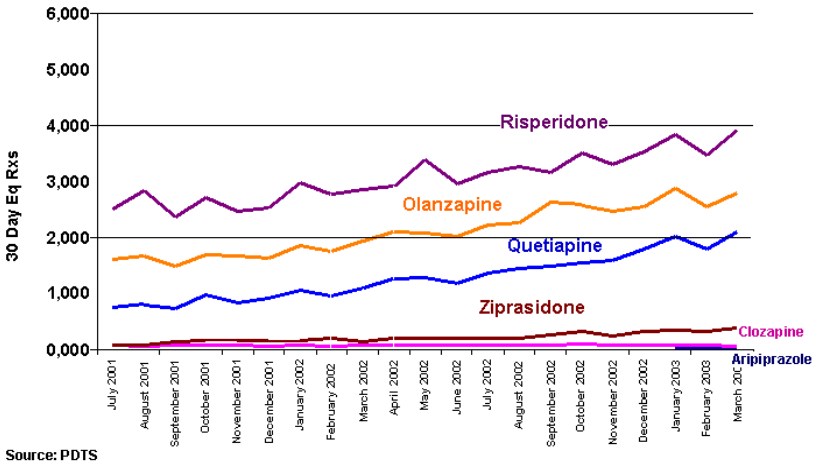
Individual atypical antipsychotics show distinctly different patterns of use at MTFs. As shown in Figure 2 below, risperidone is by far the most commonly prescribed agent in the pediatric population, although there is some usage of other atypical antipsychotics. Olanzapine, quetiapine, and risperidone show similar patterns of use in adult patients, although there is less use of quetiapine overall. Ziprasidone use appears to be less frequent in older patients. Aripiprazole was not yet available during the time period studied.

Figure 2: Age Distribution of Atypical Antipsychotics in MTFs
By 30 Day Equivalent Rxs, Oct 02 – Dec 02



Overall, the most commonly used atypical antipsychotic in MTFs is risperidone, followed by olanzapine and quetiapine (see Figure 3). There is low but increasing use of ziprasidone. Aripiprazole has not been on the market a sufficient period of time to assess its potential use.

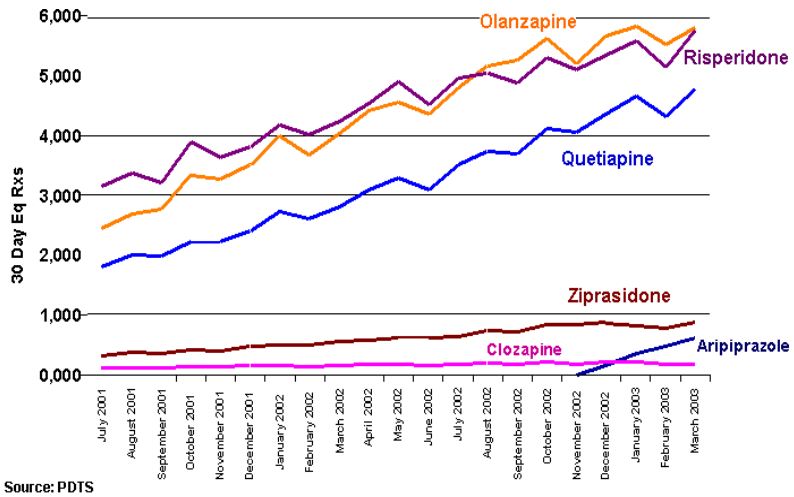
Figure 3: MTF 30 Day Equivalent Prescriptions for Atypical Antipsychotics
Jul 01 – Mar 03



Source: PDTS

In the retail network, olanzapine and risperidone are the most commonly used atypical antipsychotics, followed by quetiapine (see Figure 4). Ziprasidone use is again relatively low, but increasing. Aripiprazole use is increasing at a faster rate than in MTFs.

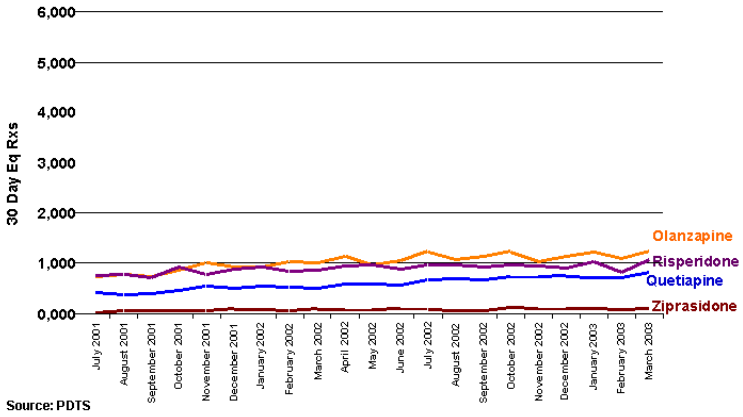
Figure 4: Retail Network 30 Day Equivalent Prescriptions for Atypical Antipsychotics
Jul 01 – Mar 03



Source: PDTS

In the mail order program, olanzapine, risperidone, and quetiapine are the most commonly used atypical antipsychotics (Figure 5). Aripiprazole was not added to the mail order formulary until March 03 and does not show on this graph.

Figure 5: Mail Order 30 Day Equivalent Prescriptions for Atypical Antipsychotics
Jul 01 – Mar 03



Efficacy

- *Schizophrenia and related psychoses* – There do not appear to be any clinically relevant differences among the atypical agents with respect to overall efficacy and treatment of positive symptoms (e.g., delusions and hallucinations), although individual patients may respond better to one than another. There is stronger evidence with olanzapine than with other atypical antipsychotics to support efficacy in treating negative symptoms (e.g., apathy, lack of motivation, lack of interpersonal and social interaction), based on olanzapine's demonstrated superiority to a typical antipsychotic (haloperidol) in reducing negative symptom scores in both individual short-term and long-term trials. Risperidone has also demonstrated superiority to haloperidol in reducing negative symptom scores based on long-term trials and pooled data from short-term trials. Less clinical evidence is available for quetiapine, ziprasidone, and aripiprazole.

  Atypical antipsychotics have also been shown to have positive effects on neurocognitive functioning (e.g., memory and attention) and mood symptoms (e.g., depressed mood) in patients with schizophrenia or related psychoses; however, the relative efficacy of specific atypical antipsychotics in these domains is still unclear.

- *Dementia* – Dementia is generally defined as a progressive decline in intellectual functioning that impedes normal activities; Alzheimer's dementia is the most common type. The FDA has not yet approved any drugs specifically for the "behavioral and psychological symptoms of dementia" (BPSD). Consensus statements from various national groups recommend antipsychotics as the only available pharmacological treatment for psychotic symptoms of *BPSD*. There is no evidence that any one atypical antipsychotic is more efficacious in one type of dementia than another. Risperidone and olanzapine have been shown to be

efficacious in reducing BPSD in published randomized controlled trials. Other atypical antipsychotics lack published data.

- *Bipolar mania* – According to the American Psychiatric Association Guideline for the Treatment of Patients with Bipolar Disorder (2000), first line treatment for more severe manic or mixed episodes of bipolar disorder is the initiation of lithium or valproate plus an antipsychotic. For less ill patients, monotherapy with lithium, valproate, or an antipsychotic may suffice. The guidelines state that atypical antipsychotics are preferred over typical antipsychotics due to their side effect profile. Olanzapine is the only atypical antipsychotic with an FDA-approved indication for the treatment of bipolar mania. It has been shown to be of comparable efficacy to lithium in the reduction of manic symptoms in one clinical trial and superior to divalproex in another. Olanzapine has also been shown to be superior to placebo as adjunctive therapy with a mood stabilizer (lithium or divalproex). Risperidone has been shown to be superior compared to placebo both as monotherapy and as adjunctive therapy with a mood stabilizer. A recently published trial (April 2003) with ziprasidone showed efficacy for monotherapy. Large trials with aripiprazole and quetiapine (either as monotherapy or as adjunctive therapy) have been performed, but results are not yet available as full publications.
- *Psychiatric and behavioral disorders in children and adolescents* – None of the atypical antipsychotics are currently approved for the treatment of children and adolescents. Multiple small trials, uncontrolled trials, case reports, and case series focus on the use of atypical antipsychotics (most commonly risperidone) in pediatric patients for the treatment of a wide variety of conditions. In large ($n \geq 30$) controlled trials, risperidone has been shown to be efficacious for the treatment of conduct disorder in children with mental retardation (two trials) and for the treatment of aggressive behavior in autistic children (one trial). Quetiapine has been shown to be efficacious as adjunctive therapy for bipolar mania with divalproex in adolescents 12-18 years of age.

Safety/Tolerability

Adverse effect profiles differ substantially among atypical antipsychotics. Provider comments with respect to the safety and/or tolerability of specific agents identified the following concerns: olanzapine (weight gain, diabetes, cholesterol/triglyceride elevations, sedation), quetiapine (weight gain, diabetes, cholesterol/triglyceride elevations), risperidone (EPS, prolactin), ziprasidone (cardiac effects, "emerging case reports of EPS"). Providers commented favorably on the ease of dosing olanzapine compared to quetiapine, and their tendency to use once daily drugs first line. Of the agents, olanzapine and aripiprazole are generally dosed once daily, risperidone can be dosed once or twice daily; and ziprasidone and quetiapine are typically dosed twice daily. Aripiprazole was not yet approved when the survey was completed and was not mentioned by survey responders.

- *Extrapyramidal symptoms* (EPS) are abnormal, involuntary movements associated with antipsychotic treatment. Their occurrence is related to D2 receptor binding in the nigrostriatal pathway; atypical antipsychotics have a higher 5-HT-2 / D2

binding ratio than typical antipsychotics, and thus a lower risk of EPS. This lower risk of EPS is considered to be the defining characteristic of "atypicality." Both olanzapine and risperidone may have increased binding affinity for D2 receptors at higher doses, but in the case of olanzapine, high antimuscarinic activity may limit EPS symptoms.

Of the atypical antipsychotics, risperidone in general appears to have a higher risk of EPS than other agents, although at lower doses (<6 mg/day) this may not be true. Tarsy et al (2002) provide a tentative ranking of EPS risk (from highest to lowest) as follows: Risperidone > olanzapine = ziprasidone > quetiapine > clozapine. Aripiprazole was not included in this review; EPS risk appears low in published trials to date. Accurate determination rates of EPS may be complicated by the presence of carryover EPS effects from previous antipsychotic treatment, particularly in short trials with minimal or no washout periods.

- *Tardive dyskinesia* (TD) is a late-appearing and generally irreversible complication of treatment with long-term antipsychotics, consisting of abnormal postures and involuntary movements of the face, eyes, tongue, trunk, or limbs. Up to 25% of patients may develop TD with cumulative use of typical antipsychotics. Sustained EPS is thought to be a risk factor for the development of TD. In general, atypical antipsychotics appear to have a lower risk of TD than typical antipsychotics. Both olanzapine and risperidone have been shown to be associated with a lower risk of TD than haloperidol. There are no long-term head-to-head studies between atypical antipsychotics addressing the risk of TD and limited long-term data with other atypical antipsychotics.
- *Weight gain* has been reported with a number of atypical antipsychotics, including olanzapine, quetiapine, and risperidone. Allison et al (1999) analyzed clinical trials with atypical antipsychotics and made the following estimates of mean weight gain at 10 weeks (6 weeks for quetiapine, which lacked longer trials; all estimates at midpoint of the standard dosing range): 4.15 kg olanzapine, 2.18 kg quetiapine, 2.10 kg risperidone, 1.08 kg haloperidol, 0.04 kg ziprasidone, -0.74 kg placebo. Aripiprazole was not included in this analysis: the mean weight gain in 4- to 6-week placebo-controlled trials with aripiprazole was 0.71 kg. Later studies and other analyses typically show the same rank order; head-to-head studies comparing olanzapine and risperidone typically demonstrate more weight gain with olanzapine. Weight gain is problematic not only because of adverse health consequences, but because it is frequently associated with lack of adherence to medication.
- *Hyperlipidemia* has been reported with atypical antipsychotics, most commonly with olanzapine, but also with risperidone and quetiapine. Olanzapine and risperidone have been most commonly compared. Increases in total cholesterol appear less frequent with risperidone than with olanzapine; there is little published data from large trials focusing on specific lipid effects (e.g., LDL, HDL, or triglycerides).
- *Treatment-emergent diabetes* has also been reported with atypical antipsychotics. The mechanism is unclear, as is the relationship of treatment-emergent diabetes

with weight gain and hyperlipidemia. In general, schizophrenic patients are at increased risk for hyperglycemia and/or diabetes compared to the general population, whether due to lifestyle factors or as a consequence of the disease process. Diabetes appears to occur more frequently in schizophrenic patients receiving atypical antipsychotics than those receiving typical antipsychotics.

Olanzapine has been associated with the greatest increase in risk of hyperglycemia and diabetes among the atypical antipsychotics reviewed, based on epidemiological studies. Risperidone has also been associated with increased risk, but less consistently and at an apparently lower rate than olanzapine. In one large case-control study (19,637 patients diagnosed and treated for schizophrenia between 1987 and 2000) the incidence of treatment-emergent diabetes per 1000 person-years was 10 for olanzapine (95% CI 5.2 – 19.2), 5.4 for risperidone (95% CI 3.0 – 9.8), and 5.1 for typical antipsychotics (95% CI 4.5-5.8) [Koro et al, 2002]. Data with other atypical antipsychotics is limited.

- *QT interval prolongation* – Labeling for ziprasidone contains a warning about the drug's potential for QTc-interval prolongation and risk of *torsade de pointes* (a potentially fatal arrhythmia) based on the occurrence of prolonged QTc intervals in Phase 2/3 clinical trials. Data from an FDA-requested study assessing the effect of maximum recommended doses of oral ziprasidone, risperidone, olanzapine, quetiapine, thioridazine, and haloperidol on the QTc interval in patients with schizophrenia is available from the FDA Psychopharmacological Drugs Advisory Committee Briefing Document for ziprasidone, July 19, 2000 (available at: www.fda.gov/ohrms/dockets/ac/00/backgrd/3619b1.htm). In this open-label, parallel group trial, mean changes in QTc interval occurred in the following rank order, from greatest to least: thioridazine > ziprasidone > quetiapine > risperidone > olanzapine > haloperidol. While ziprasidone was associated with the greatest increase in QTc interval among the atypical antipsychotics studied, no patients had a QTc > 500 msec. The study also included an analysis of the effect of co-administration of metabolic inhibitors for each product. Co-administration of ziprasidone with its metabolic inhibitor, ketoconazole, did not lead to any further prolongation of the QTc despite an increase in serum concentration. According to the manufacturer, there have been no reports of *torsades de pointes* during post-marketing experience with ziprasidone. Ziprasidone has been taken by approximately 150,000 patients since it was approved (Weiden et al, 2002).

  Product labeling for risperidone reports lengthened QTc intervals in some patients but no mean increase even at higher than normal doses. No increases in QTc interval are reported in product labeling for aripiprazole, olanzapine, or quetiapine.

- *Cerebrovascular events* – Results of an analysis of 4 placebo-controlled trials (4-12 weeks in duration) in more than 1200 patients with Alzheimer's disease or vascular dementia receiving risperidone were recently released. The overall risk of cerebrovascular adverse events was 4% in the risperidone-treated group compared to 2% in the placebo group; four patients died in the risperidone group vs. one patient in the placebo group. A further search of postmarketing databases

revealed 37 cases of cerebrovascular adverse events in elderly dementia patients taking risperidone, of which 16 (43%) were fatal.

The manufacturer of risperidone recently stated that it intends to send letters to U.S. physicians advising them of the possibility of increased risk of stroke among elderly patients taking risperidone and to make changes to product labeling more clearly outlining available information about risk in elderly patients. A similar warning was released in Canada last October, with a summary and review of available information published in the November 2002 issue of the Canadian Medical Association Journal (Wooltorton, 2002). The Canadian letter to physicians is available at: http://www.hc-sc.gc.ca/hpb-dgps/therapeut/zfiles/english/advisory/industry/risperdal1_e.pdf.

Whether other atypical antipsychotic agents are associated with similar cerebrovascular risks is unknown.

- *Prolactin elevation* - Blockade of D2 receptors in the hypothalamus can result in increased prolactin secretion, which can lead to breast swelling, tenderness, and discharge; menstrual cycle irregularity or amenorrhea; sexual dysfunction; anovulation; and osteoporosis. Elevated prolactin levels do not always correlate with the presence of symptoms; long-term consequences of elevated prolactin are unclear. Atypical antipsychotics have a lower risk for causing prolactin elevation than typical antipsychotics, due to selectivity in the limbic system and higher 5-HT2 to D2 binding ratios. Of the atypical antipsychotics, risperidone has been associated with the largest increases in prolactin levels.
- *Other adverse effects* considered by the Council included the risk of orthostatic hypotension, anticholinergic effects, somnolence, cataracts, sexual dysfunction, priapism, and seizure.

Cost

MTFs spent about $11.3 million on atypical antipsychotics in FY 02: $5.6M for olanzapine, $3.8M for risperidone, $1.4M for quetiapine, $0.4M for ziprasidone, and $0.1M for clozapine. The average cost per day (tabs/caps only) is given in Table 3 below:

Table 3 - Average cost per tab/cap, tab/caps per day, and average cost per day for atypical antipsychotics in MTFs

	Average cost per tab/cap (PV data Dec 02-Feb 03)	Average tabs/caps per day** (PDTS data Jan 03-Mar 03)	Average cost per day
Aripiprazole*	$7.13	1.01	$7.21
Olanzapine	$4.22	1.33	$5.61
Quetiapine	$1.23	2.14	$2.64
Risperidone	$1.88	1.60	$3.01
Ziprasidone	$2.32	1.97	$4.56

* Limited data for aripiprazole
** Based on days supply. Results are consistent with those calculated for the retail network and mail order and with an older analysis based on directions for use.

The Council considered BPAs or incentive purchase agreement offers from the manufacturers of olanzapine, quetiapine, and risperidone. Offers differed considerably regarding the basis for price discounts and the considerations required by the manufacturers. A cost impact analysis by LCDR Ted Briski showed that annual cost avoidance ranging from $0.7 million to $1 million (based on current usage) could be attained by accepting two of the three offers.

After weighing relative usage, clinical factors, and economic factors, the Council voted to add risperidone and quetiapine to the BCF. The Council noted the following:

- Risperidone is by far the most commonly used atypical antipsychotic in the pediatric population, an age group in which use of this drug class is relatively high. Ensuring uniform availability of this agent across the system may benefit military personnel with children, who commonly move from MTF to MTF.
- The recent reports of an increased incidence of stroke in elderly patients with dementia receiving risperidone may lead to preferential use of other atypical antipsychotics in elderly patients (although there are no data indicating whether the same effect occurs with other atypical antipsychotics). Taken along with the general inter-patient variability in this drug class and the higher incidence of EPS and prolactin elevation with risperidone, this argues for the presence of a second agent on the BCF.
- Data for differences in efficacy among the various agents are not compelling, particularly considering the likelihood of use in conditions other than schizophrenia. However, adverse effect profiles differ considerably. All of the most commonly used medications have adverse effect concerns. Data on the newer agents, ziprasidone and aripiprazole, which may avoid some common adverse affects, are limited, and usage is low.
- Quetiapine and risperidone are the least costly agents on a cost per day basis.
- MTFs are free to add or retain additional atypical antipsychotics on their formularies if required locally.

C. *Topical Immunomodulators (TIMS)*

In November 2002, the DoD P&T Executive Council agreed that TIMS are a unique class and have a substantial place in therapy for the treatment of atopic dermatitis (AD), however there was concern regarding the cost of these agents and the potential for overuse. The Council agreed to consider one or both of these medications for addition to the BCF after procurement options were explored.

Efficacy – Randomized controlled clinical trials demonstrate that both agents are more efficacious than placebo in the treatment of AD. Tacrolimus, an ointment, appears to be as efficacious as a medium potency topical corticosteroid (TCS) whereas pimecrolimus, a cream, is as efficacious as a low potency TCS. Tacrolimus is indicated for moderate to severe AD while pimecrolimus is indicated for mild to moderate AD. Ninety percent of patients have mild to moderate AD and the rest are moderate to severe. Most of the use is in the very young (ages 0-4) and elderly (ages 65+).

Safety/Tolerability – Neither drug has clinically significant adverse effects that cause the patients to discontinue use. The drugs are not systemically absorbed, so they can be used long term without potential problems associated with long-term TCS use. TIMS can also be used on sensitive body areas such as the face and intertriginous regions where one would not want to use a TCS. Because pimecrolimus is a cream and less occlusive, it is preferred over tacrolimus for areas like the face, perioribital eyelids, and flexural and groin areas.

Other – Provider response was markedly positive regarding the prospect of having an alternative to TCSs on MTF formularies. At the same time, providers noted that these would not take the place of the low potency TCSs or other initial therapies for mild AD. Of 68 provider responses, 60 recommended adding one or both agents to the BCF. Of these 60 responses, 33 preferred pimecrolimus, 6 preferred tacrolimus, and the rest either had no preference or wanted both agents on the BCF. Pimecrolimus prescription fills are increasing at all points of service (MTF, TMOP, and retail). Pimecrolimus is currently on 49 percent of all MTF formularies. Tacrolimus is on 25 percent of MTF formularies; tacrolimus prescription fills for all points of service have leveled off at a point well below pimecrolimus.

Cost – Novartis offered an incentive agreement contingent on pimecrolimus being added to the BCF. The agreement provides a discount on all future purchases.

The Council voted unanimously to add pimecrolimus to the BCF. After being reviewed by dermatologists, a place in therapy (PIT) guide will be disseminated to the MTFs as a tool to help reduce potential inappropriate use.

8. REQUESTS FOR BCF CHANGES

A. *Nitroglycerin Products on the BCF*

The American College of Cardiology/American Heart Association currently considers nitroglycerin as third-line treatment for *chronic* symptoms of angina. Despite this third-line consideration for use, nitroglycerin transdermal systems currently account for approximately 8,000 prescriptions monthly in the MHS, second only to the sublingual tablets (approximately 15,000 prescriptions/month). Other nitroglycerin preparations (translingual spray, sustained release capsules, and ointment) combined account for approximately 6,000 prescriptions/month. Current BCF nitroglycerin products include sublingual nitroglycerin tablets, translingual spray, and isosorbide dinitrate oral. The BCF does not contain a long acting nitroglycerin product.

Transdermal nitroglycerin systems are on 75% (86/114) of local MTF formularies. A DoD/VA joint contract for nitroglycerin transdermal systems from Schering provides the patches at a cost of $0.16/day ($4.89/month).

An analysis of MHS prescription data revealed a steadily increasing number of prescriptions for isosorbide mononitrate oral for all three points of service in the MHS (approximately 16,000 prescriptions/month combined). Isosorbide mononitrate oral is on 43% (49/114) of local MTF formularies. The DoD/VA currently has a joint contract for a generic once daily isosorbide mononitrate oral tablet at a cost ranging between $0.04 to $0.06/day, depending on strength.

The Council voted unanimously to add the contracted nitroglycerin transdermal system and the contracted once daily preparation of isosorbide mononitrate oral to the BCF, due to wide usage in the MHS and low cost.

B. *Administrative Changes Concerning the Process for Requests from the Field for BCF Changes*

In order for the PEC to provide support materials for agenda items to the Council members three weeks prior to the meeting, a deadline needs to be established for submission or requests for BCF changes. To allow sufficient time to complete an analysis and prepare a recommendation for any submitted request, the PEC recommended that the deadline for BCF change requests should be 6 weeks prior to the next regularly scheduled meeting. The Executive Council concurred with this recommendation.

A second issue concerned the potential need for individuals requesting the addition of an agent to the BCF to disclose whether they have a financial interest or other relationship with the manufacturer of the product that could be perceived as a conflict of interest. The purpose of this disclosure would not be to prevent the consideration of the request, but to provide the Council with information that would allow it to make a more informed and credible decision. It was initially proposed that a disclosure form should be required to accompany a request for a BCF change. Some Council members suggested that if disclosure forms are required for BCF change requests, the same type of disclosure should be required for input regarding other P&T actions. Council members were concerned that the paperwork burden would degrade the ability of the PEC to obtain input from providers. The Council voted to table this issue and tasked the PEC to clarify the necessary scope and process for obtaining disclosure statements on any input related to formulary decisions making. The PEC is to present a revised recommendation at the next meeting.

9. ADJOURNMENT

The meeting adjourned at 1500 hours. The next meeting will be held at TRICARE Management Activity (TMA), conference room 815, Skyline Building 6, 5111 Leesburg Pike, Falls Church, VA at 0800 on Tuesday, 5 August 2003. All agenda items should be submitted to the co-chairs no later than 18 July 2003.

MCCS-GPE **6 MARCH 2003**

MEMORANDUM FOR: Executive Director, TRICARE Management Activity (TMA)

SUBJECT: Minutes of the Department of Defense (DoD) Pharmacy and Therapeutics (P&T) Committee Meeting

1. A meeting of the DoD P&T Committee convened at 0800 hours on 6 March 2003, at the DoD Pharmacoeconomic Center, Fort Sam Houston, Texas.

2. VOTING MEMBERS PRESENT

CDR Terrance Egland, MC	DoD P& T Committee Co-chair
COL Daniel D. Remund, MS	DoD P& T Committee Co-chair
COL Joel Schmidt, MC	Army
MAJ Travis Watson, MS	Army
COL John R. Downs, MC	Air Force
COL Mark Nadeau, MC (for COL Bill Sykora, MC)	Air Force
LtCol George Jones, BSC	Air Force
CAPT Matt Nutaitis, MC	Navy
CDR Mark Richerson, MSC	Navy
CAPT Robert Rist	Coast Guard
Mike Valentino	Department of Veterans Affairs
Dr. Trevor Rabie	Uniformed Services Family Health Plan
COL Doreen Lounsbery, MC	Army

VOTING MEMBERS ABSENT

None	

OTHERS PRESENT

COL William Davies, MS	DoD Pharmacy Program Director, TMA
Howard Altschwager	Deputy General Counsel, TMA
COL Mike Heath, MS	Army Pharmacy Consultant, Chairman Pharmacy Board of Directors
CAPT Betsy Nolan, MSC	Navy Pharmacy Specialty Leader
David Chicoine	Uniformed Services Family Health Plan
CAPT Joe Torkildson, MC, USN	DoD Pharmacoeconomic Center
CDR Denise Graham, MSC, USN	DoD Pharmacoeconomic Center
LtCol Dave Bennett, USAF, BSC	DoD Pharmacoeconomic Center
LtCol Barb Roach, USAF, MC	DoD Pharmacoeconomic Center
CDR (sel) Ted Briski, MSC, USN	DoD Pharmacoeconomic Center
Shana Trice	DoD Pharmacoeconomic Center
David Bretzke	DoD Pharmacoeconomic Center
Eugene Moore	DoD Pharmacoeconomic Center
Angela Allerman	DoD Pharmacoeconomic Center
Lisa LeGette	Express Scripts
Mark Hughes	Express Scripts
MAJ John Howe, MS	Defense Supply Center Philadelphia
Kathy Tortorice	Department of Veterans Affairs
Shannon Rogers	Humana
William Hudson	Humana
Gene Lakey	TriWest
Ray Nan Berry (via T-Con)	Health Net Federal Services
Ron McDonald (via T-Con)	Sierra

3. **REVIEW MINUTES OF LAST MEETING** – The minutes from the last meeting were accepted as written.

4. **INTERIM/ ADMINISTRATIVE DECISIONS** – Trovafloxacin was excluded from the NMOP/TMOP since its use is reserved for "patients with serious, life- or limb-threatening infections who receive their initial therapy in an inpatient health care facility," and is restricted to a two-week period.

5. **UNIFORM FORMULARY (UF) PROPOSED RULE**- COL William Davies, DoD Pharmacy Program Director, TMA, stated that the responses to the public comments on the proposed rule are nearly finalized and will undergo a legal review.

6. **BCF AND TRICARE MAIL ORDER PHARMACY (TMOP) FORMULARY ISSUES** – The Committee determined the TMOP formulary status, TMOP or retail network formulary restrictions (quantity limits or prior authorization), and Basic Core Formulary (BCF) status for 6 new drugs or formulations (see Appendix A). The PEC also presented brief information on fourteen additional new drugs or formulations not requiring a complete review by the Committee (see Appendix B). The Committee agreed that no further review was required.

7. MAIL ORDER AND RETAIL NETWORK ISSUES

A. *Implementation of the TMOP on 1 March 2003* - COL Davies (TMA) and Lisa LeGette from Express Scripts (the contractor for the TMOP program) provided an overview of the implementation of the TRICARE Mail Order Pharmacy program, and the progress of the changeover from the previous National Mail Order Pharmacy (NMOP) program. Shana Trice (PEC) reviewed the new TMOP Formulary page on the PEC website and explained changes from the old NMOP Formulary page. She also discussed revisions to the DoD Quantity Limits page to better reflect implementation of the quantity limits at the TMOP.

The URL for the TMOP Formulary page is: www.pec.ha.osd.mil/TMOP/TMOPhome.htm. Comprehensive benefit information for the TMOP may be found on the TRICARE website at: http://www.tricare.osd.mil/pharmacy/tmop.cfm, while the Express-Scripts website (www.express-scripts.com; click on the DoD seal) provides beneficiaries with the ability to register for the TMOP online, download registration forms, order refills, check order status, etc.

B. *New "line extension" rule for the TMOP* – The Council agreed that newly approved combination products involving addition of a diuretic to another antihypertensive medication may be automatically added to the TMOP Formulary as a line extension, pending confirmation by the Committee at the next scheduled meeting. The Committee asked for a review of "line extension rules" for the TMOP at the next meeting in May 2003. The rules currently in effect are those previously approved for the NMOP; however, there are operational differences between the two programs that affect the manner in which the rules are applied.

8. PRIOR AUTHORIZATIONS (PAs)

The Committee approved prior authorization criteria for adalimumab (Humira) and modifications to prior authorization criteria for etanercept (Enbrel) and anakinra (Kineret) (see Appendix D).

9. CONTROLLED DISTRIBUTION OF PRESCRIPTION DRUGS – Buprenorphine & buprenorphine/naloxone (Subutex/Suboxone) are subject to a controlled distribution process, but it is not clear to the Committee that these medications are covered under TRICARE rules. Enfuvirtide (Fuzeon) a new HIV medication will be manufactured on a limited scale, however the distribution process is unknown. Further information on both these products should be available by the next meeting. Peginterferon-alfa 2b (PEG-Intron) and etanercept (Enbrel) are no longer under controlled distribution.

10. ADJOURNMENT – The meeting adjourned at 1130 hours. The next meeting will be held at Fort Sam Houston, TX at 0800 on Wednesday, 7 May 2003. All agenda items should be submitted to the co-chairs no later than 18 April 2003.

List of Appendices

APPENDIX A: NEWLY APPROVED DRUGS CONSIDERED FOR THE TRICARE MAIL ORDER PHARMACY FORMULARY AND DOD BASIC CORE FORMULARY

Generic name (Trade name; manufacturer)	**FDA approval date, drug class, FDA-approved indication**	**TMOP Formulary status**	**TMOP and/or retail network formulary restrictions**	**BCF status**
Nitazoxanide 100 mg/5 mL oral suspension (Alinia; Romark Labs)	22 Nov 02: Treatment of diarrhea caused by *Cryptosporidium parvum* and *Giardia lamblia*, in pediatric patients 1 through 11 years of age. Nitazoxanide is given every 12 hours for 3 days. Nitazoxanide is the first anti-parasitic product approved specifically for treating cryptosporidiosis and the only drug approved for treatment of giardiasis in ages 1-11 years that is available in a suspension formulation. A tablet formulation of nitazoxanide for adults with intestinal parasites is "approvable" at the FDA.	Added to the TMOP Formulary	**Quantity Limits** General rule applies **Prior Authorization:** None	Not added to the BCF **Similar BCF agents:** Metronidazole oral tablets; requires extemporaneous compounding to make a suspension.
Eletriptan tablets (Relpax; Pfizer)	26 Dec 02: Indicated for the acute treatment of migraine attacks with and without aura in adults. This is the 7th 5-HT receptor agonist (triptan) marketed.	Added to the TMOP Formulary	**Quantity Limits** Quantity limits exist for other triptans. Packaged in 12's. **Retail**: 12 tablets/30 days" **TMOP:** 36 tablets/90 days **Prior Authorization** None	Not added to the BCF **Similar BCF agents:** sumatriptan oral tablets and auto-injector. **Note:** A contracting initiative for the triptan class is underway.
Aripiprazole tablets (Abilify; BMS)	15 Nov 02: Atypical antipsychotic indicated for the treatment of schizophrenia. Unlike other atypical antipsychotics, aripiprazole functions as a partial agonist at dopamine D_2 receptors; the clinical significance of this difference is unknown.	Added to the TMOP Formulary	**Quantity Limits** General rule applies **Prior Authorization** None	Not added to the BCF **Similar BCF agents**: None **Note:** Addition of one or more atypical antipsychotics to the BCF is under discussion.
Teriparitide (rDNA origin) injection (Forteo; Lilly)	26 Nov 02: Recombinant parathyroid hormone (PTH); stimulates new bone formation by increasing osteoblast activity. Teriparitide is indicated for the treatment of men and postmenopausal women with osteoporosis who are at high risk for fracture, including those with a history of osteoporotic fracture, multiple risk factors for fracture, or who have failed or are intolerant of previous osteoporosis therapy. Once-daily subcutaneous administration; may be self-injected. The injection device is similar to Lilly's insulin pen. Requires refrigeration. Black box warning for osteosarcoma in rodent studies. Patient medication guide must be dispensed with the product.	Added to the TMOP Formulary & TMOP Covered Injectables List	**Quantity Limits** General rule applies **Prior Authorization** None	Not added to the BCF **Similar BCF agents**: Alendronate tablets are on the BCF. Potential contracting initiative for alendronate or risedronate is under consideration.

Generic name (Trade name; manufacturer)	**FDA approval date, drug class, FDA-approved indication**	**TMOP Formulary status**	**TMOP and/or retail network formulary restrictions**	**BCF status**
Atomoxetine capsules (Strattera; Lilly)	26 Nov 02: Treatment of Attention-Deficit/Hyperactivity Disorder (ADHD) in children (down to age 6 years). Atomoxetine is a highly selective norepinephrine re-uptake inhibitor. It is the only non-controlled medication approved for the treatment of ADHD and the only medication approved for the treatment of ADHD in adults.	Added to the TMOP Formulary	**Quantity Limits** General rule applies **Prior Authorization** None	Not added to the BCF **Similar BCF agents:** Existing products for ADHD are all Schedule II controlled substances: methylphenidate ER (specific brand is Concerta); methylphenidate IR; D,L amphetamine ER (Adderall XR).
Adalimumab injection (Humira; Abbott)	2 Jan 03: Monoclonal antibody that binds to tumor necrosis factor (TNF) alpha. Indicated for reducing the signs and symptoms and inhibiting the progression of structural damage in adults with moderately to severely active RA who have had an inadequate response to one or more disease-modifying anti-rheumatic drugs (DMARDs). Can be used alone or in combination with methotrexate. Administered as a single dose 40 mg subcutaneous (SQ) injection every two weeks (patients not on methotrexate may require weekly administration). May be self-injected. Other similar biologics – etanercept, and infliximab, both TNF inhibitors, and anakinra, an interleukin-1 inhibitor – are also indicated for RA. Etanercept is also indicated for juvenile RA and psoriatic arthritis; infliximab for Crohn's disease. Etanercept (Enbrel) is administered SQ twice a week; infliximab (Remicade) as a monthly IV infusion, and anakinra (Kineret) as a daily SQ injection. Adalimumab contains the same black box warnings as other TNF blockers for emergence of serious infections during treatment, including disseminated or extrapulmonary tuberculosis.	Added to the TMOP Formulary & Covered Injectables List	**Quantity Limits** **TMOP**: 6 syringes per 6 weeks (3 packs of 2 syringes) **Retail:** 4 syringes per 4 weeks (2 packs of 2 syringes) **Note**: the quantity limits allow for the possibility of once weekly administration of adalimumab in some patients. Quantity limits are in place for both etanercept and anakinra. **Prior Authorization** ▪ Yes. See Appendix D for criteria.	Not added to the BCF **Similar BCF agents**: none

APPENDIX B: NEWLY APPROVED DRUGS NOT REQUIRING FULL REVIEW BY THE P&T COMMITTEE

Generic name (Trade name; manufacturer)	**Comments**
Isotretinoin capsules (Amnesteem; Bertek); (Sotret; Ranbaxy)	AB rated generics to Accutane (Roche brand of isotretinoin). Isotretinoin is excluded from the TMOP Formulary.
Ciprofloxacin extended-release tablets (Cipro XR; Bayer)	Approved for uncomplicated UTI caused *by E. coli*, *Proteus*, *Enterococcus*, and *Staphylococcus*; 3-day regimen. Automatically added to TMOP Formulary as a line extension. Ciprofloxacin is not on the BCF.
Stavudine extended release capsules (Zerit XR; BMS)	Nucleoside reverse transcriptase inhibitor for HIV. Automatically added to TMOP Formulary as a line extension. Stavudine is not on the BCF.
Alprazolam extended release capsules (Xanax XR; Pharmacia)	Approved for panic disorder. Automatically added to TMOP Formulary as a line extension. Alprazolam is not on the BCF.
Alpha-1 proteinase inhibitor, human injection (Aralast; Baxter/Alpha)	Orphan drug for hereditary emphysema/alpha 1 antitrypsin deficiency. Requires IV infusion. Not considered for the TMOP Covered Injectables List since it is not designed for self-administration. Not considered for the BCF due to the specialized nature of the indication.
Testosterone gel 1% topical (Testim; Auxilium Pharmaceuticals)	Approved for treatment of primary hypogonadism; 2nd testosterone gel on the market. Not generically substitutable for Androgel; both are reference listed drugs. Automatically added to TMOP Formulary as a line extension. Schedule III controlled medication. Although the general rule limits controlled medications to a 30-day supply at the TMOP, Testim falls under an already established exception to this rule that provides for up to a 90-day supply at the TMOP for commercially available topical testosterone products. Testosterone gel is not on the BCF.
Azelaic acid gel 15% topical (Finacea; Berlex)	Approved for mild to moderate rosacea. A similar product, azelaic acid 20% cream (Fineven; Berlex), approved for acne, is already available from the TMOP. Automatically added to TMOP Formulary as a line extension. Azelaic acid products are not on the BCF.
70% insulin aspart protamine suspension/30% insulin aspart injection (Novolog Mix 70/30 vials & pens; Novo Nordisk)	Biphasic insulin produced by adding protamine to Novolog. Automatically added to TMOP Formulary as a line extension.
Insulin aspart injection (Novolog flex pen; Novo Nordisk)	New packaging for insulin aspart. Automatically added to TMOP Formulary as a line extension.
Alefacept injection (Amevive; Biogen)	Biologic for moderate to severe plaque psoriasis given as a weekly IV bolus or IM injection. Not considered for the TMOP Covered Injectables List since it is not designed for self-administration. Not considered for the BCF due to the specialized nature of the indication.
Ribavirin capsules (Copegus; Roche)	Roche brand of ribavirin for use in combination with pegylated interferon. The Schering brand of ribavirin (Rebetol) is already available from the TMOP. Automatically added to TMOP Formulary as a line extension. Ribavirin is not on the BCF.
Diltiazem graded release tablet (Cardizem LA; Biovail)	New controlled release once-daily formulation of diltiazem; may be dosed in the morning or at bedtime. Not generically substitutable for Cardizem CD or Tiazac. Anticipated availability April 2003. Automatically added to TMOP Formulary as a line extension. Tiazac is the BCF selection for a once-daily diltiazem product.
Cyclobenzaprine tablets (Flexeril; McNeil)	New lower 5 mg dosage form. Automatically added to TMOP Formulary as a line extension. Cyclobenzaprine is not on the BCF.
Eprosartan/HCTZ tablets (Teveten HCT; GSK)	New combination of an angiotensin receptor blocker with hydrochlorothiazide. Automatically added to TMOP Formulary as a line extension. A VA/DoD solicitation for angiotensin receptor blockers is in progress.

APPENDIX C: COMBINED SUMMARY OF FORMULARY CHANGES FROM THE DOD P&T EXECUTIVE COUNCIL MEETING AND THE DOD P&T COMMITTEE MEETING

1. **BCF CHANGES**

   A. *Additions to the BCF*

      1) Chlorthalidone
      2) Benztropine
      3) Trihexyphenidyl
      4) Amantadine
      5) Lansoprazole
      6) Goserelin (Zoladex) 1- and 3-month products for the treatment of prostate cancer

   B. *Deletions, changes, clarifications or exclusions from the BCF* - None

2. **TMOP FORMULARY CHANGES**

   A. *Additions to the TMOP Formulary*

      1) Nitazoxanide oral suspension (Alinia; Romark Labs)
      2) Eletriptan tablets (Relpax; Pfizer) – quantity limits apply, see below
      3) Aripiprazole tablets (Abilify; BMS)
      4) Teriparitide (rDNA origin) injection (Forteo; Lilly) – added to the TMOP Covered Injectables List
      5) Atomoxetine capsules (Strattera; Lilly)
      6) Adalimumab injection (Humira; Abbott) – added to the TMOP Covered Injectables List with prior authorization criteria; quantity limits apply, see below

   B. *Exclusions from the TMOP Formulary*

      1) Trovafloxacin (Trovan; Pfizer) – specifically excluded from the TMOP Formulary, since its use is reserved for "patients with serious, life- or limb-threatening infections who receive their initial therapy in an inpatient health care facility," and is restricted to a two-week period.

   C. *Deletions, changes, or clarifications to the TMOP Formulary* - None

3. **QUANTITY LIMIT CHANGES (RETAIL NETWORK AND TMOP)**

   A. Quantity limit for eletriptan tablets (Relpax; Pfizer): 12 tablets (1 pack) per 30-day supply (retail); 36 tablets (3 packs) per 90-day supply (TMOP); consistent with existing quantity limits for other triptans (within limitations of package size)

   B. Quantity limit for adalimumab injection (Humira; Abbott): 4 syringes (2 packs of 2 syringes) per 4 weeks (retail); 6 syringes (3 packs of 2 syringes) per 6 weeks (TMOP)

4. **CHANGES TO THE TMOP PRIOR AUTHORIZATION PROGRAM**

   A. Prior authorization criteria established for adalimumab injection (Humira; Abbott) – see Appendix D

   B. Prior authorization criteria for etanercept and anakinra modified – see Appendix D

APPENDIX D: PRIOR AUTHORIZATION CRITERIA FOR ADALIMUMAB (HUMIRA) & CHANGES TO PRIOR AUTHORIZATION CRITERIA FOR ETANERCEPT (ENBREL) AND ANAKINRA (KINERET)

Drug	FDA Indications	New TMOP Prior Authorization Criteria
