This issue brief explores rates of preventive care use among military health care beneficiaries, by race and ethnicity.

- In 2020, non-service member white beneficiaries were the most likely to receive a flu shot in the last 12 months.
- White and Black beneficiaries, and beneficiaries in the “other” group were the most likely to get their blood pressure checked and know the result.
- Black women and women in the “other” group, ages 40 and older, were the most likely to get a mammogram.
- Hispanic, Black, and multiracial women were the most likely to get a pap smear. From 2016 – 2020, white and Asian women’s rate of pap smears significantly decreased.
- There were no differences in rates of prenatal care in the first trimester among race and ethnicity groups. However, Black women’s rate of first trimester prenatal care significantly increased.
Use of preventive care by race/ethnicity

Healthy People 2020’s goal for the rate of flu vaccination is 70 percent. Flu vaccination is mandatory for all service members (active duty personnel and inactive reservists), and in 2020, 91 percent of active duty and 95 percent of inactive reservists received the flu vaccine (Gehrke 2020). Accordingly, our analysis for this measure only includes non-service members.

In 2020, white beneficiaries and beneficiaries in the “other” race group were the only groups to meet the Healthy People 2020 goal or to have it within their margin of error (Figure 1). However, except for multiracial beneficiaries, all beneficiaries were within 10 percentage points of the goal. White beneficiaries were significantly more likely to have received a flu vaccine in the past 12 months compared with all race and ethnicity groups except for the “other” group.

Most beneficiaries reported that they had their blood pressure checked in the last two years and know the result (Figure 2). White, Black, and “other” beneficiaries exceeded the Healthy People 2020 goal of 92 percent for this measure; Asian and multiracial beneficiaries had it within their margin of error. Hispanic beneficiaries did not reach the goal. White, Black, and “other” beneficiaries were significantly more likely than Hispanic, Asian, and multiracial beneficiaries to have had their blood pressure checked.

Healthy People’s 2020 goal for women ages 40 and over having received a mammogram in the last two years is 81 percent. In 2020, across all race and ethnicity groups, women ages 40 and over met or exceeded the goal or had it within their margin of error (Figure 3). Black women and women in the “other” race group had the highest rates and were significantly more likely to have received the test than Asian women, who had the lowest rate.

Note: The standard error bars in the figure indicate the 95 percent confidence interval for each group.
* Statistically significant difference from Black women and women in the “other” race group, \( p < 0.05 \).
Healthy People 2020’s goal for the rate of adult women who received a cervical cancer screening in the last three years is 93 percent. No race and ethnicity group met this goal in 2020, which could be partly because this measure only asks women about pap smears, whereas the Healthy People 2020 goal could be met by either receiving HPV tests or pap smears. Hispanic, Black, and multiracial women were significantly more likely than white, Asian, and “other” women to have received a pap smear (Figure 4). Furthermore, white and Asian women had falling rates of pap smears from 2016 to 2020 (Figure 5). Both groups were significantly less likely to have received the test in 2020 than in 2016.

Healthy People 2020’s goal for the rate of pregnant women receiving prenatal care in the first trimester is 85 percent. In 2020, white and Black pregnant women exceeded this target, and Hispanic pregnant women had it within their margin of error (Figure 6). We did not report percentages of beneficiaries who were Asian, multiracial, or in the “other” race group because of the small number of respondents for this measure. In addition, the rate of first trimester prenatal care among Black pregnant women trended upward over the five-year period, with significant increases of 19 percentage points between 2016 and 2020 and 23 percentage points between 2019 and 2020 (Figure 7).

Discussion

As shown in our analysis, certain racial and ethnic disparities in preventive care use vary depending on the type of care. For example, white beneficiaries were among the most likely to receive flu shots and blood pressure checks, but white women were among the least likely to get a pap smear. Similarly, although Black women were less likely than white women to receive a flu shot, they were more likely to get a mammogram and a pap smear. Given that Hispanic, Black, and multiracial women were also more likely to receive a pap smear, providers may be particularly encouraging them for the test, as Hispanic and Black women have the highest rates of cervical cancer in the general population (Centers for Disease Control and Prevention 2017). White and Asian women’s rates of pap smears declined between 2016 and 2020, which could be an ongoing trend and might indicate a need for more outreach to white and Asian women about pap smears.

DHA should continue to encourage its beneficiaries to get appropriate preventive care, but because racial and ethnic groups vary in which services they are receiving, DHA could consider a tailored approach. The agency could craft such an approach by examining our research and broader national research on the race and ethnicity groups least likely to receive certain types of preventive care; it could then use that information to more accurately assess the provision of care for those groups.

One critical element of reducing disparities in care is encouraging culturally sensitive care, which studies show can improve the care experience for people of color. According to the 2017 National Health Interview Survey, Black and Hispanic people were more likely than white people to say that it was somewhat or very important to have a provider who shared or understood their culture, and they were more likely to report that they rarely saw such providers (Terlizzi et al. 2019). DHA could address this by offering providers culturally sensitive resources and training, which could in turn reduce racial disparities in the use of preventive care.
